than £460,000 a year. Shrimps are fished for by *trawl nets*, and also by *hand nets*. The former are modifications of the beam trawl adapted for catching shrimps, the *mesh* being three-eighths of an inch from knot to knot, and the beam not more than 25 ft. in length. The *shank net* is very similar, the mouth of the net being, however, kept open by means of an oblong frame of iron or wood. This net is used precisely like a trawl, being dragged along the bottom, and while so dragged the frame is kept in a vertical position, the longer axis being horizontal. Such nets are frequently used from carts which are driven along in a few inches of water at low tide. In similar localities, a hand net, known as a *push* or *power net*, is used. This varies in different parts of the coast; generally speaking, it consists of a triangular net attached to a framework, the whole apparatus being fixed at the end of a long pole. This net is pushed in front of the shrimper in shallow water, at low tide, and is hence locally known as a *shove net*. On his back the shrimper carries a large basket for the reception of his shrimps. Crabs and lobsters are mainly fished for by baited pots, in reality basket-like arrangements, or traps, which afford facilities for the ingress but bar the egress of the crustacean. These pots and baskets are lowered to the bottom, often in fairly deep water on rocky ground, their position being indicated by buoys. At the end of several hours the fishermen revisit the grounds, examine the pots, remove the lobsters or crabs that have been caught, and finally rebait their pots with stinking fish.

Showing how the bridles are attached

Fishing in the Future. A remarkable change has taken place in the fishing industry during the last thirty years. Previous to the advent of the steam fishing boat the smaller fishing villages were relatively far more important than they are at the present time, and the inshore fisherman who followed different classes of fishing at different seasons of the year—trawling, drift-netting, lining, and shrimping—is fast being replaced by the steam fisherman, who is a specialist pure and simple.

The bulk of the sea fish is landed at half a dozen large ports, such as Grimsby, Hull, Aberdeen, Yarmouth, Lowestoft, Fleetwood, and Liverpool, where access to the quays and wharves is available at all stages of the tide. The fish landed is usually sold at once by auction, and then forwarded to the markets at the large inland towns. The sailing smack owned partly or entirely by the man who sailed her is slowly but surely decreasing in numbers, and is being supplanted by the steamer, owned almost invariably by persons whose interest in the fisheries is mainly dependent upon their dividends. The fishermen are paid servants, or in some instances are paid by a share of the gross profits, the skipper and mate usually being paid by shares, the rest of the crew by a weekly wage. Already there are whispers of "rings" of buyers and dealers in fish; and who can say what the future of the inshore fisherman is to be?

Conditions of Success in the Future. The self-reliant and independent fisherman will therefore take heed of the future: only by embracing as far as may be practicable newer methods of fishing will he be able to compete successfully with his formidable rivals. The adoption of means of keeping his catch in good condition, and for securing its rapid transit to the market, the introduction of labour-saving devices for manipulating his gear, and, above all, the question of auxiliary propulsive methods to assist the uncertain winds, are all subjects which will imperatively demand his immediate and earnest attention.

Quite recently a society, called the Fisheries Organisation Society, of Queen Anne's Chambers, Westminster, has been formed to assist the inshore fishermen. The society does no trading itself, and makes no profit. It fosters co-operation among the fishermen, and forms local fishermen's co-operative societies for the better marketing of fish, the co-operative purchase, hire, and insurance of boats and gear, and for other matters connected with the welfare of the inshore fishermen. The society seems to have been formed on right lines; and it is to be hoped that its efforts to improve the condition of the inshore fishermen will meet with success.

Motor Fishing Craft. The possibility of the application of motor power to the sea-fishing industry has for some time been recognised, notably in Denmark, Scandinavia, and in the United States, and auxiliary internal-combustion engines have been applied to various classes of fishing smacks, and especially to deep-sea cutters of similar build, to the first-class English sailing trawler, to herring and to open line-fishing boats. This application must at present be regarded as having passed the experimental stage.

This must not be taken to mean that any sort of motor will do for a fishing boat. The problem is not quite so simple as that. The chief point to consider is whether the motor is required for propulsion only as in line-fishing, lobster and crab boats; or whether in addition to this main purpose the motor will be required, as in a sailing trawler, for trawling and hauling in the gear. In cases where the motor serves exclusively, or almost exclusively, for propulsion, it has already proved a success. In Scotland, where sailing trawling does not exist, and where the sailboats follow herring drifting and line-fishing, there was in 1901 only one motor boat taking part in the Scottish fisheries. In 1913 there were 523 so engaged. Of these, 182 were first-class boats (over 30 ft. keel), 313 second-class (18 to 30 ft. keel), and 28 were third-class boats (under 18 ft. keel). In England and Wales, where the sailing trawler predominates among sailing boats the progress is not nearly so rapid. In many instances motors have been installed in sailing trawlers by engineers unacquainted with the details of trawling; and although the motors have been serviceable for journeying to and fro from the fishing grounds, they have been a failure or only of very moderate success in trawling.

In the case of a trawler propelled otherwise than by sails—for example, a steam trawler [**6, 7, 8**]—when the vessel is fishing the trawl-warps lead

astern. In a sailing trawler when at work, the trawl-warp leads off the quarter, or even at right angles to the vessel's side, the skipper taking full advantage of wind and tide, and under such circumstances not much use can be made of the motor. Motors are not very popular at present among trawlers; and of the 153 motors installed in first-class English sailing vessels, only six are in vessels exclusively engaged in trawling. Of the 194 second-class vessels similarly equipped, 14 are exclusively trawlers.

Fishing Boat Motors. Motor engineers are now fully awake to the immense field for enterprise in the fishing industry, and there are a large number of British-made engines specially built for fishing boats. These engines run on petrol, paraffin, or crude oil. Among the leading makes of British engines are the Gardner, Kelvin, Thornycroft, Beardmore, Blackstone, Griffin, Parsons, Gleniffer, Grampian, and others. The Gardner, Thornycroft, Blackstone, and Griffin are paraffin engines on the four-cycle, and the Beardmore a paraffin engine on the two-cycle, principle. The Blackstone and Griffin work on the cheapest crude oil. In some districts of Scotland such as the Orkney Islands the fishermen instal second-hand motor-car engines in their boats. The horse-power of the engines installed in fishing boats ranges usually from 4 to 90 h.p., but is in the majority of cases below 10 h.p. Prices vary considerably, but as a rule an engine developing about seven-horse power can be obtained for between £65 and £90. A serviceable 13 to 15 horse-power engine ranges from £105 to £150, reversing gear being extra in each case.

The type of motor with detachable propellor [**9** and **10**] has not been adopted in the British Isles, but the type is represented in the case of small open fishing boats by a detachable motor of the Evinrude class.

Science and Sea Fishing. Of late years much attention has been given to the application of biological and hydrographical investigation to the elucidation of problems connected with the sea fisheries. Schools of "fishery science" have been established, notably at Bergen. Marine stations have been erected and equipped with the latest and most up-to-date apparatus for the study of applied marine biology; and practically every European country with a sea coast has one or more biological stations.

Institutions for the *hatching* of sea-fish have been erected on the coasts of Northern Europe and America, in England at Piel and Port Erin, and in Scotland at Aberdeen.

An International Council. Since 1902 an international council of scientific men has been engaged in the study of the causes that affect the harvest of the seas, and an enormous sum of money has been expended on fisheries investigation. The central laboratory is established at Christiania, and the office or bureau is at Copenhagen. Each country has, in addition, its own laboratories, steamers, and a trained staff of naturalists, hydrographers, chemists, and physicists, all working to a common end. Voluminous reports appear from time to time; and as the results to be obtained may have an important bearing on the fisheries, especially with reference to future legislation, it is well for the intelligent fisherman to learn something of the methods employed by expert scientific men, and the results which have up to the present been obtained.

Considerable attention is now being devoted to the *physical* as distinguished from the *biological* conditions which obtain in our seas. The methods of observation which were first of all practised by the famous "Challenger" expedition are being now amplified and applied to the determination of those changes in the physical condition of the seas which may reasonably be supposed to affect the presence of fish, and consequently the success or otherwise of the fisheries.

Physical Character of Sea Water. The characters of sea-water (apart from the plankton, which is separately considered) that are investigated are the *temperature*, *salinity*, *density*, and *gaseous contents*. By means of the first three data it is possible to trace the movements of large bodies of salt water, and to determine at given seasons of the year whence the water in our seas—the North Sea, English Channel, and Irish Sea, for instance—is derived. The movements of shoals of fish, such as the herring and anchovy, may possibly be correlated with the movements of bodies of water of a certain temperature and density. It is claimed that the anchovy fishing in the Scheldt is closely connected with the temperature of the sea, and that the arrival of the autumn herring off the Norwegian coast corresponds with the appearance of water of high temperature and medium salinity. At present these observations are carried out on the special steamers which are subsidised by the various Governments.

How the Sea is Analysed. The methods are briefly as follows: Soundings are taken to determine the depth and nature of the bottom; observations of temperature are made at the surface and at varying depths. Samples of the floating organisms are collected at the surface and at various depths. The temperature, pressure, and humidity of the atmosphere are also noted. Samples of water are also collected for analysis. The results are then collected and deductions drawn at the shore laboratories. Charts are published showing the lines of equal temperature (*isotherms*) and lines of equal salinity (*isosalines*).

It has been found that the waters in the English Channel are derived in February and May from the Bay of Biscay, in August from the Irish Sea, and in November from both sources. North Sea water is derived from three main sources: (*a*) North Atlantic water of high density enters chiefly from the north-west; (*b*) Baltic water of low density enters as a surface current from the Skagerack; and (*c*) North Sea water of medium salinity. There is also what is known as Bank water forming a fringe to the coast line. It consists of a mixture of Atlantic and

Baltic waters. There are various seasonal changes in the inflowing and outflowing currents, which prove that the North Sea fishing grounds are subject to periodical variations with respect to the water covering them. The ultimate bearing of these hydrographical observations on sea fishery problems is for the future to decide. They are still being carried on, and it would be premature to criticise the results until further information is at hand.

Drift Bottles and Surface Currents. The determination of the influences which affect the distribution of floating bodies has been largely accomplished by means of *drift bottles*: means of cork covered with paraffin-wax, a special voyage is made on a scientific steamer, and the bottles are thrown out at intervals of five minutes or so along certain lines which have been previously selected as likely to furnish important results. The rate at which the steamer travels being known, the distances at which the bottles are dropped overboard can be marked off on a chart. As the postcards return to the laboratory, the journeys made by the bottles can be traced. Some of the bottles are picked up very soon, others perform remarkable journeys. The effect of tidal currents and the wind on the distribution of surface organ-

Strong, short-necked bottles are weighted with a small quantity of sand, so that they are immersed with as little of the neck protruding as possible. Each bottle has enclosed in it a stamped postcard addressed to the laboratory from which the experiments are initiated. The postcard has a printed statement on it requesting the finder to fill in information as to the date and place of finding, and to post the card. It is found that in a somewhat circumscribed area, such as the Irish Sea, about one in every three bottles is picked up, and the postcards returned with the requisite information. A number of bottles being weighted and made watertight by isms is in this manner estimated, and the problem has a practical bearing, as will be seen later, in determining the most favourable locality for the *planting* of the fry from marine hatcheries.

The Plankton Investigations A word that is frequently used in all discussions on sea fishery matters is *plankton*. All organisms which merely drift and are consequently at the mercy of the wind and tide are included in the plankton, in contradistinction to those animals which, like fish, are capable of independent motion, and are therefore able to move against a tide or current. The *plankton* has been studied for a number of years,

and its constitution is fairly accurately known. It consists of minute plants, such as diatoms; various animalcules, small crustacea, especially those known as *copepoda*, the larvæ of free-swimming young stages of various worms, crustacea (crabs and lobsters), mussels, cockles, oysters, and other shellfish: and the floating eggs and larvæ of most of our food fish, the only notable exception being the herring, the eggs of which sink to the bottom, and develop there.

Now, the plankton, apart from interesting facts which are discussed later, is of considerable importance, insomuch as it serves as a direct source of food supply of some of our most valuable fish, notably the herring, pilchard, sprat, anchovy, mackerel, and others. There can be no reasonable doubt that the supply of these important fishes bears a direct relation to the amount of plankton present in the ocean.

Collection of Plankton. The plankton is collected by means of fine-meshed nets of silk bolting cloth, which are known as *tow nets*, having for their object the fishing out of plankton from a definite volume of sea-water. Of these nets the most successful is the vertical plankton net invented by Hensen [11]. This net, which is shaped like an inverted truncated cone, is lowered perpendicularly in the water to a given depth, and then raised to the surface, also perpendicularly. By this method a cylindrical column of water filters through the net, and its planktonic constituents are captured.

9. DANISH DEEP-SEA CUTTER WITH MOTOR AND LOOSELY SUSPENDED PROPELLER

The Quantitative Examination of Plankton. The volume of this cylindrical column of water can be estimated, since the filtration capacity of the net can be calculated, and the depth to which the net is sunk is known, as is also the area of the net opening. This being known, the number of organisms captured in the column of water through which the net has fished can be ascertained, and thus the contents of a given volume of sea water are known. The catch is next preserved in some suitable medium, such as *formalin* or *spirits*, and then it is subsequently estimated in the laboratory. There are four chief methods of estimating the contents of the catch—by *volume*, by *weight*, by *chemical analysis*, and by *enumeration*. For the latter, a special form of microscope is used, having a large mechanical stage, which by means of two screws can be rotated in any given direction. The stage is ruled with fine lines cut by means of a diamond, and these lines divide the stage into squares. Consequently, it is a simple though tedious matter to enumerate the constituents of a given column of plankton.

Important results have been deduced from this method of enumeration, more especially with regard to the floating fish-eggs. Take, for instance, the Eckenförde fishery in the West Baltic. This fishery for cod and plaice is carried on over an area of about 16 sq. miles, and there are on an average in January, 30; in February, from 45 to 50; in March, at least 60; and in April, 50 floating eggs of cod and plaice for every square metre of surface (a square metre equals 1·196 sq. yd.). These eggs take on the average about fifteen days to develop under the conditions which obtain in the West Baltic, so that the numbers above recorded must be doubled in order to give the number occurring per month under the square metre of surface water. This gives 370 eggs from January to April.

Determination of Intensity of Fishing. Now, it has been calculated from a nine-year average that the number of cod and plaice annually caught by the fishermen of this district would, if allowed to remain in the sea, have produced 110·5 eggs per square metre of surface water. This, added to the 370 above, gives a total of 480·6, which represents the number of eggs that would have been produced from all cod and plaice, captured and free yearly for each square metre of surface water. As a consequence, $\frac{110{\cdot}6}{480{\cdot}6} = \frac{1}{4{\cdot}4}$ gives the fraction of the total quantity of adult cod and plaice actually captured, or, in other words, man captures for his own consumption about one-fourth of the total number of adult fish in this locality in the West Baltic. This estimation has been confirmed in a remarkable manner by the marked-fish experiments which are now being carried on in the North and Irish Seas.

Marked Fish Experiments. Plaice are marked [12] with a numbered brass label attached to their bodies by a silver wire and then liberated. The active co-operation the fishermen is secured by means of a system of payment of rewards for marked fish returned to the laboratory, with information as to date and place of capture. A large number of such fish marked have been returned to the laboratories at Lowestoft and Liverpool, and it has been calculated that trawl fishing in the southern part of the North Sea has caused an appreciable reduction in the numbers of the larger plaice of 10 in. in length and upwards, this reduction amounting to from 20 to 30 per cent. of the total population of this size in one year. This corresponds very closely with the estimate of 25 per

cent. derived years ago by the study of the plankton along quantitative lines.

Other results from fish-marking experiments may be briefly mentioned here. The extent and nature of the migration of plaice is one of the chief results to be noted. In the southern part of the North Sea, plaice migrate from the inshore to the offshore grounds, in spring and summer months the general direction being a northerly one. Larger fish move quicker and farther than smaller ones. It is perhaps rather dangerous to attempt generalisations of too broad a nature, based as they are at present on rather insufficient evidence, but there seems to be a winter migration of all plaice above 9 in. in length towards the south.

Practical Bearings of Migration. Young flat-fish live, as is well known, for the most part, in shallow inshore waters, called *nurseries*, and some of the largest North Sea nurseries are those off the Dutch coast. The facts as to the summer migration tend to show that the English plaice fisheries to some extent depend for their supplies on these inshore grounds. On the West Coast certain nurseries are closed to all kinds of trawling on account of the large proportion of undersized fish met with; there is a closed area off Blackpool, for instance. In the Irish Sea from 30 to 40 per cent. of the marked plaice have been recaptured, though in some cases fishermen are reluctant to report marked fish captured by them. Off the Cumberland coast some of the inshore trawlers, believing the experiments had for their object the imposition of new restrictions, did not report marked plaice taken in their nets. A number of plaice were marked and liberated in Luce Bay, an area on the south coast of Scotland closed to all kinds of trawling by by-law of the Scottish Board. A sufficient number of these fish were recaptured on other grounds in the Irish Sea to prove that the waters of this bay serve as a preserve for mature fish which migrate offshore to spawn in the early spring, when the sea temperature in Luce Bay is much lower than on the offshore grounds.

Can the Sea be Depleted of Fish? One of the vexed questions of the sea fisheries of recent times is that of *over-fishing*. It would perhaps be more correct to say that the question of over-fishing has been with us for some considerable time, but that it has only recently become acute. The question can best, perhaps, be put in the following form: Can man, by his efforts, so upset the balance of Nature as to render further fishing unprofitable? That there must be some reason for supposing the answer to be in the affirmative would seem to be an obvious deduction from the numerous Acts of Parliament—and local by-laws passed in pursuance thereof—which have for their object the regulation of the sea fisheries. The various restrictive enactments which have for their object the protection of immature fish, or the prevention of destructive or wasteful methods of fishing, have all been passed as a result of the outcry against over-fishing and the alleged depletion of the sea. Restrictions as to the sizes and conditions under which fish may not be removed from a fishery, the regulation of implements of fishing, and the enactment of close times, all have resulted largely, but not entirely, as a consequence of the alleged vanishing of the harvest of the seas.

Statistical Evidence Accumulating If the deterioration of the fishing grounds is a fact, then one would naturally expect to find evidence of it in the statistical returns which have been furnished from year to year by the Government departments concerned. Unfortunately, there is reason to believe that the statistical evidence has not in the past been collected with sufficient care to render any results obtained from its analysis reliable; and it is only since the establishment of the international council that statistical evidence of the condition of the fishing grounds has gradually been accumulated. In addition to the customary record of the value and quantity of fish landed, what is known as *ichthyometric data* are collected. The market statistics are carefully analysed; samples of certain kinds of fish such as plaice and haddock are weighed and measured. Voluminous reports dealing with these statistics have been published from time to time. Those by Professor d'Arcy Thompson on the Aberdeen trawling statistics may be taken as a model.

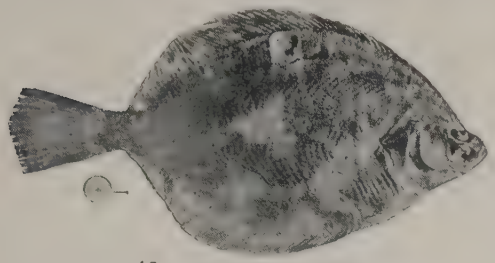
Professor Thompson deals at length with the sizes of plaice in the Aberdeen market, according to the various grades of market classification and for various localities. He shows, among other things, that the plaice from the near grounds off the East Coast of Scotland are smaller than those from any other grounds frequented by Aberdeen fishing-vessels, but are, nevertheless, considerably larger than the average size of plaice landed by English trawlers at the great English markets. The gradual decrease of plaice, both in the gross quantities landed at Aberdeen and in regard to the average catch per voyage and per hundred hours' fishing, is dealt with at some length. Finally, the increasing quantities of the so-called "extra small" plaice landed of recent years at Aberdeen are particularly dealt with. Professor Thompson is strongly of opinion that the destruction of these very small plaice is detrimental to the fishery, and that it yields no commensurate benefit to the trade.

It is impossible to deal here with the results of the enormous amount of statistical information which has been collected within the last few years, but, on the whole, and subject to certain exceptions, they show a steady if gradual depletion of the stock of some of our most valuable marine food-fish.

Fishing is Skilled Labour. Fishing is not unskilled labour. More is to be credited to the personal experience and local knowledge of the skipper than is generally supposed; and it by no means follows that a trawl shot at hazard in a given locality can be relied upon to give a fair average sample of the number of fish, even for a very limited area around that spot. Only extremely limited areas can be satisfactorily investigated by means of a steamer specially told off for the work. While there are undoubtedly many practical problems which can only be satisfactorily investigated from a specially equipped steamer—such as, for instance, the determination of the vitality of undersized fish caught in a trawl, or the relative destructiveness

to young fish of various-sized meshes—we would advise caution as to the acceptance of deductions as to over-fishing, based on evidence accumulated from one or even a few steamers. The only reliable method is the analysis of the commercial returns, supplemented by ichthyometric work on the trawlers and in the markets.

Collecting New Statistics. With the discovery of new fishing grounds off the Icelandic



12. A MARKED PLAICE
This fish was liberated off the River Mersey on Nov. 12th, 1904, and recaptured in the River Lune on Dec. 2nd, 1904.

coast, in the Bay of Biscay, and even so far distant as the White Sea and Morocco, there is no cause for surprise in the fact that the gross quantity of fish landed in the British Isles shows a continual and gradual increase. At the same time, the quantity of fish on and near the British territorial waters may be on the decrease, and evidence of fish caught in or adjacent to these waters is urgently needed. Steps have been taken by the Board of Agriculture and Fisheries and the Scottish Fishery Board for the careful and accurate record of the locality of origin as well as the port of landing for all sea fish, and, in addition, separate records of the fishing voyages of first-class fishing vessels are now kept There can be no shadow of doubt that this is an extremely valuable method of obtaining evidence of the condition of the fisheries.

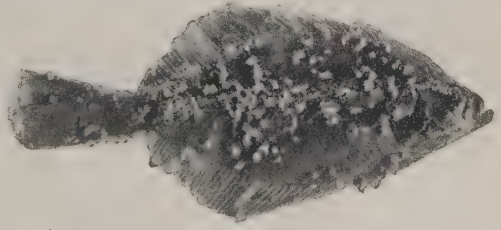
Protection of Immature Fish. In many methods of fishing, notably in *shrimping*, large numbers of undersized fish are caught, and in many instances these immature fish are unmarketable. Every haul with the shrimp-trawl in our inshore waters brings up, in addition to the shrimps, a number of small plaice, dabs, soles, herring, codling, and whiting, the number and species varying according to locality and season.

These fish are unmarketable, but if allowed to remain in the sea a proportion would presumably become of marketable size and be captured by the fisherman. If the shrimp trawls are hauled at short intervals and the net rapidly cleaned and the young fish promptly returned overboard, it is certain that a very large percentage of the flat fish would be uninjured, and they may be seen swimming away as soon as they are replaced in the water. With regard to the round fish, it may be said that they are far more susceptible to injury, and extremely prompt measures are requisite to secure that any reasonable proportion be returned to the sea alive. There can therefore be no reasonable doubt that many millions of undersized fish are captured by shrimpers in their trawl-nets, push-nets, and shanks; and formerly a very large proportion of these were destroyed. The process of separating the shrimps from the fish and other débris caught in a trawl is accomplished by *riddling;* and where such riddling is promptly done, and the débris and fish returned overboard immediately, little harm is done. Of course, the shrimper naturally selects ground where shrimps are most abundant, and the young fish are caught accidentally; and in this respect the shrimper differs from the whitebait fisherman, who intends to capture undersized fish for which he readily finds a market.

How to Stop the Needless Destruction of Fish. Where there is a market for undersized or immature fish, though it might be advisable to have the fishery carried on within reasonable limits, since obviously a certain proportion of adults must survive to propagate their kind, it would be as absurd to prevent it altogether as it would be to stop the sale of veal or lamb.

But in cases where the fish are caught accidentally or sold for manure or needlessly destroyed, prompt measures are necessary for the maintenance of the fishery; and where destruction is of a gratuitous nature there can obviously be no sympathy with the person responsible for the damage, though at the same time, where he is carrying on a bona-fide business, it becomes necessary to interfere with him as little as possible.

The most practicable method of dealing with a problem of this kind is to interfere as little as possible with the implements of fishing, but to see that they are not needlessly destructive, and in any case to see that they are used in a proper manner. The prevention of landing of fish under a certain size might stop the fishing *for* undersized fish, as distinguished from shrimping, where the undersized fish are accidentally present. But in many cases, on grounds frequented by undersized fish, there is a certain proportion above the legal minimum, and it still might be profitable to fish these grounds, throwing overboard the small fish. Most of these small fish would be killed and no advantage would accrue. Various enactments have been proposed for dealing with his evil, which is admittedly serious. Bill after Bill has been introduced into successive Parliaments, but, not being party measures, they have had no chance of being passed. But in the territorial waters local regulations, confirmed by the central authority (the Board of Agriculture and Fisheries), have dealt with and, to some extent, undoubtedly checked this wholesale and wasteful destruction. The establishment of reserve areas, either within or outside the territorial waters, where spawning or



13. FLOUNDER ATTACKED BY A SPOROZOAN PARASITE

immature fish are known to congregate, would be the most effectual means of preserving a continuity of our fish supply. But whether such an arrangement is within the sphere of practical politics is another question.

Artifical Hatching and Rearing of Marine Food-fishes. A certain section of scientific experts, being firmly convinced that a depletion of the seas was in operation, suggested

that man might, by artificial hatching and rearing of the fry of economic fish, restore the balance of Nature. The initiative with regard to the erection and equipment of marine hatcheries is due to the United States authorities, who regarded this plan as more suitable than attempting to prevent the destruction of immature fish by restrictive legislation—an alternative method which had been suggested as a remedy for over-fishing and its evil consequences. The whole method of working of the marine pisciculturist is, we believe, based on fallacious reasoning. But this is not the place to enter into destructive criticism of his efforts; we are merely content to describe what is claimed to have been done.

1500 Million Fish Hatched. The United States Fish Commission annually hatch and liberate about 1,500,000,000 fish fry, the principal salt-water fish dealt with being cod, flounders, and lobsters. The Canadian hatcheries deal mainly with cod and lobsters. The European countries which have adopted artificial hatching are Norway, Scotland, and England. The methods in vogue for obtaining fish eggs vary in the different establishments, but in England the mature fish are obtained by trawling from a special steamer some months before the spawning season begins. These fish are kept in tanks or open-air ponds attached to the hatcheries, and are claimed to constitute a reserve of spawners. The eggs are artificially fertilised, and then placed in the hatching-boxes, there to undergo their incubation.

The hatching-boxes are kept in constant motion by an automatic arrangement, and a current of sea water is maintained through the boxes. This serves the double purpose of oxygenating the eggs and preventing their settling. Up to the present no successful attempts have been made to rear the fish, the fry being set free a few days after hatching, or never later than after the absorption of the yolk-sac. These larvæ are (or should be) liberated on the off-shore spawning grounds, their natural habitat. No satisfactory evidence has yet been adduced that sea-fish hatching is an economical success. Originally it was doubtless worth an extended trial, but until rearing the fish as well as hatching them has been accomplished, opinion must be reserved as to the efficacy of this method of replenishing the sea.

Fish Diseases and Parasites. Fish, like other animals, are subject to "the ills that flesh is heir to," but the alarmist statements that have of recent years appeared in the public Press are quite without foundation, and it may once for all be said that no article of diet can be regarded as so absolutely free from disease as sea fish. The complaints from which fish suffer may be grouped under two headings—firstly, the attacks of parasites, either attached to the body externally (*ectoparasites*), or dwelling in the inside of the fish's body (*endoparasites*); and secondly, infectious diseases due to the presence of vegetable organisms (*bacteria*) or animal organisms (*sporozoa*). Of course, both bacteria and sporozoa are, strictly speaking, endoparasites.

The important question as to how far, if at all, the communicability of diseases from fish to man or vice versa is possible merits a brief notice. It is obvious that this question of the purity of fish as a food supply has the most important practical bearings, and the "scare" with regard to the connection of oysters and typhoid is a case in point. That shellfish may, under certain circumstances, be the means of communicating such a disease as enteric or typhoid fever to human beings seems to be well established, and not only oysters, but mussels and—though less certainly—cockles may occasionally be held responsible. This is, however, never due to the fact that the oyster is itself "suffering" from the complaint, but rather that the typhoid bacillus is accidentally present either in the food of the oyster or in the sea water enclosed in the shell. Modern research tends to prove that if reasonable care be taken in the selection of the site for bedding oysters, and if ordinary cleanliness be secured in the handling and preparing of the bivalve for the market, the risk of pollution is infinitesimal, and certainly not greater than is the case in many other articles of consumption, notably milk. The danger is reduced to vanishing point if the shellfish be thoroughly cooked.

Fish and Human Diseases. Within the last few years considerable attention has been devoted to the study of the diseases of fish, and a review of the literature devoted to the subject is rather a source of satisfaction than dismay. The diseases such as smallpox, phthisis, and dropsy which have been popularly attributed to fish disappear or become something quite different on closer inspection.

Fish, however, are undoubtedly attacked by such parasites as threadworms, tapeworms, and leeches. The worms are generally found in the intestines, and are removed with them. Leeches are rare, and drop off when the fish are caught. Certain crustacea (parasitic copepoda) attack fish, and are found attached to the gills, fins, eyes, and even in the nostrils. They, however, in most cases, only cause a temporary inconvenience. There remain, then, a few diseases attributable either to bacteria or sporozoa. An instance of the former is the well-known *salmon disease*, which was formerly thought to be due to a fungus (*saprolegnia*). An instance of the latter is shown in the figure of the flounder [13]. In all cases where a fish suffers from complaints of this kind, the body is unsightly, being marked with blotches or swellings which would immediately cause it to be rejected for food. In conclusion, though isolated instances of fish (chiefly fresh-water species) suffering from disease are from time to time recorded, in no case is the disease identical with any human complaint, and in every case spots or swellings are visible which would render the fish unmarketable. Nothing is said about unwholesome fish where the deterioration is due to the fish having been kept too long Naturally, fish, like all other perishable articles, require to be eaten in as fresh a condition as possible.

Preparation of Fish for the Market. Fish, if not speedily placed on the market, deteriorates rapidly, and hence we find a large number of methods of preservation. All these methods depend for the efficacy upon the necessity of eliminating the action of the bacteria responsible for the putrefactive changes which so rapidly take place. A second and most essential purpose to be borne in mind is the preparation of an article which shall at the same time be palatable and be capable of retailing at a reasonable price. The methods of preserving fish fall under four main heads—namely, by *ice*, *salt*, *smoke*, or *canning*. It must be understood that these methods are not absolutely distinct; a fish may, in the course of preparation for market, go through two or more of these methods in succession. A description of the multitudinous

modes of manipulating the raw material would fill the pages of a considerable volume, and therefore the only accounts given here are those which are practicable on a small scale. *Canning*, which requires special plant and is quite distinct from fishing proper, is not touched upon.

The "Finnan Haddies." There are, broadly speaking, three essential stages in the preparation of "finnans." These are splitting, salting, and smoking. The operation of *splitting*, to be rapidly and efficiently performed, requires actual practice. The head is removed, the fish split down the back, and eviscerated. It is then *salted* for about half an hour in strong brine, then drained, and afterwards smoked. The smoking is now carried on in small houses built for the purpose, the fish being spread open and suspended in tiers. The fuel used is peat, and the operation is continued without interruption for from four to six hours, during which period the fish requires constant attention. The fish are generally put up in boxes of the average weight of 40 lb. The barrels are about four times as heavy. For export purposes "finnans" are *canned*, but as these fish must be cooked, or at least boiled, before canning, in addition to the processes above described, it seems a misnomer to call them "finnans."

In addition to finnans there are other varieties of prepared haddocks, notably "smokies," where the fish are smoked over a hot fire, with abundance of smoke, until they have taken a golden colour; and "pale smoked haddocks," where the fish are but slightly smoked for immediate consumption.

The Preservation of Herring. The four chief methods of preserving herring are best enumerated under the headings by which the resulting product is known to the public—namely, *pickled herring*, *kippers*, *bloaters*, and *reds*. The *bloater* is intended for immediate consumption, and may be described as a round or unsplit herring which has only been slightly salted and smoked. The fish, as soon as possible after capture, are dry-salted for from six to twenty-four hours—the time being longer if the fish be fat—and afterwards smoked. The *red* is generally prepared for foreign consumption, and large quantities are exported to the Mediterranean. For this trade the herrings are salted in brine for about two days, and then smoked for a fortnight. The wood and sawdust used is of the "hard" variety, and from this the peculiar flavour of the red is derived. The red may be defined as a round herring, heavily salted, and smoked for a long time. They are packed chiefly in barrels and half-barrels, the former containing from about 500 to 600 fish.

Kippers and Pickled Herrings. *Kippers* are first of all split and eviscerated, then salted in strong brine for from a quarter of an hour to an hour, then spread out and smoked over hardwood shavings. The time for smoking varies, being longer at Yarmouth than at Aberdeen. *Pickled herrings* are more numerous than all the other varieties put together. These fish have their gills and intestines removed. They are then brine-salted and packed in barrels and half-barrels. In Scotland these herrings may be tested by the Fishery Board. If the merchant desires a certificate of the quality of the fish in his barrels, an officer of the Board opens and examines samples of these barrels, and if the contents come up to the required standard a brand is burned into the head of the barrel. A barrel generally contains 300 lb. of herrings, and each barrel is packed with great care, with alternate layers of fish and salt.

Fish Markets. Broadly speaking, the marketing of fish is left to a special class of individuals —fish auctioneers and salesmen. Even fresh fish is rarely disposed of by the fisherman himself, and the bulk of preserved fish and fish products he never sees. There are, of course, certain exceptions, such as potted shrimps.

Fish that is landed at any of the larger fishing ports, such as Hull, Grimsby, Billingsgate, or Aberdeen, is sold by auction on the quay. The fish is sorted into baskets or other receptacles, or may even be spread out on the quay floor as at Aberdeen, and the sale is invariably held by auction at an early hour in the morning.

Even fish that is landed by smaller boats at the quieter fishing ports is, to a very large extent, sent to large centres to be disposed of by auction, some occasionally even returning over the same ground for local consumption. The marketing of fresh fish is now such a special occupation that there is a considerable amount of truth in the complaint of visitors to seaside resorts, like Llandudno or Tenby, that they have to wait for the train from Grimsby before they can procure any fresh fish. Many markets for preserved fish are met with abroad, pickled herrings being an especial favourite with the Latin nations.

Oyster Culture. On the Continent *oyster culture* forms a considerable industry, absorbing a large amount of capital and affording employment to thousands of people; but in England, for various reasons, this industry has not been developed to the same extent. The success of oyster culture depends to some extent, as for instance at Arcachon, on the natural physical advantages of the locality. At Arcachon there is a large inland sea of about 30,000 acres area, which communicates with the sea by means of a narrow entrance, through which the tide ebbs and flows. In this lake the oyster reproduces itself naturally. The young stage of the oyster, known as the *fry* or *spat*, is of microscopic size, and swims about in the water for a time, and eventually settles down on suitable objects, there to develop into an adult oyster. [See NATURAL HISTORY, pages 3227-29.]

Spatting. The success of oyster culture depends upon the simple fact that the spat can easily be collected upon suitable objects. The oyster reproduces itself in spring or early summer, and the free-swimming stage lasts for about a week. At the time settling-down process begins, receptacles or collectors are placed in position. The Romans used bundles of twigs; the Dutch use earthenware tiles; in France the collectors are crates of similar tiles coated with a cement of lime and sand, which offer a convenient adhesive medium for the *spat*. The tiles are arranged in rows inside large cases, and in Arcachon alone about 12,000,000 tiles are annually laid down for this purpose. The spat is left on the tiles until the following October, when the young oysters are about the size of a finger-nail, at which stage they are known as *seed oysters*.

Rearing and Greening. They are now removed from the tiles and are taken in hand by the "éleveurs," who rear and fatten them to a marketable size. This is done by arranging the *seed* on flat trays of galvanised wire netting, which are placed in shallow oyster "parcs" in which the tide circulates. Great care is taken with the rearing process, the oysters being constantly looked after by men and women, who inspect the trays at low water and remove impurities and enemies, such as starfish. Thinning out is soon necessary,

the growing oyster being removed to other trays or transferred to the floor of the "parc," which is often suitably prepared for their reception.

The process of *greening* is undertaken at Marennes, where the oysters are kept in muddy salt-ponds, in which they gradually become green, owing to the presence of a particular diatom in their food, and acquire a peculiar, delicate flavour.

Board of Trade Certificates for Fishermen. According to the provisions of the Merchant Shipping Act, 1894, no trawler of 25 tons or upwards shall go to sea from any port in the United Kingdom unless there is on board a duly certificated skipper and second hand. By an order of the Board of Trade the requirements of the Merchant Shipping Acts in regard to the certification of skippers and second hands is extended from July 1, 1910, to all liners and drifters of 50 tons gross tonnage and upwards which are propelled by steam or other mechanical power.

Every fisherman with a spark of ambition will be interested to hear particulars of the certificates issued and the best way to set about obtaining one. The Board of Trade examines candidates for certificates of competency, and there are three different certificates to be obtained by any deep-sea fisherman who is prepared to sacrifice a little of his leisure. These certificates are for second hands, skippers, and extra skippers.

A Second Hand's "Ticket." To obtain the certificate which is issued to *second hands* who fulfil the necessary conditions and pass the required examination, several preliminary qualifications are requisite. The candidate must not be less than nineteen years of age, he must have served at least four years at sea, of which two years must have been on board a deep-sea fishing boat. If he has served his time, the candidate should apply to the nearest Mercantile Marine Office for a form of application (s. 20), and he must take care to fill this form up properly. When the form is returned to the office the candidate must attach to it his testimonials of general good character, and of sobriety, experience, ability, and good conduct on board ship. A fee of 1s. is charged for the examination. The candidate will be examined as to his vision, and, in addition, the rule of the road at sea, the marks on the lead-line and the use of the lead, taking bearings by compass, ability to use a chart, and generally as to the duties of a second hand. The candidate must have a good knowledge of all the articles of the regulations for preventing collisions at sea. Questions regarding the rules of the road at sea are illustrated by means of models of vessels; and various coloured balls, representing lights, are used to represent vessels at night. Mates or second hands are also tested as to their abilities in reading, writing, and arithmetic.

A Skipper's "Ticket." Candidates for certificates as *skippers* must have served five years at sea, of which one year must have been as certificated second hand on board trawlers of 25 tons tonnage and upwards, or as second, third, or fourth hand of a steam or sailing liner or drifter of similar tonnage. An applicant for a certificate as skipper must be not less than twenty-one years of age. In addition to the subjects enumerated for second hands, skippers are required to be acquainted with general duties required for skippers, such as getting under way, what to do when the engines are broken down, or when the vessel has sprung a leak, or when the rudder has gone, or on the use of a floating anchor. They are also required to make themselves acquainted with their civil duties under the Merchant Shipping Act of 1894; for instance, as to the returns of the list of crew, or as to agreements or apprentices' indentures. For extra certificates the applicant must show a knowledge of the use of the quadrant, and be able to take observations, to read on and off the arc, to find the index error by the horizon, and to determine the latitude by the meridian altitude of the sun.

Signalling and Compass Deviation. Voluntary examinations in signalling and compass deviation are also open, without fee, to all fishermen holding or who have passed for a certificate of competency as second hand or skipper of a fishing vessel. If the candidate be successful, the fact, with the date and place of passing, will be recorded on his certificate. Candidates may be examined at any port where examinations of masters and mates or special examinations of fishermen are held, on making application on Form Exn. 2. Various County Councils and other local education authorities have now instituted classes in subjects for certificates for management of fishing boats; and as a good deal of the instruction is of a practical nature, and cannot be learnt from a book, the candidate is advised to make local inquiries as to such classes.

Sea Fishery Law. The history of the legislation applied to the fisheries does not afford the student very pleasant reading. All the older and some of the more recent legislative efforts of Parliament were based on a profound ignorance of the technique of the fisherman's craft. We are, however, not so much concerned with what the legislation has been as to what it is now, and along what lines its future development may be expected. The words of Professor Huxley (inaugural address, Fisheries Exhibition, 1883) have lost none of their force at the present day; and as they embody the maxims or axioms which are fundamental, they may well be reproduced here:

"Every legislative restriction means the creation of a new offence. In the case of fishery, it means that a simple man of the people, earning a scanty livelihood by hard toil, shall be liable to fine and imprisonment for doing that which he and his father before him have, up to that time, been free to do. If the general interest clearly requires that this burden should be put upon the fishermen—well and good. But if it does not—if, indeed, there is any doubt about the matter—I think that the man who made the unnecessary law deserves a heavier punishment than the man who breaks it."

The Necessity for Knowing Fishery Law. At the present day, when considerable capital is devoted to the building and equipment of large and powerful vessels which fish to some extent near the territorial waters of foreign countries in addition to the waters of England, Scotland, and Ireland, the skipper of such a boat has to be acquainted with a not inconsiderable body of legislative enactments, which are here briefly summarised.

In the first place, the whole part of Part IV. of the Merchant Shipping Act of 1894 deals with fishing boats; but as the skipper of every English trawler over 25 tons tonnage undergoes an examination as to his knowledge of this section of the Act before he obtains his captain's certificate, it will be unnecessary to do more than point out the main features of the Act. All fishing boats are (or should be) conspicuously numbered and lettered, and when fishing at night should carry certain lights, the details being given in the Act.

Other regulations relate to the fishing boat's register, to discipline, to apprentices, and agreements with seamen. This Act, of course, applies to British fishing boats even outside British territorial waters. Other regulations for fishing may be divided into two groups: (1) Those which are enforced on the high seas, or beyond the territorial limits. (2) Those which are enforced only within British waters.

Regulations in Territorial Waters. There are three Acts, and a Convention between Britain and Denmark, which define the territorial waters within which His Majesty's subjects have the exclusive rights of fishing. The Convention Act of 1843 defines certain waters which are to be reserved for French and English fishermen in their respective countries, and here, in addition to three geographical miles from low-water mark, we find bays, the mouths of which do not exceed ten geographical miles in width, also reserved, and the limit is to be reckoned as being distant three miles to the seaward of a straight line drawn from low-water mark off one headland to low-water mark off the other headland of such bay respectively. By a subsequent Act of 1868, which, like the Act of 1843, was intended to carry out a Convention between England and France, we find a similar definition, except that the straight line across the bay is to be drawn from "headland to headland," no mention being made of low-water mark. This convention was never carried out by France, the necessary legislation to make it operative never having been passed. A later Act (of 1883) defines exclusive rights of fishery as regards bays, and states that the distance of three miles shall be measured from a straight line drawn across the bay in the part nearest the entrance at the first point where the width does not exceed ten miles. This Act carries out a convention between England, Germany, Belgium, Denmark, and Holland. No definition of a "bay" is given, but presumably any indentation of the coast line is a "bay" within the meaning of the Act. In the Anglo-Danish Convention of 1901, the distance may be measured not only from low water of the coast, but also from dependent islets, rocks, and banks.

It must not be assumed that the exact delimitation of the territorial waters is a point of merely theoretical importance. Some of the laws restricting steam trawling in foreign territorial waters are very stringent. For instant, trawl fishing within the territorial waters of Iceland or the Faroes is punishable by a fine not exceeding 4000 kroner (£220), together with forfeiture of all the fishing gear, including the drag ropes. That heavy fines are not infrequently inflicted English skippers know to their cost. Even to enter Icelandic or Faroe waters with a trawl on board not stowed away, is punishable by a fine of 2000 kroner, and the ship, catch, and fishing gear may in either of these cases be seized and sold to cover the legal expenses.

Regulations for Home Waters. Apart from the question of *territorial waters*, which are reserved to native fishermen, we have to deal with restrictions applied in the British Islands, and at the outset a fundamental difference is to be noted. For England and Wales, although the Board of Agriculture and Fisheries is the central authority for sea fisheries, the by-laws regulating the industry are formulated and administered by local Sea Fisheries Committees, which were called into existence by the Sea Fisheries Regulation Act, 1888. Although these by-laws are formulated by the committees they need the sanction of the central authority before they become operative. In Scotland and Ireland, on the other hand, the administration of by-laws is controlled by a central authority, and this distinction is accompanied by an extension of the area under control, for whereas in England and Wales by-laws only apply to the territorial waters, in both Scotland and Ireland the jurisdiction of the central authority extends beyond this. Naturally this extra-territorial authority can only be enforced against British subjects—at any rate while their vessels fly the British flag.

In Scotland trawling is absolutely forbidden in territorial waters (the Herring Fishery [Scotland] Act, 1889); it is also forbidden in certain Scottish waters outside the three-mile limit, notably in the Moray Firth and the Firth of Clyde.

In Ireland no extensive advantage has been taken of Section 3 (1) of the Steam Trawling (Ireland) Act of 1889, which allows the inspectors of Irish Fisheries to prohibit "beam-trawling or other trawling within three miles of low-water mark of any part of the coast of Ireland, *or within the waters of any other defined areas* specified in any such by-laws, and subject to any conditions or regulations contained in such by-laws." There are, however, certain extra-territorial waters closed under by-laws made in pursuance of this section, notably off the coast of Waterford.

By the Trawling in Prohibited Areas Prevention Act, 1909, no fishing vessel, foreign or British, may land or sell or attempt to land or sell any fish in the United Kingdom if such vessel within two months previously shall have been employed in either trawling or taking fish on board within any of the prohibited areas of the sea adjoining Scotland or Ireland.

Fishing Grounds at Home and Abroad. In England, trawling from steam vessels is practically prohibited within three miles from the shore; trawling from sailing vessels is only allowed with nets the meshes of which are a certain size, and there are in various localities regulations as to the tonnage of sailing trawlers. Certain grounds are closed to all kinds of fishing but lining. There is at present no regulation as to the size at which *sea fish* may be landed or exposed for sale, but such regulations are in force for shellfish.

Shellfish are frequently protected by closed seasons, and berried lobsters and crabs may not be removed from a fishery. Broadly speaking, the local fisheries committees absolutely prohibit wasteful and destructive methods of fishing. The powers of district committees are extensive with regard to prevention of certain methods of fishing, or the regulation of fishing implements, but do not extend to imposing a size limit for sea fish.

Steam trawler skippers who fish in the vicinity of foreign waters have to be careful. As a rule, the fines inflicted are excessive, being far above the modest £20 which is the maximum "penalty" in England and Wales; moreover, either to be in foreign waters with implements of fishing on board not stowed away or with the *intention* of fishing is in some cases punishable. That this regulation may at times be pushed to, or even beyond, its logical limits is evidenced by a decision of the German Appeal Court, at Leipsic, which decided in the case of the smack "Lady Godiva" that the presence of a foreign fishing boat in German waters with the *intention* of fishing was an offence equivalent to that of actual fishing.

General Drawings. Detail Drawings. Frames for Vertical and Horizontal Engines. Machine Tool Frames. Crane Frames. Engine Details.

MACHINE DESIGN

General Drawings. Figure 128 is a *general arrangement drawing*, made after the details have been worked out on separate sheets, and it serves as a guide for the complete assembly and erection of the machine. The foundation blocks are fully dimensioned in the side elevation, and the holding-down bolts are shown in position. The small plan view gives the relative position of the blocks. The two sleepers, A, A, connect the outer foundation blocks to the centre one located under the crane-mast; such a foundation is substantial and permanent. Very frequently, however, this type of crane has only temporary foundations, such as timber seatings and weights simply laid across the ends of the sleepers. The mast is furnished with top and bottom pivot pins, and the backstays support the top pivot. The crane gearing is seen in position at the lower end of the mast; there is a train of spur gear from the handle shaft, B, connecting to the barrel, C, which coils the hoisting-chain. A clutch, D, and gears, E, couple the hoisting barrel C to the barrel, F, upon which is coiled another chain, which varies the radius of the jib by altering the length of the ties, G, this movement being termed *derricking*, or *luffing*, the jib. The revolving or slewing gear is arranged behind the mast, and consists of spur and bevel gear, connecting to the curb ring, H, which is bolted to the bedplate underneath the mast.

Detail Drawings. The drawings from which machines are actually manufactured are termed *detail drawings*, each part of the machine being fully delineated and dimensioned upon one or more sheets. Castings have a sheet to themselves, forgings have a separate sheet, plating another, and so forth, the object being to provide each works department with drawings that concern the department alone. The principal detail drawing is the one which depicts the main framework of the machine. Framings are made of various metals and in various forms. Machine tools and engines are invariably built with cast-iron frames, although exceptions are to be found, the chief virtue in such frames being rigidity, a factor that cannot be calculated in anything like an exact manner.

Steam-hammer Frame. A *detail drawing* of a frame for a steam hammer is given in 129. The views presented comprise a side elevation, a back elevation, a plan of the top, two sections, and separate details of bosses. The head of the frame is arranged to receive a square bolt, which is cottared in place; the upper end of the bolt passes through the foot of the hammer cylinder, as well as the two outer bolts, and holds it down with a nut in the usual way; there are two such frames, one on each side of the hammer block. The section of the frame is what is termed H section instead of a hollow rectangle; the inner flange throughout is heavier than the outer one, it being subjected to severe compressive shocks; three cross ribs are arranged to tie the flanges together, and to stiffen the web plate. The taper allowed on the flanges is considerable, and large radii are put in the corners. This is done in order to ensure a sound casting, free from initial stress due to contraction, and also to enable the pattern to be drawn easily from the mould, and so produce a smooth outline. The front of the frame at the bottom of the hammer guides is specially heavy, to prevent fracture at this point. The bosses are for the pivot pins of the working levers. The base of the frame is provided with facing strips and bosses for the foundation bolts, and the holes are slotted so as to permit adjustment endwise. The slope of the upper part of the frame is obtained by prolonging the line, as shown [129], until it forms a tangent with the inside radius of the lower part. The drawing is reproduced from an actual working drawing supplied by Messrs. Thwaites Bros., of Bradford, Yorkshire.

Mild Steel Frames. Mild steel frames are not used for machine tools proper, on account of their elasticity and consequent lack of rigidity; they do, however, enter into the construction of many appliances used by engineers, and in such appliances have a far greater value than cast-iron frames. Locomotive frames, carriage frames, large crane frames, furnace charging machines, etc., are examples in which cast iron would be a failure. Fig. 130 illustrates the steel frame of an overhead traveller as used in most engineers' shops. It consists of a pair of girders, A and B, secured to two cradles, C and D, which are mounted upon double-flanged wheels. These wheels are set to run upon rails which are built on the side walls or columns of the shop. The girders A and B are provided with rails which form the track for a trolley or crab, which is fitted with hoisting mechanism and necessary tackle. The machine is driven electrically, a separate motor being applied to each movement. The example [130] is for a high-speed electric traveller, and it is therefore specially braced to meet the stresses due to inertia in starting and stopping. The auxiliary girders, E and F, are stayed to the main girders A and B by bracing bars on the lower boom, in such a way as to afford them lateral support; the upper booms have chequer plates connecting them, instead of bracing bars, and these incidentally form a platform for the attendant, and are protected by handrailing as shown at G. The distance from centre to centre of the main rails, H, is termed the span, and the distance apart centre to centre of the wheels, I, is the wheel base, and is usually one-fifth of the span. The depth of the main girders at the centre of the span is generally one-fifteenth of the span.

The upper elevation shows the main girder with its joints. The web plate is made in four lengths for convenience, while the boom plates and angles are made in two lengths; the central joint is shown in plan. The next elevation is of the outer girder with the handrailing on top, the form of the bracing being known as the Linville, and being economical of material. The general plan view shows all the girders in position, as well as the cradles and platform. The two bottom left-hand enlarged views are details of the cradles,

while the right-hand bottom view is an enlarged section cut through the four girders at the centre.

Calculations. The main sections of the various members of such frames as **128** and **130** can be decided by calculations. In **128** the load on the jib and tie may be determined as described on page 389 in this group. The tie-rods and chains are tension members, and can have sufficient area allowed to permit a factor of safety of 8 to 1; the jib is a column, and should have a factor of safety of 6 to 1. The load on the backstay is found by taking moments about I; the forward moment is made up of the load multiplied by the full radius plus the weight of the jib multiplied by half the radius; adding these two moments together and dividing the distance, J, we get the load on the backstay (B1). The backstay may be either in compression or tension, according to the position of the jib in plan; as it is weakest in compression it may be proportioned as a column with a factor of safety of 6 to 1. The load on the sleeper and the mast is easily obtained by a simple diagram. Mark off the load on the backstay as K L on a scale of tons, and draw a vertical line from K till it cuts a horizontal line from L, meeting at M, then K M scales the load on the mast, and L M scales the load on the sleeper. Both mast and sleeper have alternatively tensile and compressive loads in a similar manner to the backstay, and they are proportioned for compression; the mast has to sustain in addition the load due to the hoisting and derricking chains, which also impose compressive loads.

Travelling Frame. In **130** we have the simple case of loaded beams or girders, which has been fully dealt with on page 510. The load on the main girders is made up from the actual load lifted by the traveller plus the weight of the movable crab and half the weight of the girders themselves. The cradles may be regarded as beams oi a length equal to the wheel base, and loaded at the two points at which the main girders are built in; each cradle has to sustain half the weight of the whole framework plus nearly the whole weight of the crab and load; the exact amount of this latter sum depends upon the nearness of the extreme position of the crab to the cradle. The outer girders have to sustain their own weight and half the weight of the platform, etc. When long spans are involved, the main girders as well as the outer girders are often designed as Warren or Linville braced members.

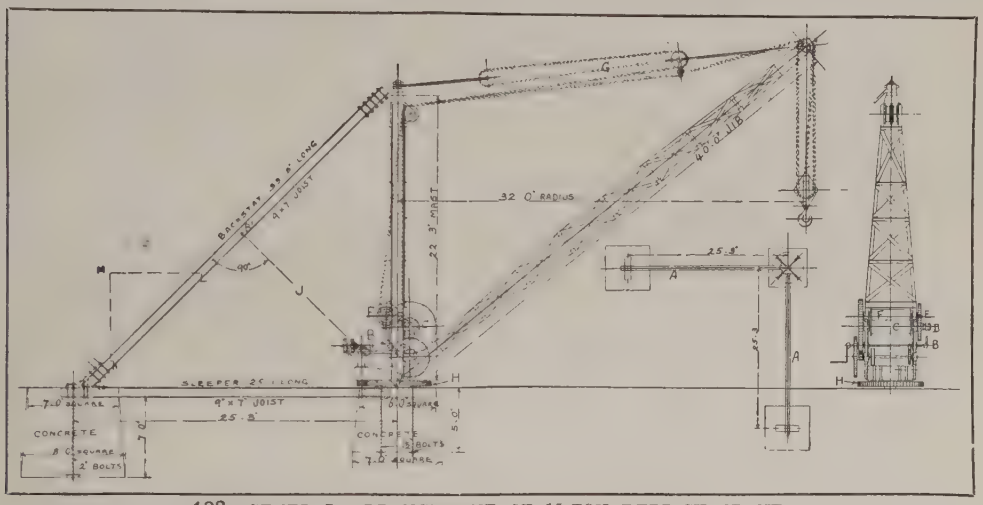
Cylinders. One of the principal *detail drawings* of an engine is that which represents a cylinder or cylinders. Fig. **131** shows a drawing of the high-pressure cylinder of a compound engine; the bore is 16 in. and the stroke of the piston is 36 in. The liner, A, is cast of harder metal than the cylinder body, and is forced into place by hydraulic pressure; the space, B, between the liner and the body is frequently used as a steam jacket—that is, live steam is admitted to the space in order to keep the temperature of the liner as uniform as possible. Small engines are not usually so made, but the cylinder body is simply bored out for the passage of the piston. The thickness of cylinder walls and liners is largely determined by practice; it is seldom less than $\frac{5}{8}$ in. for cylinders up to 10 in. bore; above 10 in. the following formula may be used:

$$T = \frac{D \times P}{3000}$$

where T = thickness required, D = diameter of cylinder, and P = steam pressure in pounds per square inch. It would not do to simply calculate the thickness necessary to withstand the bursting effort of the steam pressure; there must be sufficient metal to ensure rigidity and to stand re-boring after wear has taken place.

The cylinder ends and covers, C and D, are slightly thicker than the cylinder walls; the size and pitch of the studs or bolts which secure the cover affect its thickness to some extent. A good rule is to make the cover and the flange of the cylinder $1\frac{1}{4}$ times as thick as the cylinder itself, then the studs may be pitched $4\frac{1}{2}$ diameters apart for steam pressures up to 100 lb. per square inch, and $3\frac{1}{2}$ diameters apart up to 160 lb.

The diameter of the cover-studs is determined by calculating the load upon the cylinder cover, and apportioning sufficient area in the studs to meet the load; a safe stress is 3000 lb. per square inch of stud area. Care must be used in taking the area at the bottom of the thread. Studs

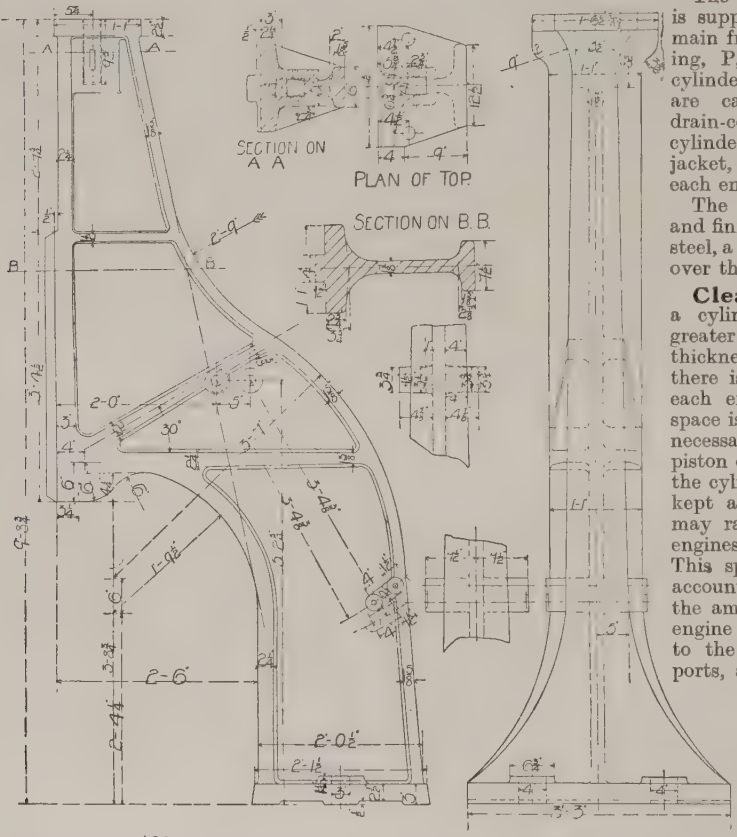


128. GENERAL ARRANGEMENT OF 15-TON DERRICK CRANE

smaller than $\frac{5}{8}$ in. diameter are not to be recommended for covers, as they are liable to damage in tightening up with an ordinary spanner. The covers of small cylinders are made with a single sheet of metal; for medium cylinders this sheet is strengthened with ribs, while for large cylinders the covers are made hollow with internal ribs.

The front cover, C, is cast with the cylinder, and has a stuffing-box, or gland, fitted for the piston-rod to work through.

The Valve-chest. The valve-chest forms part of the cylinder casting, is of sufficient size to accommodate the valves, and is provided with a



129. FRAME FOR A 25-CWT. STEAM HAMMER

cover, F, and stuffing-boxes, G and H; the box G is for the main-valve spindle, and the box H for the expansion-valve spindle. Steam-ports, U and K, are arranged from each end of the cylinder to the valve-chest; the ports L and M are for the exhaust steam.

The area of the steam-ports should be such that the steam does not flow at a greater velocity than 6000 ft. per minute, while the area of the exhaust port should allow a velocity of 4800 ft. per minute; the calculation is then:

Steam-port area

$$= \frac{\text{area of piston} \times \text{piston speed}}{6000};$$

exhaust port area

$$= \frac{\text{area of piston} \times \text{piston speed}}{4800}.$$

The length of the port—that is, the dimension measured at right angles to the length of the cylinder—is usually three-quarters of the cylinder diameter, and, this being settled, the width of the port is easily calculated from the area. The wider the port, the greater the travel of the valve, and it is sometimes necessary to make the port as long as the cylinder diameter in order to restrict the travel of the valve.

Steam is admitted to the valve-chest by the opening N, and exhaust steam leaves by the opening, O, both of these apertures having facings to which pipe-flanges connect.

The front end of the cylinder is supported by the end of the main frame casting; a foot casting, P, takes the weight of the cylinder to the foundation. Bosses are cast on for attaching a drain-cock at the end of the cylinder, a drain-cock for the jacket, and an indicator cock at each end.

The whole cylinder is lagged and finished off neatly with sheet steel, a dished casting being fitted over the back cover.

Clearance. The length of a cylinder is always slightly greater than the stroke plus the thickness of the piston—that is, there is a small space allowed at each end of the stroke. This space is termed *clearance*, and is necessary in order to prevent the piston coming into contact with the cylinder covers; it should be kept as small as possible, and may range from $\frac{5}{16}$ in. in small engines to $\frac{1}{2}$ in. in large ones. This space must be taken into account when calculating the the amount of steam used in an engine; the same remark applies to the capacity of the steam-ports, as these have also to be filled and emptied at each stroke. The total clearance space in an ordinary engine is usually from 3 per cent. to 6 per cent. of the actual volume swept by the piston in its stroke.

Piston. A piston is not quite such a simple article as would appear at first sight, and, as a matter of fact, there are scores of different types in existence. The simplest form is shown in **132**, and consists of a cast-iron body having three rings let into recesses; these rings are made slightly larger than the piston body, and are then cut through diagonally in one place; they are sprung into position on the piston and squeezed into the cylinder. The effort of the compressed rings is to expand constantly, and the resulting pressure on the walls of the cylinder makes the piston steam-tight. These are known as Ramsbottom rings, and are made of steel, but cast iron wears better. When made of the latter metal they should not be less than $\frac{3}{8}$ in. wide. Another form is shown in **133**, which presents a larger wearing surface than **132**. There are two rings, both of which are cut through

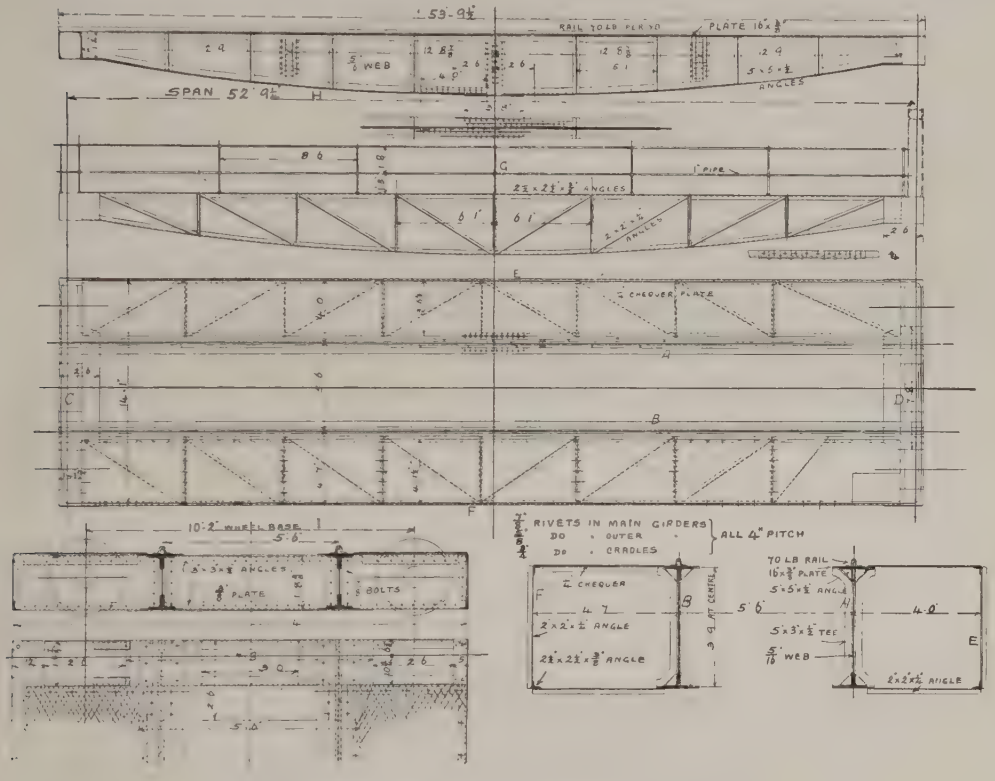
diagonally; a large spiral spring forces them outward to make them steam-tight against the cylinder. Such rings cannot be sprung into place, so the piston is made in two parts. The body, A, is a hollowed casting, as shown in **133**, and a loose ring, B, termed a *junk ring*, is secured to the piston body and serves to keep the rings in place. The depth of a piston may be from a quarter to half of the diameter of the piston.

The diameter of the piston-rod may be calculated by the use of the formula:

$$d = \cdot 013 \sqrt{DLP},$$

where d = diameter of rod,
D = diameter of cylinder,
L = length of rod in inches,
P = steam pressure in pounds per sq. in.

should have double guides. Looking at the diagram [**134**], and considering the engine to be running in the direction of the arrow, A, it is evident that both the piston-rod and connecting-rod are in a state of compression during the outward stroke; there is consequently a downward force acting on the crosshead, which is supported by the guide-bar. Now consider the return stroke, as shown in dotted lines. Here the piston-rod and connecting rod are in a state of tension, and consequently there is again a downward force on the crosshead. In fact, so long as an engine runs in one direction, the pressure on the guide-bar is always in the same sense. If the engine be reversed, then the direction of the force on the crosshead is reversed, and means must be provided to support



130. FRAME FOR A 35-TON ELECTRIC TRAVELLER

The attachment of the piston to the rod is usually made with a taper end and nut, as shown in **132**, but the taper is not absolutely necessary, for a parallel neck could be used and a shoulder or collar provided at the front end. A good taper is 1½ in. of diameter to 12 in. of length.

Crossheads. Crossheads are made in great variety; **136** shows a single slipper crosshead. The end of the piston-rod is swelled up to receive a half brass, and to accommodate the cap-bolts of the other half brass; provision is also made for bolting on the cast-iron slipper which runs between the guide-bars. The cap and rod are of mild steel, and the slipper is easily renewed when worn. Fig. **137** illustrates a heavier type of crosshead made with double slippers, to bear on double guide-bars; reversing engines it. The example given [**137**] is in general the same as **136**, but the slippers are larger, and are secured to the forging by studs and square keys as shown.

Adjustment for wear is made by means of wedges let through the keys; these wedges are moved by the nuts on their screwed ends; the main bolts have lock nuts similar to those in **36** on page 5405. Crossheads are also made to work in circular bored guides, the slippers being turned to suit.

Connecting-rods. Fig. **138** shows a connecting-rod of marine type suitable for working with the crosshead illustrated in **136**. The end is forked to embrace the crosshead, and the pin is kept from turning by means of a small stop-pin, as shown; the rod is circular, and is forged with a headpiece to take the gun-metal wearing-blocks. These blocks are divided at the centre, and are

held together with two bolts passing through them. An outer steel cap takes the bending movement due to the pull on the rod. The nuts on the bolts are similar to **36**, page 5405, but the steel cap receives the locking screw in place of a separate collar; in small engine work it is usual to use ordinary double nuts. Connecting-rods, like piston-rods, are subjected to alternate tensile and compressive loads. As they are weakest in compression, they are designed as struts or columns, but allowance must be made for the inertia of the rod itself, and this factor—especially in high-speed engines—makes the calculation quite a complicated one. The following empirical rule, due to Seaton, agrees closely with modern practice:

Diameter of connecting-rod in middle $= \frac{\sqrt{LK}}{4}$

where L = length of connecting-rod in inches
and $K = \cdot 03 \times \sqrt{\text{load on piston in pounds}}$.

The length of a connecting-rod is usually two and a half to three times the stroke of the piston. Figs. **139** and **140** show two other types of connecting-rod ends, both of which have solid ends and adjustable brasses. The former is adjustable by a cottar, and has a Babbitt lining; the flanges of the brasses are left off on the top and bottom on one side, so that the brasses may be put in place sideways. The example **140** is used for the crosshead end of the rod, in which case it enters a socket in the crosshead; it is adjustable by means of a wedge-block and nuts, as shown. The crankshaft end of a connecting rod is always termed the *large end*, and the opposite end, the crosshead end, is termed the *small end*.

Crankshafts. The Board of Trade rules for marine crankshafts are as follows:

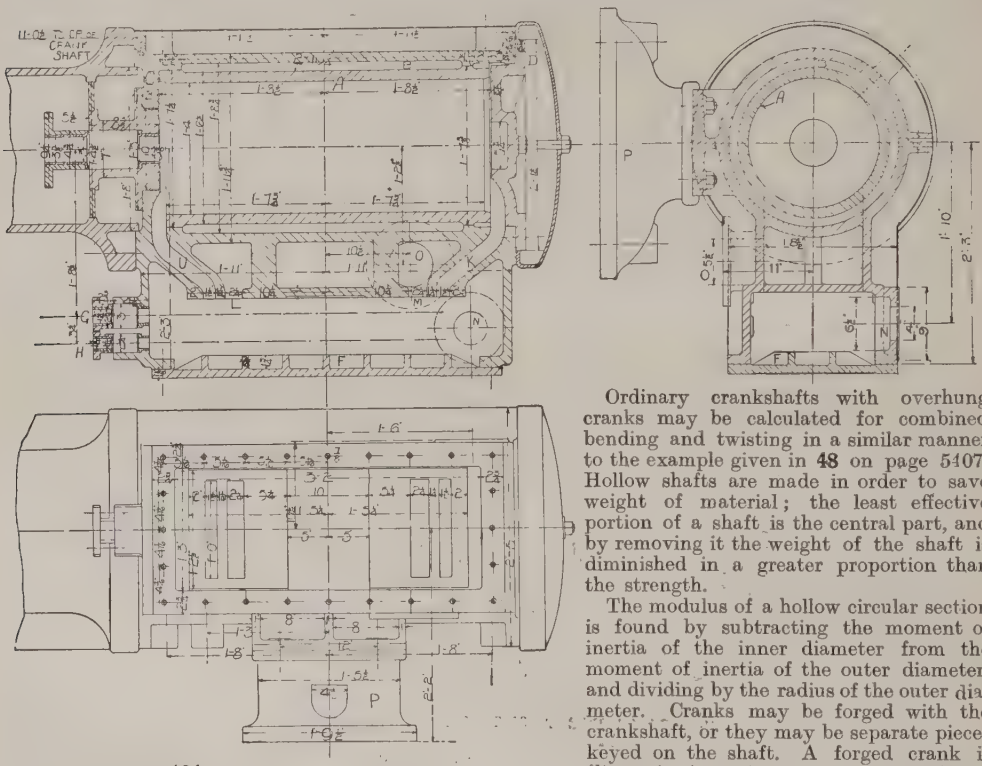
Let S = diameter of shaft in inches.
P = absolute boiler pressure.
C = length of crank in inches.
D = diameter of low-pressure cylinder.
d = diameter of high-pressure cylinder.
f = a factor depending upon angle of crank.

For compound condensing engines with cranks not overhung,

$$S = \sqrt[3]{\frac{C \times P \times D^2}{f\left(2 + \frac{D^2}{d^2}\right)}}$$

The values for f may be taken from this table.

Angle between cranks	90°	110°	120°	140°	160°	180°
Value for f ..	1047	904	855	788	751	740



131. ENGINE CYLINDER

Ordinary crankshafts with overhung cranks may be calculated for combined bending and twisting in a similar manner to the example given in **48** on page 5407. Hollow shafts are made in order to save weight of material; the least effective portion of a shaft is the central part, and by removing it the weight of the shaft is diminished in a greater proportion than the strength.

The modulus of a hollow circular section is found by subtracting the moment of inertia of the inner diameter from the moment of inertia of the outer diameter, and dividing by the radius of the outer diameter. Cranks may be forged with the crankshaft, or they may be separate pieces keyed on the shaft. A forged crank is shown in **135**; it is generally machined all over, and the ends turned in the lathe about the centre, A. The diameter of the pin, B, is usually the same diameter as the shaft; the width, C, is one and a quarter times the shaft diameter, and the thickness, D, is three-quarter times the shaft diameter. The cranks and pin may be separate pieces, in which case the cranks are swelled out to fit over the shaft and over the pin; the thickness of metal allowed in the swelled parts should not be less than ·4 of the shaft diameter.

Cast-iron crank discs are made as **142**, the crank-pin is fitted in tightly, and the end riveted over; the metal is thickened up at the side opposite the pin for the purpose of balancing the connecting rod head.

Main Bearings. An example of an engine main bearing is given in **141**. The brass is in four parts, so as to permit adjustment all round the shaft. The top and bottom parts are adjusted in the usual way, but the side portions are set up by means of a taper block and screws, as shown; the drawing explains itself.

Flywheels. The theory of flywheels is discussed on page 2358 in this group. Fig. **145** shows an ordinary flywheel; the rim is solid and is arranged with pockets round the periphery; these pockets are used for starting the wheel from rest when the engine is on dead points. The appliance which effects the starting is termed a *barring gear*, and may range from a simple lever to a separate small engine. The arms of the wheel are oval, and they taper from the boss to the rim. The boss has wrought-iron rings shrunk on to give it increased strength.

A smaller flywheel is shown in **143**; the arms are rectangular in section, and cranks are cast with the boss; such a wheel would be used on a small pumping engine. The inside of the rim opposite the crank-pin is thickened up to balance the pump-rod head.

Eccentrics. Eccentrics are used to give reciprocating motion to the valve-rods on an engine; a common example is shown in **144**. The inner part, or sheave, A, is keyed to the shaft; the centre of the sheave does not coincide with the centre of the shaft; the distance apart, B, of the centres represents half a stroke of the strap, C, and the eccentric rod is bolted up to the end, D. Both strap and sheave are in halves for convenience of renewal, but the sheave is not always in halves; the straps must be made so on account of getting over the register, which keeps it sideways.

Valves. A simple D valve is shown in various positions of stroke in **147** to **150**; the stroke of the valve is due to the eccentric. In **147** the valve is just open to steam, the piston is at the beginning of its stroke, and the connecting rod and crank are in a horizontal line—that is, on dead centres. The exhaust port is nearly full open. In **148** the valve is full open to both exhaust and steam, the piston is is travelling along the cylinder, and the crank at 45°.

In **149** the valve is reversed by the eccentric, and has closed the steam-port, the piston is moving forward under the influence of the expanding steam, and the exhaust is partially closed; the crank is well over 90 deg. In **150** the exhaust is closed, and the valve is moving to open steam for the reversal of the piston stroke. There are many types of valves in use, but their duties are all identical—namely, to regulate the flow of steam and exhaust to and from the cylinder economically.

Pumps. An air-pump, together with two bilge-pumps, is shown in **146**. The air-pump is of brass, though not necessarily so, and the thickness of its walls is kept down to a minimum, as the metal is expensive. The piston is termed a *bucket*, and is fitted with non-return valves for lifting water; the top and bottom of the pump are fitted with separate plates carrying similar valves. The bilge-pumps are of heavier metal, as they have to pump against a head; they are used for pumping the bilge-water from steamships. The plunger displaces a volume of water equal to its bulk at each stroke. Both bilge-pumps and the air-pump are driven from a single crosshead, operated by the air-pump levers. The bilge-pump valves are simple in construction, and are fitted in the piping connected to the pumps.

In an engine fitted with a jet condenser the air-pump has to remove the condensed steam, the water used for condensing the steam, and the air which enters with the water. In a surface condensing engine the air-pump removes the condensed steam and any air which may enter the engine; the condensing water in such cases is dealt with by separate pumps, termed *circulating* pumps.

Size of Air-pump. The size of the air-pump for a condensing engine may be determined by the following rule:

$$\text{Volume of air-pump} = \frac{\text{Indicated h.p.}}{\text{revs. per min.}} \times \text{C.}$$

where C = 700 for single-acting and jet condenser,
C = 300 for single-acting and surface condenser,
C = 470 for double-acting horizontal pump and jet condenser.

Another rule is to make the capacity of the air-pump one-twelfth of the capacity of the low-pressure cylinder. There are so many contingencies to be allowed for in the working of an air-pump that pure theory cannot be relied upon in the design. The action of the pump is not perfect, inasmuch as it does not remove at each stroke an amount of water, etc., equal to its capacity. Ordinary pumps are defective enough in this respect, but air-pumps, and particularly vertical ones, are very inefficient. The speed of the pump affects its efficiency to a great extent; the best results are obtained at a bucket-speed not exceeding 200 ft. per minute; many examples are, however, to be found running at as high a speed as 450 ft. per minute at a lower efficiency.

The limit of speed is that at which the water can follow the bucket, and so provide a full barrel for the next stroke, and this in turn depends upon the vacuum maintained. The pressure of the atmosphere is 14·7 lb. per square inch, and a good vacuum is 2 lb. per square inch; it is not possible to maintain a perfect vacuum in practice. The theoretical velocity of water under a pressure of 2 lb. per square inch is 1025 ft. per minute, but it would not do to speed the pump bucket accordingly. Allowance must be made for friction, for the inertia of the water, and for the presence of air and gases in the water; this can only be determined by practice; and the speed range of 200 ft. to 450 ft. per minute as given above is deduced therefrom.

Fouls. It will be noticed, upon examination of the sectional elevation of **146**, that one bucket valve is shown dotted at the upper end of the stroke, while the bucket itself is shown at the lower end of the stroke; there is an object in doing this, and one which must be ever present with the designer of moving machinery.

Wherever one part of a machine moves relatively to another part, it must be drawn in its extreme, and sometimes intermediate, positions in order to avoid fouls. All the various movements must be carefully plotted on paper beforehand in such a way as to ensure the complete and smooth working of the whole machine. It sometimes happens during manufacture that through an oversight in the drawing office a machine cannot complete a cycle of movements without a foul of some nature.

The World's Petroleum Deposits and their Recent Development. Spouters. Oil Shales.

OILFIELDS OF THE WORLD

IN the brief account, which is all that can here be given, of the numerous oilfields of the world, the comparatively unimportant areas, supplying or partially supplying only local requirements, are necessarily ignored. Of those mentioned, the relative importance changes almost month by month with the discovery of new fields, the variations in activity of operation of those previously in work, and other causes too numerous to specify.

The Wells of the United States. Nearly every State in the Union rejoices in the possession of a greater or less extent of oil-bearing territory, the sole exceptions being some on the Atlantic coast, and some westward of the Great Lakes on the northern frontier. The several States, like the rest of the world, continually vary in the relative importance of their production of petroleum, and a purely geographical course will be the simplest to follow in a rapid sketch of the principal fields.

The Appalachian oilfields—comprising a great number of more or less independent "oil-pools," or centres of yield separated by barren areas—begin in Allegheny County, New York, and, traversing the western side of Pennsylvania and West Virginia, and portions of Kentucky and Tennessee, extend some 50 miles into Alabama, a range of about 700 miles. Throughout this length the lower portion of the Carboniferous system and the subjacent Devonian have yielded a large proportion of the American output of petroleum, though now largely depleted of oil. The great cities of Pittsburg and Allegheny at one time maintained their extensive metallurgical and kindred industries largely by means of the abundant gas present in the sands of the Catskill group at the base of the Carboniferous series, while the richest yield of oil is derived from the Chemung division of the Devonian system.

In Eastern Ohio the same rock-groups afford petroleum as in Pennsylvania, but in the interior of the State, and also in Kentucky and Tennessee, the yet lower Silurian series supplies large quantities of oil and gas. The oil, however, varies in quality from that of the higher rock-series, in containing a considerable amount of sulphur, and requiring special processes for its purification. The difference is probably due to the derivation of the Silurian limestone oil from animal remains, while the paraffin oil of the Devonian and Carboniferous sandstones appears to be of vegetable origin. In the Indiana and Illinois fields the Carboniferous, Devonian, and Silurian all supply petroleum in varying amounts. Missouri and Arkansas produce but little oil, which is of Carboniferous age. Beyond this, we find a rich oilfield in the lower Carboniferous rocks occupying the south-western parts of Kansas, and extending across Oklahoma and Indian Territory. The belt of these rocks continues across Texas to the Mexican frontier, but apparently in less productive condition, though this may be due not so much to its poverty as to neglect of testing operations, owing to the presence, further eastward in the State, of formidable rival fields in the Cretaceous and Tertiary rocks, where the additional advantage exists of being nearer to the coast of the Gulf of Mexico. Nearly every county in the eastern half of Texas is more or less petroliferous, and especially Hardin and Jefferson. These and others along the Gulf Coast comprise several independent oilfields. The coastal fields extend from Corpus Christi, Texas, into Louisiana, as far as the Atchafalaya branch of the Mississippi, and may eventually be found to range into Florida. In the West Indian Islands the petroliferous belt may be traced through Cuba, Hayti, Porto Rico, Barbados, and Trinidad, to the coast-fields of Venezuela and Colombia; while in the opposite direction it is more or less continuous from the Texas frontier throughout the Atlantic States of Mexico.

To the west of the great plains of Kansas and Nebraska rise the hills of Colorado, Utah, and Wyoming, with many oilfields of varying importance. These are mostly in Cretaceous and Tertiary rocks, but the Carboniferous, Triassic, and Jurassic systems afford minor yields in places. California has in recent years advanced rapidly to the premier position among the States in the production of petroleum, especially in the southern half of the State, including Santa Barbara, Ventura, Los Angeles, Fresno, and Kern Counties. The productive rocks are of Tertiary age.

On the southern coast of Alaska an oilfield of considerable size and promise has been in course of development for a few years in the Tertiary area eastward of the mouth of Copper River.

Mexico. One of the chief features of the development of the industry within recent years has been the extraordinarily rapid increase in the output of petroleum from the prolific oilfields of Mexico, that country having rapidly advanced to the rank of third in importance of the sources of the world's supplies.

British America. The oilfields of Western Ontario were exploited a few years after the beginning of the commercial development of the petroleum industry in Pennsylvania. The productive rock here is the Corniferous limestone, a member of the Devonian series, not petroliferous to any notable extent in the United States. In the western provinces, Alberta, Athabasca, and Mackenzie, the Cretaceous rocks give promise of a large output of petroleum when due means of communication and transport are available, but the region cannot be classed among productive oilfields at present. There are some petroliferous deposits of Lower Silurian age on the eastern coast of Quebec (Gaspé peninsula) and also on the western shores of Newfoundland.

Trinidad. Reference has been made above to Trinidad as constituting a link in the chain of oil deposits fringing the Gulf of Mexico. The Pitch Lake, one of the most popular "sights" of the island, drew more attention from travellers than from men of commerce till within the last thirty years, during which the asphalt it yields has been more and more extensively raised, and recently a

beginning has been made in the commercial exploitation of highly promising oilfields in various parts of the southern half of the island. Like all the petroleum of the Caribbean area, the oil is of Tertiary age.

Russia—The Oil-wells of Baku. The petroleum industry of Baku is probably of as great antiquity as that of Japan, to be described presently. It is mentioned by many ancient and mediæval writers, the discharge of oil-gas in the ancient fire-temple of the Guebers at Surakh ni having been the object of perennial pilgrimages from all parts of the East. The Apscheron peninsula, from the natural springs in a few square miles of which the Orient world was long supplied with petroleum, was Persian territory prior to 1723, and is mentioned, under various names, as part of that country by the earlier writers. By degrees other natural outflows were noticed in various parts of the Caucasus, but there was no systematic production from wells till 1806, when a monopoly of the trade was granted to a merchant of the name of Mirzoeff. It was not, however, till the abolition of this monopoly, in 1872, that extensive and rapid development set in. As the Baku field was the first to afford enormous volumes of oil from "spouters" or "fountains," the following account is quoted from Marvin of the Droojba fountain, which in 1883 discharged 1,600,000 to 2,000,000 gallons daily, flowing for nearly four months before the engineers succeeded in capping it—that is, closing the lining pipe:

"The fountain was a splendid spectacle—it was the largest ever known in Baku. When the first outburst took place, the oil knocked off the roof and part of the sides of the derrick, but there was a beam left at the top, against which the oil burst with a roar in its upward course, and which served in a measure to check its velocity. The derrick itself was 70 ft. high, and the oil and the sand, after bursting through the roof and sides, flowed fully three times higher, forming a greyish-black fountain, the column clearly defined on the southern side, but merging in a cloud of spray 30 yds. broad on the other. A strong southerly wind enabled us to approach within a few yards of the crater on the former side, and to look down into the sandy basin formed round about the bottom of the derrick, where the oil was bubbling round the stalk of the oil-shoot like a geyser. The diameter of the tube up which the oil was rushing was 10 in. On issuing from this the fountain formed a clearly defined stem about 18 in. thick, and shot up to the top of the derrick, where, in striking against the beam, which was already worn half through by the friction, it got broadened out a little. Thence continuing its course, more than 200 ft. high, it curled over and fell in a dense cloud to the ground on the north side, forming a sandbank, over which the olive-coloured oil ran in innumerable channels towards the lakes of petroleum that had been formed on the surrounding estates. Now and again the sand flowing up with the oil would obstruct the pipe, or a stone would clog the course; the the column would sink for a few seconds lower than 200 ft., to rise directly afterwards with a burst and a roar to 300.

A River of Oil. "Some idea of the mass of matter thrown up from the well could be formed [this account continues] by a glance at the damage done on the south side in twenty-four hours, a vast shoal of sand having been formed, which had buried to the roof some magazines and shops, and had blocked to the height of 6 or 7 ft. all the neighbouring derricks within a distance of 50 yds. Some of the sand and oil had been carried by the wind nearly 100 yds. from the fountain. . . . Standing on the top of the sand-shoal, we could see where the oil, after flowing through a score of channels from the ooze, formed in the distance, on lower ground, a whole series of oil-lakes, some broad enough and deep enough to float a boat in. Beyond this the oil could be seen flowing away in a broad chanel towards the sea."

Far larger spouters, less graphically described, were subsequently produced, one in 1893 exceeding 48,000,000 gallons daily. Fairly rich fields extend through the Daghestan, Terek, and Kuban territories, on the north flank of the Caucasus, and the province of Tiflis on the south, the Gronzi district (Terek) being especially rich. The Taman and Kertch peninsulas, between the Sea of Azoff and the Black Sea, constitute the western end of this prolific belt, which on the further side of the Caspian Sea reaches far into Turkestan. The age of the productive rocks ranges from Oligocene to Miocene in the European portion of the chain, while in the Uralsk and Ferghana regions the Cretaceous series is also contributory.

Austria and Rumania. In these countries a practically continuous oilfield extends along the outer flanks of the Carpathian Mountains and the Transylvanian Alps, affording rich yields in Galicia and Rumania, while there are indications, as yet but little developed, on the inner Hungarian side of this long curve. The minor divisions of the Galician area have undergone many changes in relative commercial importance, the Sloboda-Rungurska, Krosno, Gorlice, and Schodnica districts having been at different times the leading centres of production, now quite eclipsed by that of Borys-law-Tustanowice. Boryslaw was long noted for its rich mines of ozokerite, with little suspicion of the wealth of petroleum that lay at a greater depth. The ozokerite occurs in the marls of the Miocene age, which it traverses as plastic veins. The oil is found in the subjacent Oligocene conglomerate, to which wells of great depth have been carried. The Eocene sandstones largely contributed to the earlier production of oil in Galicia, and the Neocomian series has also been found fairly petroliferous in the western districts. In Moldavian Rumania the Eocene is again the productive series, while in the Wallachian fields the Miocene and Pliocene groups afford copious supplies, widely developed.

Germany and Italy. The chief oilfields of Germany are in Hanover and Alsace. In the latter province oil has been raised for some 400 years past from the wells of Pechelbronn, Ohlungen, and intermedaite points, the Lower Oligocene marls being the source. The principal production of Hanover centres around Oelheim and Steinförde, various secondary rocks, chiefly Triassic and Neocomian, being the source of supply. The wide plains of the Luneburger Heide, covered over by more recent deposits, are believed to conceal valuable stores of petroleum in the deep-seated members of the older rock-series. The chalk of Holle, in Holstein, is reported to be charged with petroleum.

Oil was raised and used by the Romans from wells at Agrigentum (now Girgenti), in Sicily, more than 2000 years ago. That of Miano, Parma, is mentioned A.D. 1400. At present the Italian industry is confined to production for local use, and is limited to the Emilian provinces (Piacenza,

Parma, Modena, and Bologna), the Abruzzi (Tocco and Manopello), and Campania (San Giovanni Incarico). The sources are Tertiary age, mostly Eocene, but newer in some cases.

Northern Africa and Western Asia. In Algeria, the oilfields of the province of Oran occur in Miocene rocks on both sides of the Cheliff valley, between Orleansville and Mostaganem. Approximately, the same age may be assigned to the deposits on the Egyptian shore of the Red Sea, at the mouth of the Gulf of Suez, the Arabic name of the hill, Jebel Zeit, and the Roman name, Mons Petrolius, both connoting the occurrence of mineral oil. In Syria, the oil and asphalt of the Dead Sea were known long before the petty "kings" of the Vale of Siddim met their fate in the "slime-pits" there (Gen. xiv. 10), and supplied the bitumen for embalming the countless mummies, human and other, of Egypt, *mum* being the Coptic for bitumen. In Mesopotamia, the oil-springs of Hit, on the Euphrates, furnished the "slime" cementing the bricks of the Tower of Babel and other vast erections of antiquity, the ruins of which still provide pitch for the gophers (wicker boats payed with asphalt) on the Euphrates and Tigris. In Persia, many highly productive wells have already been drilled, but a great extent of oil-bearing territory is yet awaiting development, from the Turkish frontier above Bagdad, to Bunder Abbas, on the Persian Gulf.

Assam and Burma. Profitable operations are in progress at but one point in the long belt of country constituting the foothills on the southern side of the Brahmaputra valley, at many points of which occur evidences of petroleum. The field in work is at Digboi, a few miles north of the present terminus of the Makum branch of the Assam railway system. The productive series is a division of the Miocene, but some petroleum has been found in the Eocene also.

The oil industry of Burma dates from more than a century back, having been in vigorous development in 1795. The chief source then, as now, was the Yenangyaung district, some 275 miles northward of Rangoon. Parts of this, and of the Yenangyat field, 50 miles farther north, are crowded with oil-pits sunk by natives to depths ranging to more than 300 ft., whence the oil raised is by bailing. Within recent years, Western drilling methods have been introduced, and far greater depths obtained, resulting in many excellent producers, while fresh areas, within which oil is accessible by the drill, though not by the spade, have been brought to notice by special exploration for their discovery. Traces of petroleum occur in the Eocene rocks, but the Lower Miocene alone yields a supply of commercial value, and this division is exposed at frequent intervals over an area of many hundred square miles. In Cheduba, Ramri, the Baranga, and other islands off the Arakan coast, intermittent attempts have been made, with poor success, to collect the oil there ejected by numerous mud-volcanoes from the uptilted and shattered rocks, also of Tertiary age.

The Eastern Archipelago and Japan. In the islands of Sumatra, Java, and Borneo, petroleum is raised at many points, from beds of presumably the same Upper Tertiary age as those of Assam and Burma. On the north-eastern coast of Sumatra, the Langkat fields range to Edi, in the Atchin province, and a large area in Palembang extends up the Musi to 100 miles westward and 80 miles southward of the capital. With the further opening up of the east coast, it is probable that other fields will be found in the intervening regions. In Java, a long stretch of country from Samargan to Surabaya and Madura has been found productive, and the traces detected in many other provinces may eventually extend the industry over a large part of the island. In Borneo, again, a belt of petroliferous land appears to occupy the northern coast from Sarawak to beyond Labuan, and rich fields are in work on the eastern coast in Tidung and Kutei provinces. The traces of oil alleged to occur on Celebes, Ceram, and New Guinea may be mentioned as indicative of the existence of the same productive series at those points, but in problematical extent. The Philippine Islands are reported as petroliferous at many points, and in the Portuguese division of Timor petroleum has been discovered on its southern coast.

Petroleum occurs in Japan throughout the northern islands of Hokkaido or Yezo, and large fields have been worked for many centuries in Nippon, especially on the western coast. The oilfields of the north-east coast of Sakhalin, not hitherto brought into use, are beyond the Japanese frontier in that island.

South America. As was mentioned above in connection with the West Indian Islands, rich asphalt deposits, with probably stores of unaltered petroleum beneath them, protected from escape or evaporation by the impervious cover of asphalt, occupy large areas of great promise in Venezuela and Colombia. The north-western coast of Peru, from the border of Ecuador down to Point Aguja, a distance of about 180 miles, constitutes an important oilfield. As in the smaller field of Santa Elena, in Ecuador, the productive series is of Lower Miocene age, rising in anticlinal flexures through the general covering of Upper Miocene and Pliocene beds. The inland margin is defined by the spurs of the Andes, consisting of various older rocks. In the Argentine provinces of Salta and Jujuy, and the adjacent regions of Bolivia, the Neocomian rocks are charged with petroleum over wide areas.

Oil-shales. Besides the reservoirs of petroleum and sheets of asphalt distributed, as we have seen, over every part of the world, and in rocks of nearly every geological period, there are deposits of oil-shale and lignitic coal which, while not containing any ready-formed oil, afford by distillation a fair yield of various hydrocarbons akin to or identical with the natural petroleums. A wide area of such shales occurs in the Lothians of Scotland, westward of Edinburgh, in the lower part of the Carboniferous series; and the coast of Dorsetshire possesses a belt of oil-shale of Upper Jurassic age. In France, the upper part of the Carboniferous series has valuable deposits of shale at Autun and Buxière; and in Southern Spain, the Lower Jurassic shales are practically unworked. In Prussian Saxony, between Halle, Leipzic, and Zeitz-on-Elster, is a large area of Oligocene beds with oil-lignites and shales, extensively worked for paraffin and lubricating oils. In Serbia, the Lower Miocene oil-shales occupy important areas near Alexinatz and in the Kolubara valley. In South Africa, the Portuguese territory north of Delagoa Bay is reported to possess a coast belt of Cretaceous shales of considerable width and good yield. In New South Wales, the Carboniferous series affords valuable oil-shales mined over a wide area. In New Zealand, oil-shales of Tertiary age occur in Auckland and Otago. Lastly, along the coast of Brazil from the mouth of the Amazon, for more than 1200 miles to the south, deposits of oil-shale of Eocene age occur in recesses between the spurs of the ancient crystalline rocks.

BOVERTON REDWOOD

Ratios of 15° and 75°. Formulæ for Sum and Difference of Two Sines or Cosines. Multiple Angles. Logarithms.

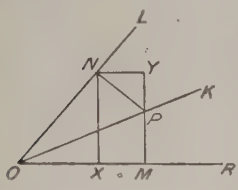
COMPOUND ANGLES

22. A. To prove that

$\sin (A - B) = \sin A \cdot \cos B - \cos A \cdot \sin B$

and

$\cos (A - B) = \cos A \cdot \cos B + \sin A \cdot \sin B.$



Let ROL be the angle A, and LOK the angle B. Then ROK is the angle (A − B). Making the same construction as before, we have ∠s PMO, PNO right ∠s. ∴ a ⊙ on OP as diameter passes through M and N. Hence ∠YPN is the supplement of ∠NPM, and ∴ is equal to ∠MON (*Prop.* 41), *i.e.*, to ∠A. Then

$$\begin{aligned}\sin (A - B) &= \frac{MP}{OP} = \frac{XN - PY}{OP} = \frac{XN}{OP} - \frac{PY}{OP} \\ &= \frac{XN}{ON} \cdot \frac{ON}{OP} - \frac{PY}{PN} \cdot \frac{PN}{OP} \\ &= \sin ROL \cdot \cos LOK - \cos YPN \cdot \sin LOK \\ &= \sin A \cdot \cos B - \cos A \cdot \sin B.\end{aligned}$$

Again, $\cos (A - B)$

$$\begin{aligned}&= \frac{OM}{OP} = \frac{OX + NY}{OP} = \frac{OX}{OP} + \frac{NY}{OP} \\ &= \frac{OX}{ON} \cdot \frac{ON}{OP} + \frac{NY}{PN} \cdot \frac{PN}{OP} \\ &= \cos ROL \cdot \cos LOK + \sin YPN \cdot \sin LOK \\ &= \cos A \cdot \cos B + \sin A \cdot \sin B.\end{aligned}$$

In the above proofs we have only considered the cases in which the ∠s A, B and (A + B) are each less than a right angle. It is left as an exercise to the student to draw the figures and modify the proofs for other values of the angles.

23. Ratios of 15° and 75°. The results of the last article enable us to find the ratios of 15° and 75°.

EXAMPLE. Find the value of tan 75°.

$$\tan 75° = \tan (45° + 30°) = \frac{\sin (45° + 30°)}{\cos (45° + 30°)}$$

$$= \frac{\sin 45° \cos 30° + \cos 45° \cdot \sin 30°}{\cos 45° \cos 30° - \sin 45° \sin 30°}$$

$$= \frac{\cos 30° + \sin 30°}{\cos 30° - \sin 30°}$$

[Cancelling numerator and denominator by $\frac{1}{\sqrt{2}}$, which is the value of both sin 45° and cos 45°]

$$= \frac{\frac{\sqrt{3}}{2} + \frac{1}{2}}{\frac{\sqrt{3}}{2} - \frac{1}{2}} = \frac{\sqrt{3}+1}{\sqrt{3}-1} = \frac{(\sqrt{3}+1)^2}{3-1} = \frac{4+2\sqrt{3}}{2}$$

$$= 2 + \sqrt{3}.$$

The other ratios of 75° can be found in a similar way. In the case of 15°, we use the fact that 15° = 45° − 30°.

24. Formulæ for tan (A ± B). We have

$$\begin{aligned}\tan (A+B) &= \frac{\sin (A+B)}{\cos (A+B)} = \frac{\sin A \cos B + \cos A \sin B}{\cos A \cos B - \sin A \sin B} \\ &= \frac{\frac{\sin A \cdot \cos B}{\cos A \cdot \cos B} + \frac{\cos A \cdot \sin B}{\cos A \cdot \cos B}}{\frac{\cos A \cdot \cos B}{\cos A \cdot \cos B} - \frac{\sin A \cdot \sin B}{\cos A \cdot \cos B}} \\ &= \frac{\tan A + \tan B}{1 - \tan A \cdot \tan B}.\end{aligned}$$

Similarly, we get

$$\tan (A - B) = \frac{\tan A - \tan B}{1 + \tan A \cdot \tan B}.$$

By the same method the student can prove that

$$\cot (A + B) = \frac{\cot A \cdot \cot B - 1}{\cot A + \cot B},$$

and

$$\cot (A - B) = \frac{\cot A \cdot \cot B + 1}{\cot B - \cot A}.$$

25. The "S, T" Formulæ. We have already proved that

$\sin (A + B) = \sin A \cdot \cos B + \cos A \cdot \sin B,$
$\sin (A - B) = \sin A \cdot \cos B - \cos A \cdot \sin B,$
$\cos (A + B) = \cos A \cdot \cos B - \sin A \cdot \sin B,$
$\cos (A - B) = \cos A \cdot \cos B + \sin A \cdot \sin B.$

By adding and subtracting the first pair of results we get

$$\left.\begin{aligned}\sin (A+B) + \sin (A-B) &= 2 \sin A \cdot \cos B \\ \sin (A+B) - \sin (A-B) &= 2 \cos A \cdot \sin B\end{aligned}\right\} \quad \ldots (1)$$

Similarly, from the second pair we get

$$\left.\begin{aligned}\cos (A+B) + \cos (A-B) &= 2 \cos A \cdot \cos B \\ \cos (A-B) - \cos (A+B) &= 2 \sin A \cdot \sin B\end{aligned}\right\} \quad \ldots (2)$$

Let A + B = S, and A − B = T. By solving these equations we find $A = \frac{S+T}{2}$ and $B = \frac{S-T}{2}$.

Substitute these values of A and B in (1) and (2). Then

$$\sin S + \sin T = 2 \sin \frac{S+T}{2} \cdot \cos \frac{S-T}{2},$$

$$\sin S - \sin T = 2 \cos \frac{S+T}{2} \cdot \sin \frac{S-T}{2},$$

$$\cos S + \cos T = 2 \cos \frac{S+T}{2} \cdot \cos \frac{S-T}{2},$$

$$\cos T - \cos S = 2 \sin \frac{S+T}{2} \cdot \sin \frac{S-T}{2}.$$

These results should be remembered *in words*, thus

(i.) *The sum of the sines of two angles equals twice the sine of half their sum, times the cosine of half their difference.*

(ii.) *The difference of the sines of two angles equals twice the cosine of half their sum, times the sine of half their difference.*

(iii.) *The sum of the cosines of two angles equals twice the cosine of half their sum, times the cosine of half their difference.*

(iv.) *The difference of the cosines of two angles* [the cosine of the *less*, minus the cosine of the *greater*] *equals twice the sine of half their sum, times the sine of half their difference.*

The student must also be able to make a ready use of the results (1) and (2); *i.e.*, he must remember that the product of a sine and cosine can be expressed as the sum of two sines, and so on.

EXAMPLE.

$$\cos\frac{3A}{2}\cdot\cos\frac{A}{2}$$
$$=\frac{1}{2}\left\{\cos\left(\frac{3A}{2}+\frac{A}{2}\right)+\cos\left(\frac{3A}{2}-\frac{A}{2}\right)\right\}$$
$$=\frac{1}{2}\{\cos 2A+\cos A\}.$$

26. Trigonometrical Ratios of Multiple Angles.

By putting $B = A$ in the formula

$$\sin(A+B)=\sin A\cdot\cos B+\cos A\cdot\sin B,$$

we get

$$\sin(A+A)=\sin A\cdot\cos A+\cos A\cdot\sin A;$$

i.e.,
$$\sin 2A = 2\sin A\cdot\cos A. \quad . \quad . \quad . \quad . \quad (1)$$

Again, from

$$\cos(A+B)=\cos A\cdot\cos B-\sin A\cdot\sin B,$$

we get

$$\cos(A+A)=\cos A\cdot\cos A-\sin A\cdot\sin A;$$

i.e.,
$$\cos 2A=\cos^2A-\sin^2A. \quad . \quad . \quad . \quad . \quad (2)$$

Since $1=\cos^2A+\sin^2A$,

it follows that

$$1+\cos 2A = 2\cos^2A$$

and
$$1-\cos 2A = 2\sin^2A,$$

or
$$\left.\begin{aligned}\cos 2A &= 2\cos^2A-1\\ \cos 2A &= 1-2\sin^2A\end{aligned}\right\}. \quad . \quad . \quad . \quad . \quad (3)$$

Also, from

$$\tan(A+B)=\frac{\tan A+\tan B}{1-\tan A\cdot\tan B},$$

we get

$$\tan(A+A)=\frac{\tan A+\tan A}{1-\tan A\cdot\tan A};$$

i.e.,
$$\tan 2A=\frac{2\tan A}{1-\tan^2A}. \quad . \quad . \quad . \quad (4)$$

These four formulæ are important, and must be remembered. They are, of course, true for *all* values of A, so that it is just as useful to know the results obtained by putting A instead of 2A. Thus we have $\sin A = 2\sin\frac{A}{2}\cdot\cos\frac{A}{2}$, and so on.

27. Sin 3A in terms of sin A.

$\sin 3A$
$= \sin(2A+A)$
$= \sin 2A\cdot\cos A+\cos 2A\cdot\sin A$
$= (2\sin A\cdot\cos A)\cdot\cos A+(1-2\sin^2A)\cdot\sin A$
$= 2\sin A\cdot\cos^2A+\sin A-2\sin^3A$
$= 2\sin A\cdot(1-\sin^2A)+\sin A-2\sin^3A$
$= 2\sin A-2\sin^3A+\sin A-2\sin^3A$
$= 3\sin A-4\sin^3A.$

In a similar way we obtain

$$\cos 3A = 4\cos^3A-3\cos A.$$

LOGARITHMS

28. By algebra we know that

(i.) The index of the *product* of two powers of the same quantity is obtained by *adding* the indices of the powers.

(ii.) The index of a *quotient* is obtained by *subtracting* the indices of the powers.

(iii.) The index of a *power* or a *root* is obtained by *multiplying* or *dividing* the indices.

These facts are made use of to shorten arithmetical calculations. A power of the number 10 can be found which is practically equal to any given number. For example, 2 is approximately $10^{\cdot30103}$. The number 10 thus used is called the *base*; the index ·30103 is called the *logarithm* of 2 to the base 10. Hence,

DEFINITION. The *logarithm* of a number to a given base is the *index* of the power of the base which is equal to the given number.

Logarithms to the base 10 are, in general, incommensurable numbers. They have been calculated to seven significant figures, for all numbers from 1 to 100,000.

$\text{Log}_{10}2 = \cdot30103$, and $10^{\cdot30103}=2$, are different ways of stating the same fact.

29. From the index laws of Algebra we have

(i.) The logarithm of the *product* of two numbers is equal to the *sum* of the logarithms of the numbers.

(ii.) The logarithm of the *quotient* of two numbers is the logarithm of the dividend *minus* the logarithm of the divisor.

(iii.) The logarithm of a number raised to the *power p* is *p times* the logarithm of the number.

30. Since $10^0 = 1$, *the logarithm of* 1 is 0. Also, since $10 = 10^1$ and $100 = 10^2$, the logarithm of a number between 1 and 10 lies between 0 and 1, and that of a number between 10 and 100 lies between 1 and 2, and so on. Thus, *the logarithm of a number greater than* 1 *is positive.*

Again,
$$\cdot1=\frac{1}{10}=10^{-1},$$
$$\cdot01=\frac{1}{100}=10^{-2},$$

and so on, so that *the logarithm of a positive number less than* 1 *is negative.*

It is clear that the logarithm of a number between 1 and 10 is a positive decimal fraction; the logarithm of a number between 10 and 100 is equal to 1 + a decimal fraction, and so on.

Also, the logarithm of a number between 1 and ·1, *i.e.*, between 10^0 and 10^{-1}, lies between 0 and −1, and is therefore a negative decimal fraction. This *is equivalent to* $-1+$ *a positive decimal fraction.* Similarly, we see that the logarithm of a number between ·1 and ·01 can be written in the form $-2+$ a positive decimal.

H. J. ALLPORT

Economic Regions of the Russian Empire. The Siberian Railway. Rumania. Bulgaria. Serbia. Scandinavia. Austria-Hungary and the Mediterranean Nations.

THE TRADE OF EUROPE

We now turn to those European lands which are still in an early stage of industrial development and international trade on a large scale. Russia is by far the largest of these, and consequently possesses far the greatest potentialities. It is the greatest continuous land empire in the world, with an area of 8,000,000 square miles, containing a population of over 140,000,000 people [see GEOGRAPHY, pages 2397 and 2132-5]. In position and products it may be compared with Canada, but it is two and a half times as large, and its population is twenty times as great. It differs from its Canadian prototype in its western or European portion, and in Transcaucasia, Transcaspia, and Turan it exhibits a type markedly unlike anything in Canada.

The Four Zones of Russia. The four characteristic zones of tundra, forest or taiga, steppe, and desert have already been described. Except on its arctic and forest margins, both of which produce furs, the vast barren region of *tundra* is as yet economically valueless. Gold, however, is abundant in the north-eastern portion of Arctic Russian Asia, and, as in the corresponding Yukon region of Canada, will probably lead to a considerable development of mining enterprise.

The *taiga*, or forest zone, is already exploited to some extent for timber, wood-pulp, and other forest produce. In the main, however, it is a vast undeveloped asset. Wood is used for domestic purposes, as fuel for locomotives, and to feed the smelting furnaces of the Ural mining district.

The Mineral Wealth of the Forest Zone. The mineral wealth of this zone is considerable. It is greatest in the province of Perm, where it has long been exploited. Gold (in the Tura and Tagil valleys), platinum (now the most valuable industrial metal in the world), lead, copper, and tin are the chief metals, and Perm, Yekaterinburg (iron mines), Nizhni Tagilskyi (copper and platinum) are the most important mining centres. Magnetic iron ore is found in Finland, where granite quarries and the deposits of kaolin clay are beginning to be utilised by one of the most intelligent populations in Europe. Other mineral centres in the forest zone, which extends right across European Russia and far across Asiatic Russia, are the Altai Highlands (gold and silver), and the eastern mountains of Transbaikalia and Amuria (gold and tin). The Siberian graphite mines at Alibert are the most important in the world. Coal is now mined in the Southern Shenka district, between Tomsk and Maryinsk, in the Kirghiz steppe (where copper is also found), near Irkutsk, in the Southern Usuri region, near Vladivostok, and in Sakhalin.

In European Russia agriculture is possible, and has long been carried on in the numerous forest clearings. Rye and hemp are the chief crops cultivated, especially in the west in the Baltic provinces, whence most of the hemp supply of Europe is obtained.

Industries in this region, outside the metal smelting already mentioned, are developing around the coalfields of Poland, where Warsaw and Lodz are great cotton centres [see page 2134], and in the Moscow district, the latter using coal from the Oka coalfield round Tula. Moscow, Tver, Yaroslav, and Ivanovo (the latter known as the Russian Manchester) manufacture the raw cotton brought from the irrigated oases of Russian Central Asia. To a smaller extent, manufactures are also important at Petrograd and Narva.

A Stock-raising and Wheat-growing Region. The *steppe*, in its primitive economic condition, is a stock-raising region. The climate of the whole region is dry, but in the western part, which has the least scanty rainfall, the fertile black soil, *chernozoim*, is very fertile when cropped. Wheat is largely grown for export, while the cheaper rye supplies the food of the farming population. This may be compared with the similar conditions in India, where millet is the native food, and wheat is grown only for the European market. In both cases this recent development has been made possible by modern facilities of transport, the great magician of the modern world.

The *wheat* of this zone is a very important item in the world's supply. It is carried to the ports of the Black Sea (Ochakof, Odessa, Kherson, Taganrog, Rostof, and others) for export. For reasons explained in the case of Canada, milling is growing in importance at such centres as Odessa, where macaroni is manufactured.

The coal, iron, and manufacturing industries, though only of recent origin, are becoming firmly established in the steppe zone. Coal is mined in the Donets basin, and supplies the linen, tobacco, soap, and sugar manufactures of Kharkof. It is also used to smelt the red hæmatite and specular iron ores of Krovoi Rog, some hundred miles north of Kherson. Kief, on the margin between forest and steppe, manufactures linen and sugar from locally grown flax and beet.

In the irrigated lands of the *desert* zone enormous attention is being paid to the cultivation of cotton, which is sent to the cotton mills of Moscow and other textile centres of the Oka coalfield [see above]. The oil industry has been described on page 2398.

The Value of the Great Siberian Railway. Internal communications are improving year by year. The construction of the great transcontinental line of the Siberian Railway may be compared with the construction of the Canadian Pacific line. The first great step of providing through communication between the extreme east and west of a vast dominion having been achieved, Russia, like Canada, is now pushing on the work of spreading a network of branch lines into the unbroken lands on either side, and is linking up the Siberian line with the Central Asian lines. The examples of the United States and Canada leave no reason to doubt that this will be followed by a rapid extension of settlement—in this case, eastwards—and by the rapid utilisation of what is still, for the most part, an undeveloped asset, though of enormous potential richness.

Russian Exports. The Russian exports are even more difficult to analyse than those of the United States. Russia carries on a Baltic, a Black

Sea, a small Caspian, and a considerable Pacific trade. It has also a large overland trade, especially with the Central European Powers, and with its neighbours in Asia. Statistics distinguish between trade which crosses the European frontier, including the Caucasus, trade with Finland, and trade which goes across the Asiatic frontier. The figures are given in millions of roubles—1,000,000 roubles are worth rather more than £105,000.

Year	Trade across European frontier and Black Sea frontier of Caucasus	Trade with Finland	Trade across Asiatic frontier	Total
1905	954·4	38·3	54·3	1047·0
1910	1228·8	42·8	177·5	1449·1
1913	1365·5	55·3	162·4	1583·2

Excluding trade across the Asiatic frontiers, the following are the exports for 1913, the last year for which complete figures are available.

Class of export	Value in millions of roubles	Percentage
Articles of food	807·2	56·9
Raw and partly manufactured goods	550·2	38·7
Animals	32·9	2·3
Manufactured goods ..	30·4	2·1
Total	1420·7	100·0

These figures may be compared with those for Canada, with which they present a general similarity, though animals and manufactured goods bulk larger in Canada than in Russian exports. Of the articles of food exported from Russia, wheat is much the most considerable item. The principal raw and half-manufactured goods are timber and wooden goods from the forest zone. Cotton goods and flax from the agricultural zone, naphtha from the oil districts, to the value of 40·8 million roubles, and sugar to the value of over 20·4 million roubles, are the chief exports across the Asiatic frontier.

Imports. Taking the same classification of commodities as for the exports, the following were the imports into Russia in the same year, 1913.

Class of import	Value in millions of roubles	Percentage
Articles of food	163·0	13·3
Raw and partly manufactured goods	600·9	49·3
Animals	3·0	0·2
Manufactured goods ..	453·4	37·2
Total	1220·3	100·0

In the initial group, fish is first in value, closely followed by tea, and then by wine and spirits, among the foods. Raw cotton is by far the most important import, accounting for about one-tenth of the total value of the imports. Raw metals, coal, wool, and gums and resins are the next in order of value among the raw and partly manufactured goods. Machinery, metal goods, and textiles are the principal manufactured articles imported. Compare, again, with Canada.

Across the Asiatic frontier the imports are tea from China, but in diminishing quantities; rice (7·0 million roubles) from Persia, and raw cotton (13·8 million roubles) from Russian Central Asia, the latter in increasing quantities.

Countries with which Russia Trades. As might be expected, the German Empire has hitherto been Russia's best customer, the trade passing both overland and by the Baltic. The United Kingdom is second, sending in coals and manufactured goods in exchange for timber, hemp, flax, and some cereals, through the Baltic ports, and receiving large quantities of cereals through the Black Sea ports.

The following table indicate the value of Russia's trade with some of her most important customers.

Country	Imports from	Exports to	Total
	Millions of roubles	Millions of roubles	Millions of roubles
Germany	642·7	452·6	1095·3
United Kingdom ..	170·3	266·8	437·1
Netherlands	21·5	177·4	198·9
France	56·0	100·8	156·8
Finland	50·9	55·2	106·1
Austria-Hungary.	34·6	65·2	99·8
Italy	16·7	73·6	90·3
United States ..	74·1	14·1	88·2
Belgium	8·6	64·6	73·2

The distribution between the imports and exports in the case of the United States is accounted for by the large imports to Russia of raw cotton. To Belgium grain and flax are exported.

The Scandinavian Lands. Sweden and Denmark broadly resemble the other Baltic lands, Western Russia and Northern Germany. They consist of morainic lake-lands, interspersed with peat bogs. Forests are numerous, and timber, joinery, wood-pulp, and resins are among the exports. Agriculture is carried on in the clearings of Southern Sweden, and dairy farming (butter, cheese, eggs, bacon) is a staple industry of Denmark. Sweden possesses rich deposits of iron ore at Dannemora and Gellivara [see page 1343].

Sweden. Nearly half the population (45 per cent.) of Sweden live by farming, a quarter by manufactures, trade, and transport, and 6 per cent. by mining. The manufacturing classes are engaged chiefly in iron, steel, and engineering works, textile and shoe factories, sugar mills and sugar refineries, breweries, flour mills, and tobacco factories. The trade of Sweden is summarised by the tables for 1912, given below, in thousands of kronor—18 kronor equal £1.

Exports	Value in thousands of kronor	Imports	Value in thousands of kronor
Timber	285,365	Minerals, mainly coal	123,416
Metal goods and machinery ..	114,908	Metal goods and machinery ..	88,208
Live animals and animal foods ..	99,825	Raw textile material and yarn	75,781
Minerals	80,893	Wheat and flour	68,217
Metals	47,880	Colonial produce	60,340
Paper	40,352	Textile manfres.	53,996

The overwhelming importance of timber in these returns is obvious. Next come minerals and mineral products, animals and animal foods.

Of the total foreign trade of Sweden, 27 per cent. is carried on with Germany, the imports largely exceeding the exports, and 26 per cent. with the United Kingdom, in which case the exports exceed the imports. Next in order among the customers of Sweden are Denmark, Russia, France, and Norway. In 1912 the total value of the exports was 760,616,000 kronor, and the total value of the imports, 793,713,000 kronor.

Trade of Denmark. The trade of Denmark well illustrates the uniformity of the country, and the remarkable economic development of recent years. In 1912 the exports of the home produce were worth 596,723,000 kroner (18 kroner equal £1), and of this butter accounted for 191,088,000 kroner, meat for 176,144,000 kroner, and animals for 54,182,000 kroner.

The position of Copenhagen on the Sound, at the point of vantage between the North and Baltic Seas, makes Denmark a relatively important trading country. In 1912 its total value export trade was worth 682,082,000 kroner, of which home products formed about 87 per cent. Over 54 per cent. of this trade went to the United Kingdom, nearly 27 per cent. to Germany, and over 7 per cent. to Sweden and Norway.

The import trade of Denmark is largely in cereals (14·6 per cent.), metals and hardware (9·3 per cent.), coal, of which little is produced in the country (8·2 per cent.), textiles (7·3 per cent.), and colonial produce (5·8 per cent.). The total value of the import trade in 1912 was 817,512,000 kroner, of which over 740,000,000 kroner represented special imports. A remarkable feature of the trade returns is the import of provisions and eggs, which accounts for 6·9 per cent. of the total import trade.

These are collected from the other Baltic lands, to be shipped to Britain and other countries through Copenhagen.

Nearly two-fifths of the imports come from Germany (over 38 per cent.), and less than 17 per cent. from Britain. Sweden and Norway together supply 9 per cent., the United States 8·4 per cent., and Russia nearly 7 per cent. Its flourishing provision trade, the staple of its prosperity, is the result partly of the climatic conditions and partly of the excellent technical education given to its people. Its entrepôt trade is explained by its position.

Norway. Norway, the rugged land which occupies the western highlands of the Scandinavian peninsula, differs completely from Sweden and Denmark in configuration and climate. Its economic conditions are correspondingly different. Three-quarters of the surface of the country is unproductive; and of the remaining quarter, 21·5 per cent. is forested, leaving only 3·5 per cent. fit for cultivation. Under these conditions, maritime occupations (fishing, shipbuilding, the carrying trade, etc.) naturally rank among the principal industries of the country. Thirty per cent. of the population are engaged in agriculture, but to a very large extent these supplement their resources by fishing.

The figures for the export trade of Norway show how much the prosperity of the country depends on the fisheries and the forests. The figures for 1912 are given below. The krone has the same value as given above.

Exports	Kroner
Animal produce (malty food)	109,069
Timber and wooden goods	84,961
Hair and skins	27,313
Paper and paper manufactures	25,366
Minerals (raw)	17,458
Minerals (manufactured)	16,769
Tallow, oils, tar, etc.	15,709
Metals and metal manufactures	14,663

The import trade of Norway naturally consists largely of breadstuffs, since the country cannot raise its own, and groceries. Metals and machinery also form a considerable item. The figures for 1912 are:

Imports	Kroner
Vessels, carriages, and machinery	81,507
Breadstuffs	62,512
Minerals (unwrought)	58,527
Textile manufactures	43,520
Groceries	40,116
Tallow, oils, tar, etc.	39,925
Metals (manufactured)	37,237
Metals (unwrought and partly manufactured)	35,016

Among the customers of Norway, Germany now occupies the first place, being closely followed by our own country. Norway sends to Britain wood and wood-pulp, fish, stones, ice, and in return receives coal, cottons and woollens, machinery and ironwork. Fish is largely exported to Spain, Italy, and other Catholic countries. The mercantile marine has a total tonnage of nearly 1¾ million. Compare the German Empire (3 million tons).

Rumania. Rumania [see GEOGRAPHY, page 1872] resembles Southern Russia. Its great steppe-lands rise to the forested slopes of the Carpathians and Transylvanian Alps, so that agricultural and forest products form the staple of its natural resources; 60 per cent. of the population are engaged in agriculture.

The following table shows the nature of the trade in 1911, in thousands of pounds.

Exports	£1,000	Imports	£1,000
Grain	22,306	Metals and metal manufactures	4,902
Petroleum	1,585	Textiles	3,662
Beans and oil seed	1,408	Machinery	2,366
Wood	1,030	Wool, hair, and manufactures	2,045
Foodstuffs	265	Ready-made clothing	1,132
Animals	258	Hides	920

Cereals, forest produce, animal products, and oils from the petroleum wells are among the chief exports through the Danube ports, the most important of which are Galats and Ibraila. The exports go to Belgium, Austria-Hungary, the United Kingdom (wheat, barley, maize, petroleum, and timber), France, and Italy. The imports are obtained from the German Empire, Austria-Hungary, the United Kingdom (cottons, cotton yarn, iron, machinery, coal, and woollens), France, Italy, and Belgium. The total value of the exports in 1911 was 691,720,000 lei (25 lei = £1), and of the imports, 569,745,000 lei.

Bulgaria. Bulgaria somewhat resembles Rumania in the north, but it is narrower and less fertile. The chief agricultural area is in the Maritsa and Tunja valleys [see page 1874]. Cereals are exported to the United Kingdom, Belgium, Turkey, the German Empire, Austria, and France, and account for three-fifths of the total exports. The others are live-stock and their products, silk cocoons, and attar of roses. Textiles form one-third of the imports, and metals, machinery, and implements one-sixth. The imports come chiefly from Austria-Hungary (24 per cent.), Germany (20 per cent.), the United Kingdom (15 per cent.), and France (7 per cent.). The imports from Britain are cottons, cotton yarn, machinery, and metals. In 1912 the total value of the exports was £6,257,000, and of the imports, £8,524,000.

Serbia. Serbia is more rugged and forested than Bulgaria, and has a much smaller trade. Animals and animal products formed one-fourth of the exports in 1912, and cereals nearly one-third. Two-fifths of the export trade was with Austria-Hungary, and one-fifth with Germany. By controlling the trade routes from Serbia, Austria-Hungary was formerly able to exert an economic influence over Serbia, which is hardly less valuable than a political one. It has been said, indeed, that Austria's habitual method of curbing Serbian advances to other Powers is to proclaim the existence of swine disease in Serbia, and to prohibit the export of swine from that country into Austria-Hungary. The chief imports are cotton and woollen goods (20·5 per cent.), metals and machinery (20·8 per cent.), hides and leather (5·5 per cent.). Of these, 45 per cent. comes from Austria-Hungary, 30 per cent. from Germany, and only 8 per cent. from the United Kingdom. The total value of the exports in 1912 was 84,221,000 dinars, and of the imports, 106,094,000 dinars (1000 dinars = £40).

The Kingdom of Hungary. From an economic as well as from a political point of view, Austria-Hungary must be regarded as consisting of two groups of Powers. *Hungary* resembles Rumania in many respects, but has a greater mineral and industrial development, in addition to more extensive territories. The fertile plains or pastures of Hungary are no longer exclusively pastoral, but rich agricultural lands; 43 per cent. is arable, and 22 per cent. meadows and pasture land. The slopes of the Carpathians and other mountains are densely forested, so that 27 per cent. of the country is covered with trees. The agricultural and forest resources support 65 per cent. of the population. The rocks are rich in minerals, especially in the Bihar region, and in the North Hungarian Ore mountains, where gold, silver, copper, lead, antimony, mercury, and other minerals abound, but are not exploited as they might be. The mineral riches of Hungary will undoubtedly be a greater source of wealth in the near future.

The chief wealth of Hungary is agricultural. On the flat steppe-lands rich crops of wheat and maize are grown. The wheat is of extremely fine quality. Much of it is ground by the most modern processes, the different qualities being sorted out beforehand. Hungarian flour is the best on the market, and is better than flour ground in our own country by the same processes from Hungarian wheat. This is probably due to different climatic conditions, and to the effect of the voyage on the wheat. Budapest, Temesvar, and Poszony (Pressburg) are the chief milling centres, and Fiume the chief outport, but some of the wheat is sent down the Danube. Oats, barley, and rye are also grown.

Among other agricultural products are potatoes, beetroot, pulses, tobacco, hops; and even a little rice is grown in the Banat. Horses, cattle, pigs, and sheep are numerous. Hungary is noted for its vineyards, and its silk culture supports over 66,000 families.

Hungarian Manufactures. Manufactures are rapidly developing in Hungary. As in Canada and other lands where agriculture is expanding, much of the industry is connected with the elaboration of food, agricultural implements, and transportation plant. Thus, Budapest and Poszony (Pressburg) mill flour, and also make jute sacks for holding it, and the necessary machinery and rolling stock. Breweries and sugar-mills are numerous and important. Agram, in Croatia, is noted for its tobacco factories. The following figures, from the census of 1900, show the relative importance of the different manufactures, which occupy 12·8 per cent. of the working population—in clothing, 25 per cent.; in foodstuffs, 14 per cent.; in iron and other metals, 11 per cent.; in building, 11 per cent.; in wood and bone, 8½ per cent.

In 1912 the following was the value of the exports and imports in thousands of crowns (£40), each crown or kroner being equal to 9¾d.

Exports	Thousands of crowns	Imports	Thousands of crowns
Cereals	311,643	Cottons	197,537
Flour (wheat)	272,853	Machinery	130,812
Cattle (horned)	177,603	Woollens and semi-woollens	125,591
Swine	90,177	Ironware	91,350
Wine	67,855	Leather (prepared)	75,796
Timber	66,371	Coal	65,051
Sugar (raw)	65,050	Clothes	56,432
Sugar (refined)	44,505	Leather goods	53,886

Of the imports, 23 per cent. consist of raw materials, 14 per cent. of semi-manufactured articles, and 63 per cent. of manufactured goods. On the other hand, raw materials furnish over 50 per cent. of the exports, manufactured articles 40 per cent., and semi-manufactured articles 10 per cent. The prosperity of Hungary is essentially agricultural.

The Austrian Empire. The Austrian Empire [see page 1869] is more diverse economically than the kingdom of Hungary. It has to be divided into (1) Galician Bukovina, Bohemia, Silesia, and Moravia; (2) Austria proper; (3) Alpine provinces, Bosnia and Herzegovina; (4) coastal provinces.

Half the population depends on agriculture and forestry, and about one-quarter on various industries, manufacturing, metallurgic, etc., while nearly 8 per cent. are supported by trade and transport, and over 2 per cent. by mining; 38 per cent. of the land is arable, 35 per cent. is woodland, and 25 per cent. is pasture and meadow land.

Wheat, barley, rye, and oats are all extensively cultivated. Potatoes are a most important crop; maize, pulses, beet (in Bohemia), and vines are next in importance. Considerable areas, especially in Bohemia, are covered with flax, hemp, and hops. Live-stock is abundant. In valleys opening to the Adriatic silkworms are reared.

The mineral wealth is mainly coal in Silesia; coal, lead, zinc, silver, alum, and graphite in Bohemia; iron, zinc, and lead in Alpine states; iron, petroleum, and salt are found in the Carpathian foreland; copper is obtained in Salzburg, and mercury at Idria.

Austrian Manufactures and Trade. Manufactures are growing rapidly in importance, especially near the coalfields of Bohemia, Moravia, and Silesia, where iron manufactures are flourishing. Bohemia makes sugar from beetroot, much beer, especially at Pilsen, and brandy; cottons and woollens are manufactured at and around Reichenberg in the north, and linen and leather goods. Bohemia is also famous for its glass and porcelain. Vienna, like Prague and most other capitals, makes many articles of luxury, more particularly furniture, silk and dresses, and boats for the Danube. Paper is made in the forested Alpine provinces and Northern Bohemia.

TWO GREAT SEAPORTS OF THE CONTINENT

MARSEILLES—THE GATEWAY OF FRANCE INTO THE MEDITERRANEAN

A QUAY AT ROTTERDAM, THE RISING OCEAN PORT OF HOLLAND
(The lower photograph is by Mr. H. W. Nicholls)

The trade of Austria with the East consists of the exchange of manufactured goods for food and raw materials, but with the West it is rather an exchange of raw and half-manufactured goods for finished wares. The down-Danube trade is with Hungary and the Balkans, the up-Danube trade with South Germany. From Bohemia, trade passes by the Elbe valley to a North Sea outlet. Austria has its port in Trieste, on the Adriatic, with connections especially with Mediterranean and eastern ports.

Austria-Hungarian Trade. The trade of Austria-Hungary is five-sixths by land and one-sixth by sea. Naturally, most is with the adjoining lands of the German Empire, Italy, Russia, the Balkan States, Switzerland, and the not-far-distant France. British trade is largely through the Adriatic ports, and ranks second.

The exports and imports of the Common Customs Territory, which includes Austria-Hungary, the occupied territories of Bosnia, Herzegovina, and also the Principality of Lichtenstein, are :

Exports—1913	Thousands of crowns	Imports—1913	Thousands of crowns
Sugar	292,880	Cotton (raw)	336,075
Timber	247,493	Coal, coke, etc.	262,827
Eggs	137,372	Wool	141,478
Glass and glassware	88,264	Hides and skins	115,571
Lignite	76,524	Silk and manufactures	114,408
Woollens	64,809	Coffee	93,390
Leather gloves and shoes	60,623	Flax, hemp, and jute	85,910
Malt	55,697	Maize	83,806
		Machinery	80,837

Economic Decay and Advance in the Mediterranean Countries. The Mediterranean climate and products have received special attention in previous chapters. [See pages 1872 and 2004]. The peculiarity of rain falling in the winter half of the year is of great economic significance.

The economic development of the Mediterranean countries, however, depends partly on the configuration and position of the country, but even more on the stage of advancement of the population. In this long-settled area can be traced the rise and fall of peoples better than elsewhere, and the effects, economic and social, of different economic régimes.

Asia Minor, once the most prosperous part of the Mediterranean basin, is now the least so. The decay has been largely due to the neglect of roads and irrigation, the two ways which formerly permitted the circulation both of commodities and of the fertilising streams to the fields. The substitution of a pastoral for an agricultural civilisation leads inevitably to a decrease in the food-producing possibilities of the land, as well as to the diminution of its trading capacity, and the decay alike of its commercial routes and of the Government which protects a settled population.

Egypt, on the other hand, has progressed enormously in recent years through the security afforded by the reform of its government and the improvement of its irrigation.

Turkish and Egyptian Trade Compared. For the last three years for which figures are at present available, the average imports into Turkey amounted to £T34,000,000 (£T10 = £9 sterling), while the exports were valued at nearly £T20,000,000.

The following table shows the principal imports and exports in 1910-11 :

Imports	£T1000	Exports	£T1000
Textiles	13,864	Textiles	5,434
Cereals	4,810	Fruit	4,340
Sugar	3,229	Tobacco	2,705
Metals and manufactures	2,664	Cereals	1,991
Oils and fats	1,639	Drugs	1,397
Hides and skins	1,404	Animal products	1,018
Coffee, tea, spices	1,115		
Total	37,774	Total	22,474

The largest trade is with Great Britain, which sends 20 per cent. of the imports and takes 25 per cent. of the exports. Next in order come Austria-Hungary, France, and Germany.

With these trade figures compare the returns for Egypt for 1913 (£E1 = £1 0s. 6½d.). Perhaps the most telling proof of the advance of Egypt in recent years is to be found in a comparison of the trade for 1913 with that of ten years earlier :

Imports	1903 £E1 000	1913
Textiles	4,957	6,969
Cereals and vegetables	1,698	4,242
Wood and coal	2,222	3,838
Metals and manufactures	2,243	3,145
Spirits, oils	884	1,411
Chemical products	456	1,342
Provisions and drugs	441	1,066
Animals and animal products	781	1,051
Total	16,753	27,865

Exports	1903 £E1000	1913
Raw cotton	15,676	25,513
Cereals and vegetables	2,364	4,297
Tobacco	423	394
Animals and animal products	137	297
Skins and leather goods	82	237
Total	19,541	31,662

Nearly one-third of the imports come from Britain, in return for about two-fifths of the exports. Germany, France, and Austria-Hungary rank next in importance in the foreign trade of Egypt.

Greece. With its mountains and narrow plains, Greece is not suited to great agricultural development, yet the bulk of the people are directly dependent upon the products of agriculture. Currants and iron ore are the chief exports, with wines and oil secondary ones. One-third of the imports are agricultural products, and one-seventh raw minerals. By far the largest trade is with Great Britain.

The Western Mediterranean Lands. The western lands are much more advanced, and present a considerable economic contrast to those of the eastern basin. The lowlands are greater in area, and are more carefully cultivated. Wine and oil form an even more important part of their products. There is little industrial development, except in Northern Italy, Southern France, and round Barcelona, in Spain. Portuguese, Algerian, and Tunisian statistics are more comparable with those of the Eastern lands. Algerian, Moroccan, and Tunisian trade is still largely agricultural. Over 31 per cent. of the exports from Tunis, which are valued at 155,000,000 francs, consist of phosphates, 15 per cent. of mineral ores (iron, lead,

and zinc), and 13·5 per cent. of olive oil. In good years cereals form a considerable proportion of the exports. Textiles, grain and flour, iron, hardware and machinery, sugar, and coal are the principal imports. The bulk of the trade is with France. Next come Italy, Britain, and Algeria.

Algerian and Moroccan Trade. Algerian trade is much larger. The exports are worth over 508,000,000 francs. They resemble those of Tunis in many respects, but wine is the chief export, forming 30 per cent. of the total; cereals account for nearly 12 per cent., sheep for over 6 per cent., and hides, skins, and wool for 4·5 per cent. The imports resemble those of Tunis.

Over 80 per cent. of the total trade is with France, Britain coming next with little over 3 per cent. Germany and Italy both figure more prominently in the export than in the import columns, while Brazil, Spain, and the United States are more prominent in the import columns.

Moroccan trade is comparatively small. Products, such as eggs, almonds, wool, wax, birdseed, and beans, which require no great care to produce, are exchanged for cotton, sugar, and tea. The exports of grain (barley and wheat) are increasing. Two-fifths of the trade is with France and Algeria, and nearly 29 per cent. with Britain and the British possessions in the Mediterranean.

Portuguese Trade. Nearly half the country of Portugal is waste land, and 26 per cent. is under cultivation. Vineyards occupy 35 per cent., fruit-trees 3·9 per cent., and forest 17·3 per cent. of the total area.

Wine (over one-half of it port) is by far the most important export (nearly one-third), and cork comes next (one-eighth). Fish (especially tinned sardines), fruits, cotton, timber, and copper ore are other important exports; 24 per cent. go to Britain, 20 per cent. to Spain; 22 per cent. to Brazil, and 16 per cent. to the Portuguese colonies. Britain obtains 22½ per cent. of its wine from Portugal. Cotton and cotton goods, iron and steel manufactures, coal, wheat, codfish, sugar, hides and skins, and machinery are among the chief imports; 30 per cent. come from Britain, 18·6 per cent. from Germany, 9 per cent. from the United States, and 8 per cent. from France, Belgium, and from Spain.

The position of Lisbon makes it an important entrepôt centre, to and from which is carried produce from South America, more particularly from Brazil and from the Portuguese colonies.

Economic Divisions of Spain. There are four great areas in Spain: (1) The forested and mineral mountains of the north; (2) the pasture-lands of the Meseta and the Ebro valley, which are only here and there cultivated; (3) the mineral zone of the Sierra Morena and Sierra Nevada in the south; and (4) the fertile plains of Andalusia and the terraced hillsides of the coastal regions of the Mediterranean. In this region is Barcelona, the chief manufacturing centre, noted for its cottons, silks, woollens, and paper (made largely from esparto grass).

Spain has two outlets: (1) by the Mediterranean to the east and south and west; and (2) by the Atlantic to the west and north. The internal routes are poor and inadequate, and this greatly hampers Spanish economic development. One-third of Spain is cultivated, one-fifth produces fruits, and another fifth is under grass, while nearly 4 per cent. consists of vineyards.

Spanish Exports and Imports. From the north of Spain iron and iron ore and partially manufactured iron are exported, especially from Bilbao, where there are many ironworks. Some zinc and cobalt are also exported from this district. The southern mineral zone yields much copper (exported from Huelva), silver, silver-lead, lead, and mercury (Almaden). Metals and mineral ores amount to 24 per cent. of the total value of exports—1,146,000,000 pesetas (say, 33⅓ pesetas = £1).

The wine, grapes, and raisins shipped from the Mediterranean ports and Cadiz amount to nearly 25 per cent. of the exports.

Spanish imports include alimentary products, such as grains to a percentage of 16 per cent. of the total of 1,140,000,000 pesetas in 1904, while raw cotton formed 11·5 per cent. Iron, steel, and machinery formed 12 per cent. of the imports, and coal over 6 per cent.

Spanish trade relations are worth analysing. The eight States with the greatest trade are:

Country	Exports to	Imports from
	1000 of pesetas	1000 of pesetas
United Kingdom ..	236,229	200,597
France	257,681	182,954
United States	67,328	155,232
Germany	74,340	138,330
Portugal	50,279	56,858
Argentina	71,643	39,576
Belgium	49,913	33,122
Cuba	63,643	3,452
Italy	48,752	12,680

The preponderance of exports in the case of Britain, France, and Cuba is to be noted. To Britain and France are sent much iron ore, wine, and fruits; to Cuba, wines and manufactured articles. Britain, France, the United States, and the German Empire supply most of Spanish imports, mainly manufactured articles, with cereals, and cotton, in addition, from United States.

Economic Divisions of Italy. Italy is mainly agricultural, and over 70 per cent. of its surface is productive. Wheat is grown on 23 per cent. of the area under crops, and vines on 20 per cent., the olive groves and maize fields being next in importance. On the hill slopes mulberry and other trees flourish. On the Alpine meadows and grassy flood-plains many cattle are kept, and cheesemaking is important.

Apulia, which produces hard wheat from which macaroni is made, in the east, is divided by the Apennines from the fertile flood-plains and hill slopes of the west, while the Sicilian region and the Neapolitan Campagna, with their lemon, orange, and olive groves and vineyards, and Tuscany, with fewer oranges and more vines and olives, are the most productive. Except sulphur from Etna, marble from Carrara, iron ore from Elba, and some iron, silver, lead, and zinc from Sardinia, the produce is mainly fruits and wine and olive oil, with straw plait, and artistic articles for tourists.

Northern Italy is shut in by mountains. The irrigated northern plains are cold in winter, very warm in summer, so that not only wheat and maize but even rice is grown. The perennial streams yield abundant water supply for the electric power which is so important in an area where there is no coal. The chief manufacture is silk, the silk-worms being fed on the mulberry leaves, and the cocoons unwound in many villages. The chief

centres are Como, Brescia, Bergamo at the opening of Alpine valleys, and Milan, the great city of the plain. Engineering works have become of great importance at Milan, Turin, and other centres.

The outlets of this northern region to the sea are by Genoa, reached by fairly easy passes, and, to a less degree, through Venice. The Alpine tunnels connect it with the colder lands of Central and Western Europe, to which its richer produce is sent.

Italian Exports and Imports. Of Italian exports, raw silk is by far the most important, forming 13·5 per cent. of the total of nearly 2,500,000,000 lire (25 lire = £1). Cottons, dried fruits, silk manufactures, wines, cheese, hides, flax and hemp, eggs, olive oil, sulphur, and flour come next. Germany, Switzerland, Britain, the United States, and France are the chief customers for the exports of Italy; next come Austria-Hungary and the Argentine Republic, to which so many Italians have emigrated.

Over a series of years raw cotton takes first place in the list of imports, but in 1912 and 1913 its value was exceeded by those of wheat and coal, Italy being devoid of coal. Next in importance are the imports of timber, hides, boilers and machinery, scientific and electrical instruments, copper, woollen manufactures, coffee, and fish. In 1913 the value of the wheat imports was 406,000,000 lire, while the local raw silk was supplemented by the import of over 90,000,000 lire worth, mainly from the Far East. The total imports in 1913 amounted to 3,637,000,000 lire.

Germany supplies 17 per cent. of the imports, Britain nearly 16 per cent., and the United States about 14 per cent., in all cases the imports to Italy being far in excess of the goods sent in return. The next most important sources of imports are Austria-Hungary, France, and Russia.

The position of Italy is a favourable one for commerce. In touch through the Alpine tunnels with the Great Powers of Continental Europe, it is connected with the Atlantic and Indian Oceans by the Strait of Gibraltar and the Suez Canal. Though it cannot be expected to attain the preponderant part which it played in mediæval commerce, its economic development and commercial expansion are both assured.

Economic Divisions of France. The three mountain areas of the Pyrenees, Central Plateau, and Alps are of small economic importance compared with the three lowland areas, southern, western, and northern, each of which touches a different sea. [See pages 1477-9, where a full description will be found.] Nearly 42 per cent. of working people are farmers or foresters, 29 per cent. are engaged in manufacturing industries, 14 per cent. in trade and transport.

The southern lowlands of Languedoc and Provence face the Mediterranean, and belong to the Mediterranean type of country. Wheat and maize and lucerne are grown in the fields, but olive groves and vineyards are more important, and on the hillsides the mulberry flourishes and silkworms are reared. Silk weaving is carried on chiefly at Lyon on the Rhone, near the St. Etienne coalfield, where St. Etienne is noted for silk ribbons, but spinning is common through all the southern region of France. Marseilles is famous for soap, candles, and other works depending on copra, palm oil, and other tropical produce brought by its fleet of merchant ships from warmer lands. More wine is produced here than in any other division of France, and much of it is shipped at Cette.

The Western Lowlands and the Central Highlands. The western lowlands of the Garonne basin produce much wine (clarets), especially round the Gironde estuary, where Bordeaux is the port and chief commercial centre. Maize is still an important cereal. Throughout this area, fruit-preserving, especially of plums, is important. At Bordeaux, colonial produce, especially sugar, is prepared for the market. The central highlands support large flocks of sheep and herds of cattle, but agriculture is important in the fertile plains of the Loire and the Allier. Vineyards are found all round the margins on terraced hillsides facing the south, especially on the limestone heights of the Côte d'Or, which link the Central Plateau to the Vosges. Here the wines of Burgundy are made. The chief centres are Dijon, Beaune, and Macon. Small coal and iron fields round the margin give rise to numerous small industrial centres. The metal works of Le Creuzot and St. Etienne are the most important, but minor smelting and machine-making centres are in the Nivernais, Alais, and Rouergue. Woollens are important in Languedoc, round Bédarieux, and porcelains round Limoges.

Northern and Eastern France. The northern lowlands are mainly in the Seine basin, and they may be considered to extend westwards down the Loire to the Bay of Biscay, northwards through the low hills of Picardy and Artois, and eastwards across the heights bordering the Meuse and the Moselle. This is the centre of wheat and beet growing. Apple orchards and cider become important in the north. Vineyards and wines, including sparkling wines, are found in the south, in the Champagne and Loire districts.

There are four great industrial areas in Northern and Eastern France: (1) The Parisian district, making *objets de luxe*, pottery, paper, etc.; (2) the lower Seine, where English coal, American cotton, and Argentine wool can be brought cheaply to Rouen (cotton) and Elbeuf (woollens); (3) the eastern industrial area supplied with coal from the Saar fields, making iron and steel and cotton; (4) the northern coalfield, with its cottons, linens, and woollens made at Lille, Tourcoing, Roubaix, Valenciennes, Reims, and other centres, numerous iron and steel works, and many sugar factories, most numerous in the western margin, where most sugar beet is grown. Dunkirk is the outlet for the region, which is intersected by a good canal system running to Paris.

French Trade. The table given below shows generally the chief divisions of French commerce and their values during four successive years (a franc = 9¾d).

	Imports (1,000,000 francs)				Exports (1,000,000 francs)			
	1910	1911	1912	1913	1910	1911	1912	1913
Food products	1,400	2,025	1,800	1,900	850	725	825	82 5
Raw products	4,350	4,525	4,825	4,925	1,950	1,825	1,925	1,875
Manufactured goods	1,400	1,525	1,600	1,675	3,425	3,500	3,450	3,600
Total	7,150	8,075	8,225	8,500	6,225	6,050	6,200	6,300

From such a table we notice the variations from year to year, which it is not possible to analyse in the brief space at our disposal here. This, however, warns us to use mean values as much as possible. Further, we notice how France exports almost as much food products as it imports, and in this respect it differs from other industrial countries

of Western Europe. A third point is that both imports and exports of manufactured goods are increasing—a sign of healthy development.

French exports in 1913 consisted of textiles, 15 per cent.: silk, 5·9 per cent.; woollens, 3·3 per cent.; and cottons, 5·8 per cent., formed the most important class of exports. The fine French workmanship and taste ensure a market for highly priced goods. Raw wool and yarn, 4·6 per cent., raw silk and yarn, 2·5 per cent., are both important. Wine, 3·1 per cent., is the chief alimentary product; skins and furs (5 per cent.), automobiles (3·4 per cent.), Paris goods (3 per cent.), and metal goods (2 per cent.) come next.

Britain takes 21·5 per cent. of these exports (largely silk and woollen goods, wine, sugar, butter, leather, carriages, clothes, and cotton goods), Belgium 16·4 per cent., Germany 12·7 per cent., Algeria 8·1 per cent., the United States and Switzerland each 6 per cent. The United Kingdom is thus by far the best customer of France.

French Imports. Raw wool, 8·2 per cent.; cereals, 7·2 per cent., and raw cotton, 6·3 per cent., are among the principal imports. The lack of coal is made up by importation of coal and coke, in decreasing quantities, but still amounting to 6·7 per cent. of the total imports. Machinery, 3·8 per cent.; wine, 3·2 per cent.; hides and furs, 2·7 per cent.; coffee, 2·6 per cent.; copper, 2·4 per cent.; rubber, 2·3 per cent., and timber, 2·2 per cent., are the next items.

Britain furnishes 13·3 per cent. of the imports to France, the principal items being coal, machinery, woollen and cotton goods and yarn, and iron and steel. Germany supplies 12·6 per cent. and the United States 10·2 per cent. of the imports. Next in order are Belgium, 6·7 per cent.; Russia, 5·4 per cent.; Argentina, 4·6 per cent., and Algeria nearly 4 per cent.

British trade is thus by far the most important for France, then that of Germany and the United States, showing that countries well developed economically have very large trade with each other.

The French transit trade is considerable. The general exports for 1912 were worth 8,823,000,000 francs, those of French produce, 6,212,000,000, a difference of 2,611,000,000, or nearly 30 per cent. of the export trade. The favourable position of France in the Mediterranean and Atlantic and its contiguity to the great European States explain this trade.

The Belgian Industrial Area. The Belgian industrial area is a continuation of that of Northern France. It is especially famous for linen made from local and imported flax (at Ghent, Tournai, and Courtrai), woollens (at Verviers) from the Ardennes, as well as imported wool, and round Liége for steel and engineering works near the rich ironfields of the Ardennes and the zinc of Vieille Montagne. Lace is made at several towns (Mechlin, Brussels), and is still a considerable home industry, while at Antwerp sugar is refined, and beer and spirits are made.

Belgian Exports and Imports. The trade of Belgium presents many contrasts with that of France. It has not the same variety of agricultural produce, and the country is not nearly as self-supporting. Its rich coalfields, on the other hand, yield more than enough for home use. Its transit trade is even greater than that of France is. On the average of the last five years it forms 41 per cent. of the export trade of 5,518,000,000 francs.

Antwerp is one of the great wheat ports of the world. The wheat is distributed by rail, and also by water. It is towed in barges up the Rhine, even as high up as Strassburg. Some may even be sent to Strassburg by such a roundabout way as by the Meuse, and the Rhine and Main Canal, at a higher cost, and taking much longer time. As it saves the Strassburg merchant the cost of warehousing, this route is taken by part of the wheat.

Of the special export trade of 3,576,000,000 francs in 1913, wool formed 9·7 per cent., iron and steel 7 per cent., flax and yarn 6·9 per cent., hides 3·1 per cent., rubber (from the Congo) 3 per cent., while railway and tramway cars, chemical products, and zinc each formed 2·6 per cent. of the outgoing trade. Germany takes over 25 per cent., France 19 per cent., the United Kingdom 15 per cent., the Netherlands 9·4 per cent., and the United States only 3 per cent. of the exports.

Belgian imports for home use are valued at 4,583,000,000 francs. Wool (9·1 per cent.) and wheat (8·7 per cent.) are the principal imports, being followed by cotton (4·6 per cent.), hides (4·2 per cent.), seeds, coal, rubber, and chemical products each between 3 and 4 per cent., building wood, maize, machinery, and flax, each between 2 and 3 per cent.

Most imports come from France, over 18 per cent.; Germany, 14·2 per cent, and Britain over 10 per cent.; next in order are the United States, with 8 per cent.; the Netherlands, with 7 per cent.; Argentina, with 6 per cent.; Russia and India each with over 5 per cent. of the total imports.

Switzerland, the German Customs Union, and the Netherlands. The Central European countries have not the advantage of France in position, although in the sheltered valleys of the south the vine comes to perfection. Although Alpine tunnels and the Rhone valley afford routes to the Mediterranean, still most of the commerce finds its way north to the Rhine, Weser, Elbe, and Oder ports.

The Swiss and South German farmers cultivate maize, wheat, flax, hops, chicory, and tobacco on the richer lower plains, and barley, oats, and rye on poorer soils and higher fields. The terraced lower sunny slopes of the hills are covered with vines and the rest with forest, up to the level of Alpine meadows, above which comes the snow line in Switzerland.

The North German and Dutch plains are not suited for maize, and even wheat is not much cultivated. Towards the east and south-east rye becomes the most important crop. Potatoes, from which spirit is distilled, are abundant in the middle Elbe and all of the Oder basins, and sugar beet is a most valuable crop in Silesia and the area between the middle Elbe and Weser.

The Swiss Industrial Area. An important industrial area lies in the northern plateau of Switzerland, between the Alps and the Jura. Though hampered by an absence of coal, Swiss energy and education have developed great industrial prosperity, which is expanding with the increased utilisation of the abundant water power converted into electricity. Engineering works are important in the great towns of the north, especially at Zürich and Winterthur (locomotives). Cottons are made at St. Gallen and Zurich, and silks at Zürich and Basel. The watch trade is commonest in the south-west round Chaux-des-Fonds, Le Locle, and Geneva.

Swiss Trade. Switzerland exported 1,357,000,000 francs' worth of goods in 1912, and over

1,375,000,000 francs in 1913. Its manufactures, silks (21 per cent.), cottons (20 per cent.), clocks and watches (13 per cent.), and its animal food substances, as cheese, condensed milk, etc. (9·3 per cent.), are sent not merely to adjacent countries but over the seas. While Germany takes 23·6 per cent., Britain takes over 17·7 per cent., France 10·5 per cent., and the United States 10·3 per cent. of the exports.

Swiss imports in 1912 amounted to 1,979,000,000 francs, and in 1913 to 1,925,000,000. Switzerland has to import cereals for its industrial population (12·7 per cent.), while silk and cotton goods, minerals, colonial produce, and woollen goods form the next important items.

Germany (34 per cent.), France (19·8 per cent.), Italy (10 per cent.), Austria-Hungary and Britain (6 per cent.), and the United States (4·3 per cent.) supply the bulk of these commodities.

The South German Industrial Areas. The industrial areas in South Germany are in small groups. The only coalfield is that of the Saar valley, where ironworks are important, as well as in the Grand Duchy of Luxemburg. The iron ores east of Nürnberg supply material for the other smelting works. Engineering is important in the capitals of the different states and in other large towns. Cotton manufacturing is the most important textile industry. Chemical works of great importance exist in the northern part of this area.

Silesia and Saxony. The Silesian industrial area is near rich fields of bituminous and of brown coal. Iron industries are common near the former, at Gleiwitz, Königshütte. Engineering works exist in the larger towns, such as Breslau and Liegnitz. The local flax and wool make linen and woollen manufactures important all along the base of the Sudetes. Cotton is spun and woven at Breslau, Glatz, and Görlitz. Sugar is extracted from sugar beet at Breslau and other centres.

The Saxon industrial area has important coal, iron, and other metalliferous deposits. Freiburg is the chief mining centre. Chemnitz, Dresden, Leipzig, and all the larger towns have engineering works. Local wool makes the fabrication of woollen goods very important. As Saxony is in closer touch than Silesia with the oceanic routes by the Elbe and Hamburg, cotton manufacturing is much more important in Saxony. The potteries of Meissen (Dresden ware) and the book trade of Leipzig are special industries of this region. The salt of Halle, Stassfurt, and other centres gives rise to chemical works.

North German Industries. The industries of the North German plain consist mainly of those which elaborate agricultural produce. The most important is the preparation of sugar from sugar beet, especially between the Elbe and Weser. Berlin has the furniture, clothing, and other manufactures of a great capital, and it possesses the great advantage of being reached both by water and by rail. Hamburg may be regarded as the North Sea port of Berlin, and Stettin its Baltic seaport.

Westphalia and the Rhineland. The Westphalian and Rhineland industrial area is the most important of all. Rich in coal and iron, it has the great Krupp works at Essen, the hardware of Remscheid, and ironworks at all the chief centres, Aachen, Cöln (Cologne), Düsseldorf, Dortmund. Woollens, silks, and cottons are important manufactures.

German Exports and Imports. The German Customs Union, or Zollverein, includes Luxemburg. In 1912 the special exports were valued at 9,098,000,000 marks (1 mark equals 1 shilling), and in 1913 at 9,912,000,000 marks. Base metals and their manufactures (19·2 per cent.), agricultural products and foodstuffs (17·4 per cent.), and textiles (15 per cent.) were the most important exports in 1913. Next followed machinery and electrotechnical goods (11·5 per cent.), chemicals and drugs (9·6 per cent.), raw minerals (8·7 per cent.), and leather and leather goods (5·5 per cent.).

Britain takes 13 per cent. of the German exports, and Austria-Hungary takes 11·5 per cent.; the United States, France, and the Russian Empire each receive between 7 and 8 per cent., the Netherlands 6·7 per cent., Switzerland 5·7 per cent., Italy 4·4 per cent., and the Argentine Republic 2·6 per cent.

The German imports were valued at 11,016,000,000 marks in 1912, and 10,695,000,000 in 1913. Unlike France, Germany cannot feed its people on its own produce. Hence 66 per cent. of the imports consist of agricultural products and foodstuffs. Raw minerals form 10 per cent., textiles 7·5 per cent. and metals and manufactures 6·5 per cent. The food sent from the United States makes it the largest source of German imports, sending 14·4 per cent. of the total; from the Russian Empire 13·8 per cent. are obtained, while Britain and Austria-Hungary each supply about 7½ per cent., being followed by France (5 per cent.), India (4·8 per cent.), and Argentina (4 per cent.).

The Netherlands. Holland has little mineral wealth. It can import coal cheaply across the North Sea. It is essentially, however, an agricultural and commercial country, the industrial developments being mainly in the elaboration of produce from the rich Dutch colonies. Sugar and cacao are among the most important.

Dutch trade of home produce or for home use was valued in 1912 at 3,113,000,000 guilders exports, and 3,613,000,000 guilders imports (12 guilders equal £1). The following table shows the principal articles in the foreign trade in 1911 and 1912:

	Imports, 1000 gl.	
	1911	1912
Cereals and flour	573,630	518,771
Iron and steel	422,484	311,734
Textiles, raw and manufactured	126,788	199,866
Copper	194,277	169,860
Wood	107,288	126,347
Coal	113,560	125,838
Rice	100,457	99,576
	Exports, 1000 gl.	
	1911	1912
Cereals and flour	357,409	383,300
Iron and steel	296,040	238,849
Textiles, raw and manufactured	128,199	161,343
Copper	174,508	151,603
Paper	80,782	86,301
Sugar	76,166	85,523
Wood	67,571	65,314
Rice	64,879	60,229
Margarine	48,718	59,885

Of the Dutch exports, 48·5 per cent. go to Germany, 19·4 per cent. to Britain, 11·9 per cent. to Belgium, and between 4 and 5 per cent. to the Dutch East Indies and to the United States. Germany supplies over 28 per cent. of the imports to the Netherlands, the Dutch East Indies 13·7 per cent., the United States and Great Britain about 10 per cent., Belgium 9·5 per cent., and Russia over 8 per cent. In consequence of its position, Holland carries on an extensive transit trade, and it is not possible to analyse our trade with that country from our own trade returns, as much of it is really trade with Germany which passes through Holland.

The Kodak and the Film. Choosing a Subject. Focussing. The Stops. Exposure. Tank Development. Daylight and Gaslight Printing. Mounting.

FILM PHOTOGRAPHY

We all want to make pictures. The picture-making instinct is far older than the wish to communicate by means of writing, and has not the same logical and utilitarian aim. Only a small proportion of people have the time or the patience to cultivate this inborn need of making pictures, but the desire remains; and half the visitors to a gallery of paintings come away with the unspoken thought: "If only I, too, could put on paper or canvas some delineation of the world in which I move!"

And the nineteenth century saw the arrival of an invention which put picture-making within the power of all. Science has given us the camera, wherewith we draw not by means of a pencil but by means of rays of light; and while the invention of the railway, the telegraph, and the aeroplane may be more revolutionary in their results, it is hardly an exaggeration to claim that none of them make so direct and popular an appeal to a mere human instinct as does photography.

That mysterious instinct was, and is, a sound and wholesome one; and, now that countless people have been able to indulge it, they find that it has brought its own reward.

The Camera an Educator. It is actually the case that the camera trains its owner's observative faculties. Give a boy a camera, even the most toy-like, and at the end of six months' amusement with it his eyes will be amazingly sharpened. The camera is an educator unawares. It is an educator in spite of the circumstance that its user need know nothing about photography in the scientific sense. The pedant may mourn that photography has been made too easy, and that the watchword "Press the Button" saw the end of its educative value. It is a false presumption. "Press the Button" is no mere catch-phrase in excuse of laziness; it is the announcement that a gate of knowledge and happiness once permanently and inexorably closed to the majority of mankind is now open to all.

Those who had the time and the patience and the skill have never, since civilisation began, been prevented from entering that gate, and when photography first appeared there were plenty of enthusiasts willing to devote themselves to its toilsome practice. Today, if we wish, that devotion is unnecessary; we reap the fruits of previous workers in the shape of an extraordinary simplification of all apparatus and processes.

A firm belief in the value of this simplification governs the policy of the present chapter. It is purposely un-"scientific." A little guidance the photographer must have before he can make proper use of his camera; that guidance will here be set forth, in non-technical language. It concerns the photography of Everyman, not the photography of the specialist. The requirements of the latter are only briefly touched upon, inasmuch as whole libraries of learned volumes are already at his disposal, while the needs of him who is called the mere snapshotter—in other words, of nine hundred and ninety-nine camera-owners out of a thousand—are curiously neglected. At the Kodak, which is perhaps the best-known form of hand-camera, and the Kodak method, we may therefore glance first.

The Kodak. The Kodak consists primarily of a light-tight box, with a lens at one end and a sensitive film at the other. The scene at which the camera is aimed is projected, by the lens, on to the film, where certain chemical changes take place. When certain further chemical changes ("development") have taken place, the film displays, upon its surface, a picture of the scene.

Certain Kodaks are actually boxes; certain others present themsleves as boxes which, for the sake of foldability, have collapsible sides—the familiar bellows. As far as mere photograph-making is concerned, it is literally of no importance which type of Kodak the beginner selects. The cheapest will take photographs—and the dearest will take photographs neither better nor worse. Broadly speaking, the dearest have only this advantage—that in a poor light, or with a rapidly moving subject, they can on occasion take photographs when no photography at all is practicable with the cheaper camera. But if the cheaper is usable, the dearer is usable too, and generally with only equal, not superior, effectiveness.

One point should be mentioned here, and that is that many of the Kodak models are now autographic. This means that they take Autographic film—it costs no more than ordinary film—which enables the user to write any notes, such as the date or title of the subject, on the film at the time he takes the picture. This writing then appears on the margin between the pictures when the film is developed, and so becomes a permanent part of the photograph.

Perhaps the first thing to be said about the camera is that it works. Many beginners either blame their cameras for failure, or force camera mechanism which needs no forcing. It must be understood, then, that the various knobs, buttons, and screws with which the Kodak is fitted all have a reason, and all will behave properly if properly handled. No wrenching or forcing whatever is needed to actuate any part of any Kodak. A Kodak is a machine, and works with the smoothness of a machine. Everything "works," and works so beautifully that only gentleness is wanted. Violence will put it out of order. But gentle manipulation is not inconsistent with firmness of manipulation. Removing the back from the folding Kodak should be done by a firm but not twisting grip of the pair of catches. The back comes away as light as a feather, and quite silently. And the roll of film loads into the back of the camera with the same quiet facility. *Read the instructions carefully* is a golden rule; and every camera-vendor agrees that it is a rule sadly neglected.

Fogging the Film. It is not the purpose of these articles to save the beginner from reading makers' instructions, but rather to treat of matters which those instructions omit. We shall therefore take it for granted that the actual loading of a film-cartridge into the Kodak is plain to the student, and shall pass on to remind him that, if light is

going to impress a picture on that film through the lens, it may, if care is not taken, reach the film without first passing through the lens, and impress it in such a way as to make it useless.

Should the spool of film become unwound, light will edge in at the crevices, and what is called "fogging" will ensue. *Fogging* is the spoiling of the sensitive film by light from outside the camera.

When the roll's seal is broken, the roll being in position in its nook in the camera-back, a gentle but firm finger-tip must hold down the outer paper while it is wound off on to the receiver; and the moment the receiver has got a good grip of the end of the paper, the back of the camera should be gently but firmly put into position once more. Now the film is safe, inside the camera; but after the exposure, when it is being taken out of the camera or placed in the winding-box which precedes tank-development, it is again unsafe, and again gentle but firm fingers will keep the spool tightly wound, allowing not too much of its paper to unwind.

This carefulness in avoiding fogging becomes second nature after a very little use of the Kodak, as also the habit of loading and unloading not in full sunshine but in the shade.

The Choice of Subject. Suppose, then, that you have loaded the film into your Kodak, and are ready to take your first picture. What shall be its subject?

Snapshots must be made in daylight, and preferably in sunshine. This is a limitation hardly to be grumbled at when we recollect that, down to the minutest detail, the scene is caught by the film in a tiny fraction of a second. But if photography today consists largely in pressing the button of a Kodak, why are not all snapshots alike, equally irreproachable? And not only is there a wide gulf between the bad photograph and the good one. Even the good ones are strangely dissimilar.

This is because photography, though achieved with the aid of a machine, is not mechanical. Snapshots all differ, for the obvious reason that the button may be pressed at an infinite number of different moments while the Kodak is aimed at an infinite number of different subjects in an infinite number of different circumstances. All these factors are dependent on the personal taste of the user of the Kodak; not one of them on the Kodak itself. That is why a lesson in the art or hobby of photography need have no concern, strange though it may seem, with the choice of camera, lens, or film, while treating in some detail with the use of each and all of them.

The beginner must grasp that it is at the outset more profitable for him to recognise the limitations of photography than to waste film by snapping here and there in the hope of luck producing results. There is no luck in the matter. When a photograph turns out badly, or does not appear on the film at all, it is the photographer's fault, and generally it will be found he has attempted something unphotographable.

We must examine, therefore, the table of lights and subjects sent out with the film, and remember that, while snapshotting in dull weather is not impossible, bright weather should preferably be chosen for the first attempts, and these must not be made either before sunrise or at dusk, even when the sky, under these conditions, looks wonderfully bright to the eye. Let us therefore set out to make our first exposure on a sunny day, preferably in summer; and although a street-scene, a race, or other subject in rapid movement is quite within the scope of the camera, let us begin with a non-moving subject. We shall find it easier and we shall not be flurried. We shall have plenty of time to think of the various factors which govern the success of our first picture. Let us imagine ourselves going out into the garden to make a portrait of a friend or relative seated there—not "posed" and not "being photographed," but just enjoying the warmth and reading a novel.

Taking a Snapshot. To get his full figure only, we shall have to stand quite close up to him—a mere six or eight feet away—whereas to get him full-length, with some of the surrounding garden visible on each side of him, we may stand farther off—say, fifteen feet distant. It is upon this circumstance that the whole of the procedure known as *focussing* depends.

Focussing. The booklet of instructions supplied with the Kodak draws your attention to the existence of the focussing-scale, which is visible on the right-hand side of the baseboard of the instrument when opened. (We allude, for the moment, to the folding Kodaks which take pictures $4\frac{1}{4}$ in. by $3\frac{1}{4}$ in., postcard size, and $6\frac{1}{2}$ in. by $4\frac{1}{4}$ in.; the small-size non-focussing Kodaks will be dealt with later.) This scale is marked with figures which denote feet, and refer to the number of feet of distance at which the subject is from the camera: 6 ft., 8 ft., 10 ft., 15 ft., 25 ft., and 100 ft. The front of the Kodak, carrying the lens, can be pulled out and fixed opposite any of these feet-figures. But it must be opposite the correct feet-figure, otherwise you will not get what is called a sharp picture. If, for example, you snapshot your friend when he is seated 10 ft. away, and your focussing-scale is set at the 25 ft. mark, the portrait will be blurred; but perhaps, beyond the sitter's shoulder, you may catch a glimpse, in the picture, of a tree which happened to be 25 ft. away, and it is not blurred: on the contrary, its trunk and its every leaf is distinct, clear-cut, and sparkling.

And the portrait would have been just as disappointing if the sitter had been 25 ft. away and you had set the scale at 10 ft. Therefore, we must learn to judge distances at sight, otherwise we shall always be setting the scale wrongly, and making pictures in which the principal object is blurred and some other quite unimportant object, nearer or farther off than the principal one, is needlessly sharply rendered.

Judging Distance. Standing a little way from your friend, measure with your eye the distance from the base of his chair to your own boot-toes. It pays to train yourself from the start to estimate distances accurately. Having guessed the distance from yourself to your friend, check your guess by measurement. The simplest form of measurement (rough and ready, but accurate enough) is to stride the distance, allowing 3 ft. for each step. The really keen amateur, determined to cultivate a strictly accurate mental measuring-tape, will find that the preliminary employment of an actual measuring-tape is repaying.

Let us suppose that in this instance, as we want to take a full-length portrait and include in the picture some suggestion of the surrounding garden, we stand 15 ft. away from the sitter, and set the focussing-scale accordingly. You will observe that had you intended to take the sitter at 10 or 6 ft. distance, the front of the camera would have had to be pulled farther out from the back. The nearer the object to be photographed, the farther must the

lens be from the film; but in practice we shall seldom, if ever, require to take anything closer than 6 ft. On the other hand, if the principal object in our picture, whether a figure or otherwise, be 100 ft. distant or more, it is (in practically all cameras with which the average amateur would be likely to deal) at what is called the *infinity point* of the lens. When set at the 100 ft. mark on the scale, the lens need be racked no further inwards. Everything at or about 100 ft. distant in the picture, and everything beyond, will be sharp.

Fixed-focus Instruments. In some smaller Kodaks the front, containing the lens, is so arranged that it either will not move at all or becomes automatically fixed at a certain point. No focussing is required. Provided the nearest object in the picture is not nearer to the camera than a given distance (a distance which, in the smallest Kodaks, is quite a short one), everything in the picture will be sharp. Kodaks of this type are called *fixed-focus* instruments, and the beginner will find them easy to use, no mental measuring, as described above, being demanded. For purely optical and scientific reasons, which need not be enlarged upon here, it is impracticable to make a good fixed-focus camera to take pictures larger than "quarter-plate" (that is, 4¼ in. by 3¼ in.); and the fixed-focus lens, though much excellent work is done with it, has certain drawbacks, apart from the smallness of the picture it takes, which cause the more experienced amateur to prefer the focussing lens.

To return to the taking of our portrait. We have focussed on the sitter. Therefore we know that he will appear sharp on the film. What else have we to think of before we make our exposure? What other precautions against failure have we to remember? There are four:

Subject, Light, Stop, and Duration of Exposure.

The subject we have already chosen; also the light, which is bright sunshine—that is to say, the best light which occurs in Nature. Remains, first, the stop, or aperture; and, second, the duration of exposure.

The Stop and its Manipulation. The *stop*, or *aperture*, is the hole through which the light reaches the film. It is really a window, rather than a hole, and the glass of the window is the lens. But the size of the hole is described as such-and-such a stop, or aperture, and that size can be decreased or increased within certain limits, though the lens remains the same size. In this way, by enlarging or reducing the size of the stop, the photographer can regulate the amount of light that enters his camera through the lens.

In the box-form Kodaks two or three different-sized holes are arranged on a plate, which can be moved so that one hole or another comes opposite the lens window; in the larger folding Kodaks, with which we are mainly concerned, the hole is formed of a device called an *Iris diaphragm*.

Examine the front of your camera, and under the lens you will see a little pointer, which can be pushed around a semicircular dial. Marked on this dial are the figures F/8, 11, 16, 22, 32, and 45; and on others, especially Kodaks, a different and perhaps simpler system of numbering is adopted, and the exact meaning of these numbers is explained in the instructions given with each Kodak. Whatever system is adopted, these numbers indicate the size of different stops. Although with the shutter closed you cannot see any change in the lens when you move round that pointer, a change is actually taking place, and can be observed if the shutter is set at "Time" and opened. What is happening as you move the pointer of the Iris diaphragm round is this: a kind of metal mouth, which at F/6 or F/8 is wide agape, gradually closes, until at F/32 or F/45 it is a mere speck of an aperture. This mouth is the entrance through which the flash of light has to dart in order to impress the picture on the film when we press the button. And it is clear that far less light gets through the mouth when it is small than when it is wide open. So, remembering what we said about the necessity of light for photographing, we perceive that, if more light (as is obviously the case) gets through the lens when the stop is, say, F/8 than when it is F/45, a shorter exposure will be allowable for a picture taken with the former (or larger) stop than with the latter or smaller. And as short exposures are very desirable—for we want to snapshot, not to be bothered with a tripod and time exposures—we deduce that the F/8 or F/6 is the stop which we should use.

Why, then, is any other stop provided? If all our snapshots are to be taken at F/6 or F/8, what is the use of making the Iris diaphragm to close up to a smaller aperture at all? The beginner need not concern himself with any stop smaller than F/11, or perhaps even F/16. These demand time exposures, and belong to advanced photography. The worker to whom such small stops would be of use is beyond the requirements of the instruction here to be conveyed. But the larger stops—F/11, for instance—are on occasions useful even in snapshotting. When are they useful, and what is their function?

Securing a Sharp Picture. To begin with, let it be laid down that we should do without any stop smaller than the largest if we can; and, secondly, we may only use as small a stop as F/11 in a very bright light, and for an open subject. We might, for example, use F/11, or even perhaps F/16, on a brilliant day at the seaside; and although only a quarter as much light gets through the lens at F/16 as gets through at F/8, there would still be sufficient light to take a picture, because by the sea there is far more light than inland. Still, however, we have not explained why we should not permanently use F/8 or F/6, as the case may be. And to answer this it will be necessary to make a statement, and then leave it unexplained, because there is no space here to expound the reason for it. The statement is this: the smaller the stop, the sharper will the picture be.

But if we have focussed sharply on our principal object, how can it be made any sharper than sharpness? It is not. But the neighbouring objects can be made sharper. Our friend in the chair on the lawn will be sharp on the film if we take him at 15 ft. distance, and set the scale accordingly. But the grass a little nearer the camera, and the trees some way behind the sitter's chair, will be blurred. By closing the Iris diaphragm to F/11 or F/16 we sharpen up that nearer grass and those distant trees, and so get a picture which is sharp all over, not only sharp at that section of it which happens to be just about 15 ft. from the camera.

Duration of Exposure. Suppose we want this sharpness, though, we must pay for it by increasing the duration of exposure. And duration of exposure was last of the quartette of factors which we decided we had to weigh carefully before pressing the button. The beginner may reply that duration of exposure is no affair of his. He only wants one duration of exposure—namely, the

snapshot. But there are snapshots and snapshots; and if in the smaller and more primitive Kodaks to which we have referred—which reduce the art of photography to its simplest elements—exposures of only one duration, or perhaps at most two different durations, are allowable, in the somewhat larger Kodak here postulated quite a number of exposures of different duration may be made, as the fitment called the shutter will presently prove in response to our inspection.

ARCHITECTURE WITH A KODAK—THE TOWN HALL, OXFORD

The *shutter* is a mechanism for opening and closing the window of the lens.

The book of instructions, and a good look at the shutter, will show you that—quite ignoring all "time" exposures—it is possible to give, for instance, a fiftieth of a second or a hundredth of a second exposure. Both are snapshots, but one is obviously twice as long as the other; and though both are—to the unscientific mind—unthinkably short, they are both long enough to affect the sensitive film very appreciably.

The beginner naturally wants to know which exposure he shall give, and this is precisely one of those questions which cannot be answered offhand, for its answer depends on several circumstances—the subject, the amount of light, and the stop to be used. The whole four are inextricably interlinked in our calculations; it is impossible and useless to consider one without its partners. With a bright light, fully flooding the subject, and with a large stop, we can give a fast—for instance, a hundredth of a second—exposure; with a bright light and a smaller stop we must lengthen the exposure; with a bright light and a still smaller stop we must give an even longer exposure, and so on. Each depends on the others.

The types of subject, light, stop, and exposure, all in their due relationship, are admirably set forth upon leaflets and in handbooks which every amateur will obtain with his Kodak, and with every spool of film for use therein. Here—after mentioning the stops and possible exposures as above—we find subjects divided into "landscape," "marine," "street scene," "outdoor" group, and others; and light into "brilliant," "cloudy," and "dull." These we shall for the present ignore, concerning ourselves only with the actual experimental subject which is to furnish us with out first essay in photography.

Our garden portrait—what exposure shall we give it? Supposing that our stop is F/8, that we are 15 ft. distant from the sitter, and that the sun is shining on him from that part of the sky which is more or less behind the shoulder of the photographer, it is safe to say that a fiftieth of a second's exposure will give a good result. Should there be white clouds in the sky, so that the sunshine is a trifle diffused, we may allow for this, and give a twenty-fifth of a second. We set the shutter accordingly, doing so as in its instructions. And we are now ready to aim the camera.

Aiming the Camera. Merely straight aiming is, of course, managed by means of the little apparatus known as the *finder*—that miniature camera on the side or top of the real camera in whose glass we may see a tiny picture of the scene which we intend to photograph. Looking down into the finder, we take aim in such a way that our sitter in his chair is somewhere about the middle of the finder's miniature—when the image of him will fall at the middle of the film when the button is pressed. The finder, then, is really a sighting apparatus; it helps

us to aim straight and also to get the scene level, for it is important to hold the Kodak level, though a very little tilting upward or downward—in a portrait—is of no consequence. In aiming the camera, too, we must take pains to hold it quite steadily. It is held against the body with both hands, and the photographer must momentarily hold his breath when he is pressing the button.

Releasing the Shutter. We have spoken throughout of pressing the button, because this is the popular phrase; actually, the releasing of the shutter is done either with a squeeze-bulb, a patent flexible wire release, or a trigger. Different types of Kodak have different devices; their function is all the same—to set off the shutter. All that the photographer must remember is that, whatever release he uses, he must press it gently but firmly, not with a jerk or hard push.

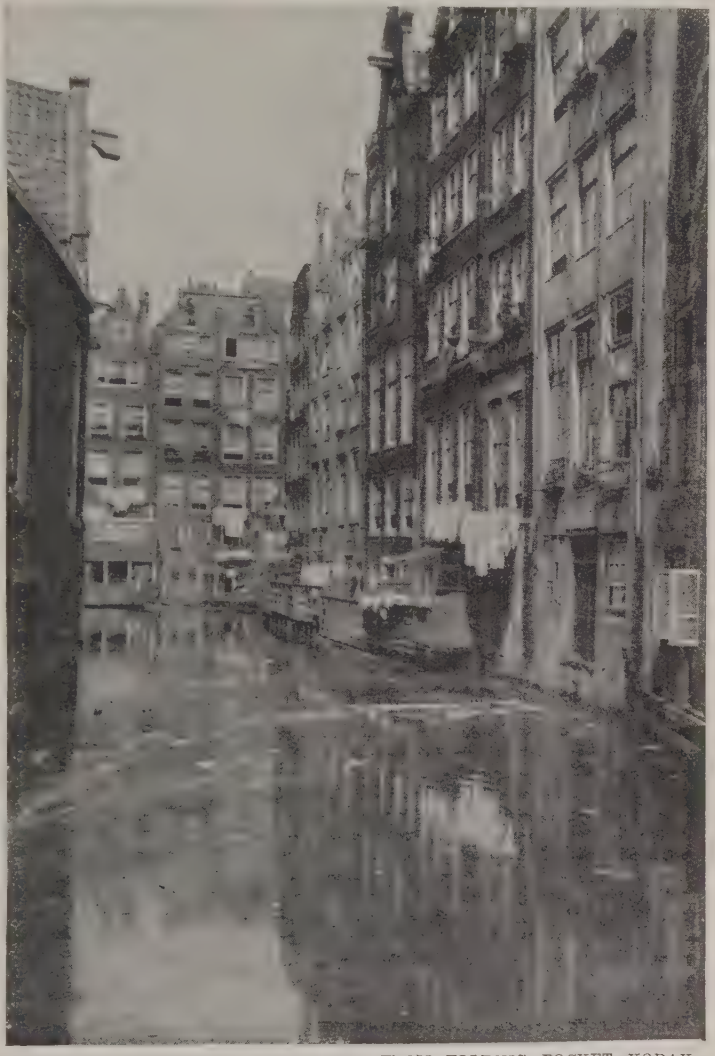
Ascertain that the film is in position by examining the little red window on which the number 1 of the film appears, see that the stop is the one chosen, set the shutter, aim the camera by observing the picture in the finder, hold camera and body rigidly and hold the breath, then set off the shutter release.

The portrait is taken.

Over-expose rather than Under-expose. We have now reached the first stage in the making of a picture by photography; we have snapped a portrait, or, in the more serious phrase, we have made an exposure.

The photograph is by this time either a good one or a bad one. Nothing can alter it now for the better, and nothing except a mistake in after-treatment, or deliberate mishandling, can alter it for the worse. All photographs must be rightly exposed in the first instance. It is true that a slight deviation from the theoretically "correct" exposure may make no very visible difference in the long run. To the ordinary amateur it is of no practical consequence, for example, if the "correct" exposure happens to be a thirtieth of a second, and he actually gives either a twenty-fifth or a fiftieth. Given that the weather is bright, and the subject an average one, there will be little difference to be detected, when development is over, between a strip of film which has received a twenty-fifth of a second and a fiftieth. When in doubt as to which of two exposures to give, the cautious amateur will choose the longer, unless his subject be lacking in contrasts of light and shade.

What is called the "latitude" of the film compensates, to a wonderful extent, for slight over or under exposure. Latitude is a characteristic the practical effect of which, as far as we are concerned, is that the various different exposures on a strip of film are all rendered much more nearly correct than if the film, having no latitude, required a certain precise exposure to give you a satisfactory result. Your first picture, for instance, may have a good deal of shadows, the second be in a blaze of sun, the third be a portrait, the fourth a seascape, and so on, and probably each is minutely "incorrect" in its exposure; yet, thanks to the "latitude" of Kodak film, all will turn out equally pleasing. It will be seen that this levelling up, due to latitude, is an essential quality in any film which is to produce tolerable photographs at all, for every photograph, without exception, is a compromise in the matter of exposure. Every photograph, that is to say, contains parts which are well lit and parts which are less well lit.



VIEW IN AMSTERDAM—ENLARGED FROM FOLDING POCKET KODAK

When we have developed our portrait we shall see that the details in the scene at which the camera aimed are all visible to the eye. Yet some of those details must, in the nature of things, have been under-exposed and some of them must have been over-exposed. Our sitter was perhaps garbed in a dark suit, wore a white collar, and cast a shadow on the ground. A moment's thought will show that, if minutely accurate exposure were demanded, we should not be able to take all those things simultaneously. More light is reflected from the white collar than from the suit, and more, perhaps, from the suit than from that part of the grass below the sitter's chair which is in shadow. And, bright though the light reflected from the white collar may look to the eye, it is nothing compared with the brightness of the patch of sky which we have included in our picture above the sitter's head. It is probably no exaggeration to say that a thousandth of a second would not have been too short an exposure for the sky; and if a two hundred and fiftieth of a second was correct for the linen collar, we may guess that ten times as long would be necessary for the suit, and longer still for the shadow.

We have chosen a medium, striking a kind of average for the whole; and a twenty-fifth or fiftieth of a second has, as an inspection of the developed film shows us, actually managed to capture all, or virtually all, the details, in every grade from absolute white to deepest shade. This capacity, as has been said, is due to the latitude of the film. Nevertheless, there is one fault for which even this, the best sensitive material, cannot compensate, and that is severe under-exposure.

Under-exposure a Grave Error. Under-exposure means that insufficient light has reached the film to impress a picture on it. Only a miracle can develop a picture, or a part of a picture, which has never reached the film. Hence the recommendation to err on the side of over rather than on the side of under exposure.

In snapshotting—by which is meant instantaneous photography, as contrasted with time-exposure photography—over-exposure is a very rare fault; a fault, therefore, which may generally be risked with impunity if there is any doubt in the mind of the snapshotter. An old maxim of photography says: "Expose for the shadows, and let the high-lights take care of themselves." This proverb was coined in an era when plates had but little latitude and films were unknown, but it still contains a germ of valuable sense. Unless his picture is one possessing no shadow parts at all (and such scenes are very rare in Nature, except at the open sea), his bright parts will—thanks to latitude—be none the worse of the over-exposure which they have suffered, and its dark parts will be all the better, if, indeed, they have been over-exposed at all.

The object of this short digression on the subject of over and under exposure, and the boon of latitude which modern film-makers now offer us, is to give weight to the suggestion that we might now, with profit, expose the remainder of our strip of film on the same portrait, but giving different exposures. For before proceeding to the task of development we may as well use up the whole of our film-cartridge instructively.

Supposing the spool of film is sufficient for six pictures, the five remaining ones should be snapped on the same portrait over again, giving it two or three of the different exposures which the shutter allows of, and taking it from different distances. This procedure will make the photographer familiar both with his shutter and with the use of the focussing-scale. Naturally, if anything is to be learnt from these variations, a careful record must be kept of the distance, stop, light, and exposure for each picture.

Winding off the Film. Without closing the camera, if it be of the folding type, turn it over, lens downward, and at its back you will notice a little round red patch, resembling a seal, the size of a threepenny-bit. This is transparent, and is really a tiny red window, through which you can see the back of the long strip of paper in which the sensitive film is wound. At present the number "1" is visible through the window; by slowly and carefully turning the winder the number "1" is caused to disappear, and presently "2" takes its place. A fresh strip of sensitive material is now in position, and we may proceed to make our second exposure.

There are trifling differences in procedure involved in the use of the various patterns of Kodak, but the used film should be wound off immediately after each exposure, or it may be forgotten, and two pictures will be taken on the same piece of film, the consequence being that both are spoilt.

Removing the Spool. When the last exposure of the strip has been made, the film and its protective paper are wound off. The spool of paper, with the film safely wrapped up in it, can now be taken out of the camera. The V-shaped loose end of the paper is stuck down, a portion of it having first been folded in, to make a little ridge. By leaving a tiny ridge of folded-in paper, we make the detaching easier when the spool has to be unfastened: the stuck strip can be torn, not cut.

In removing the spool from the camera, prior to sticking its end down, be careful to hold it gently but firmly, preventing any tendency to unroll. If the spool should unroll a little or become loosened, light may get in at its edges, and our pictures will be spoilt. Not until development is over can the film safely be exposed to even the faintest light.

Development. Within the paper-covered spool which we hold in our hand now there is a strip of pictures. In order to make those pictures visible a further chemical change must take place, and this is called development. This second chemical change is brought about by the application, *in total darkness*, of a certain liquid, called the *developer*, to the exposed film. After the photographer has used the developer and applied an intermediate dose of clean water to his film, he will have to immerse it in a second liquid, called the *fixer*. These two substances, the developer and the fixer, he will buy ready-made. They are sold in powder form, and are dissolved in water when needed. The method of dissolving and the quantity of water are both clearly specified on the packages.

Before the invention shortly to be mentioned, it was necessary for every amateur either to do the developing of his photographs at night, or else to set aside in his house a special apartment for the purpose—a so-called *dark-room*. But as the dark-room is now no longer necessary for unwrapping and re-wrapping sensitive material, so it is no longer necessary for developing films. It has been abolished by the invention of the *developing-tank*.

The Developing Tank. The developing tank will have been bought at the same time as the Kodak, and five minutes' study of the tank and of the pictures in the pamphlet which accompanies it will show its principle to the purchaser. The function of the tank, and of the box which goes with it, is to provide a substitute for the dark-

room; to provide, in fact, a miniature dark-room into which the strip of exposed film can be introduced, and there treated with the developer.

Ingenious mechanism was invented to enable the film to be wound off inside the camera and then wound up again for taking out. Similar mechanism is used in connection with the developing-tank. Within a light-tight wooden box the spool of film is wound into a wider tape of quite opaque celluloid (the "apron"), and this packet forms what might be described as a flexible dark-room in itself.

Encased snugly and safely within the encircling walls of this tubular dark-room, our exposures can be lifted out of the winding-box and dropped into another box, a tin one called the "cup," which is already partly filled with developer. The developer rises up around the packet, penetrates into its spiral folds, reaches the film there, and duly develops the pictures—without the photographer having had to touch the film and without any risk of light-rays reaching it.

Now, it is plain that as soon as the rising liquid of developer reaches the film it begins to do its work of development. But how are we to know when it has ended its work, or has done enough developing?

The photographer who has exposed a plate takes it into his dark-room, which is not really dark, but has a lamp which gives a feeble red light. Beneath the gleam of this light he pours developer on to his exposed plate, and, watching it, he can see when the picture has appeared sufficiently and it is time to pour the developer off. But our exposed film is hidden inside its apron, and even the apron itself is hidden inside the developing cup. So we cannot watch it to see when the pictures are finished. If we opened up the apron to have a look at the film we should spoil all our pictures by letting in light, and so causing fogging. The inference is that we must guess the length of time during which the developer must be left to attack the film. In actual practice, however, no guessing is required. We shall know, to the minute, just how long to leave our pictures in the developer.

A COTTAGE IN HUNTINGDONSHIRE—TAKEN WITH A KODAK JUNIOR

The Period of Development. For as in exposure we saw that there was a kind of averaging which made fractional errors negligible, so in development we strike a similar average. It is true that the piece of film which has "seen" most light will develop more quickly than another piece of film which has seen less light. But correct development will strike a balance between them, so that both are as good as human agency could conceivably make them. And correct development, as it happens, is an ideal far easier arrived at than correct exposure. With the tank or "cup," which contains a known amount of liquid, with the developing powders, which contain known quantities of certain chemicals, and with the film, which is of a known sensitiveness, it is possible to announce with absolute precision that any set of exposures of whatever sort must remain in the developing-cup, immersed in the developer, for a given number of minutes; and when the pictures are taken out they will be the best possible to produce by whatever method of development could have been tried.

Be it noted that this mechanical but rigidly scientific system of dark-room-less development depends absolutely for its success on the factors mentioned—namely, the developer, the capacity of the cup, the invariability of the film, and also the temperature of the developing solution—which will be dealt with presently. It is because the two first factors are vital ones that we assumed the necessity of using ready-made developer and a ready-made tank. The scientific chemical staff who make up these developers have adjusted them to an irreproachable perfection of accuracy, and no amateur compounding his own developer could possibly achieve this perfection; further, should he alter the developer, he will certainly alter it for the worse. It is literally the case that the photographer who nowadays makes up his own developer is doing just as uneconomic and—far worse—just as unpractical a thing as if he tried to build his own camera, grind his

own lens, or coat his own sensitive emulsion on strips of celluloid for film.

Temperature of the Developer. The exposed film, then, is to be left in the developer for a perfectly definite given time, and then taken out, with the certainty that the best possible pictures have been developed in spite of the fact that we have not yet had a glimpse of them. What, then, is that definite given time? Here we reach the one variable factor in our calculation. That factor is the temperature of the developer. If the developing liquid is cold it will develop more slowly than if it is warm. Totally cold developer will not develop at all, and very warm developer will spoil the film. We want our developer, then, to be of a certain normal temperature; and the "normal" is 65° F. A little above or a little below will do equally well; but, whether above or below, we must know just what the temperature actually is, and to ascertain this we must use a thermometer. Any thermometer, dipped into the liquid in the developing-cup before the apron-enclosed film is put in, will do, but suitable thermometers are provided by the tank-makers.

With the tank we find a book of instructions which tells us how long, at each temperature, the film should be left to develop. At the normal (65° F) it should be left for *twenty minutes*. At a lower temperature it should be left longer; at a higher temperature it should be left less long. Precisely how long, the temperature-chart will tell us. Do not guess the temperature of your developer. Sometimes you may guess right, but a day will come when you guess wrong, and spoil a strip of exposures. Guessing is not only disrespectful to your materials; it is inexorably punished by the waste of those materials.

The theory of this method of film development has taken some paragraphs to explain, but the fact remains that it is perhaps the simplest of all photographic processes, and certainly one of the most fascinating. Those who have watched friends engaged in the old and messy systems of developing plates will be astonished at the cleanliness, rapidity, and ease which have ensued from the introduction of the Kodak film tank.

When you buy the tank you will find enclosed with it a booklet giving full instructions. Usually, indeed, you need not read it, as most Kodak dealers are keenly interested in their business, and they will develop a spool before you, and so give you all the instruction you will require.

After development, the film has to be fixed. It is best to buy the developing powders made on purpose for the tank, and it is also true with regard to the acid fixing salt which is made for fixing Kodak film.

Your pictures are now before you, but they are in the form of *negatives*. Your friend's portrait shows him with a collar that is nearly black and with boots that are nearly clear film. But before you can get *positives* or ordinary photographs from them, the film must first be *thoroughly* washed to free it from the fixer, and dried. Full directions are given in the instruction books given with both the Kodak and the tank, so space need not be devoted to it here. Printing is the next operation to be dealt with.

Printing by Daylight. We are now at the stage of having got a negative. It is our purpose to turn that negative into a negative of the negative—that is, a positive. We are going, in short, to make a *print*.

The paper on which prints are made is sensitive to light, much as our film was sensitive to light. There are two kinds of printing-paper, which will be fully described, one of them a good deal more sensitive to light than the other. The first, called Velox (which is the best-known gaslight paper), is sufficiently sensitive to be printed by gaslight or other artificial light at night; the second, called Solio (which is the chief brand of P.O.P., or *printing-out paper*), can only be printed by daylight.

For our first experiment in printmaking we shall use P.O.P. Procure at the dealer's a packet of glossy Solio of the same size as the negative, a shilling bottle of combined toning and fixing solution, and a printing-frame with a piece of glass free from all faults such as air-bubbles.

If we take one of these pieces of Solio and put it at the window on a bright day it will presently show its sensitiveness to light by turning black. It will not go black in artificial light, and if the daylight is very faint it will take a long time to go black. The amount of direct daylight reaching the back part of a room, some little distance from the nearest window, is small, so we may open the Solio packet quite safely at the back of any ordinary room, though even there we should not leave pieces of Solio lying about. As soon as we have taken the one piece which we require out of the packet, we should wrap up the remaining ones, and put them back in their envelope.

How the Print is Made. A moment's reflection will show the reader how a positive—a print—is to be made from the negative. If we lay down the piece of Solio behind the negative, and let the light shine through, the Solio will automatically be transformed into a negative of the negative, for more light will reach it through the *shadows* (the transparent parts of the negative) than through the *high-lights* (the opaque or more or less opaque parts).

In our portrait, for instance, we see in the negative that the sitter's white linen collar looks black. Very little light will get through the negative's image of the sitter's collar on to the Solio; consequently that part of the Solio which is under the collar will remain unexposed to light—will remain white. Under the sitter's chair there is a dark shadow, which in the negative is light, almost transparent. A good deal of light will get through this part to the Solio, which will therefore darken, and thus delineate correctly the darkness of the shadow. Throughout the whole scale of multitudinous lights and shades the Solio will capture every gradation, provided the negative contains that gradation, but always in negative—which, as we pointed out, means that the negative of the negative will look to our eyes a positive.

The printing-frame has some resemblance to a picture-frame, opening behind by means of a pair of sliding springs. Unclasping those springs, and taking out the back, we see a piece of glass, on which the film negative can be laid down. Against it the piece of Solio can be laid, the back replaced, and the whole sandwich of glass, film, paper, and back clamped securely. Put down the negative on the glass with the film side—that is, the dark, dull side—face upwards, and the shining side against the glass, first of all seeing that the glass is polished clean. On the negative put the piece of Solio face downwards—that is, with the glossy side against the negative's film or dull side. Now put in the back, and slide the springs home. The printing-frame is now taken to the window, and

put up there, either on the sash or on the sill outside, in such a manner that clear, uninterrupted daylight floods through the front of it, through the glass and the negative, to the Solio behind.

The Treatment of Thin and Dense Negatives. If the negative is a very black-and-white-looking one—a negative in which the dark portions are exceedingly opaque and the other portions very transparent—it is called a contrasty or *hard negative*, and it may be printed in direct sunshine. In this case some little care must be taken to put up the frame at the window (preferably outside the window) so that no shadow falls upon it. The shadow of the window-sash, or of an upstanding tree or steeple or fence rail, falling half across the frame will cause that part to be slower in printing than the rest. The frame should face direct towards the sun, so directly that not even the rebate round the frame casts a shadow along the margin of the glass.

Ordinarily, however, with an average negative the most pleasing results are obtained by printing not in the sun, but in the shade. Not that the printing-frame is to be put in a dark shadow. It should be put out, if possible, on to a window-sill, or some such place, where it can lie, glass upwards, facing the open sky, but not in the direct rays of the sun.

Just how long the printing will take it is impossible to say. In bright weather, or with a *thin* —that is, not very opaque—negative, printing may be complete in a few minutes. In dull weather, or with a *dense*—that is, extra opaque—negative, printing may take hours. Fortunately, it is possible very soon to judge about what the duration of the printing will be. If the light is bright, we may take down the printing-frame a few minutes after we have put it up on the sash or sill, and carry it to the back of the room to examine the Solio. It is not wise to examine the Solio at or near the window, for fear bright light might reach it and fog its picture. If printing has begun, on lifting up one half of the hinged back, and turning back the paper, we shall now see on the paper a more or less faint positive—a picture of the portrait which we took in the garden. If, as is likely, the print is not nearly dark enough, we let it relapse into place again on the negative, close the back, and push home the spring, then putting out the frame into the daylight once more. During printing we can examine the sheet of paper any number of times, provided we take care to do so in a subdued light. By examining it at short intervals (or long intervals, if the day is dull and the progress of darkening slow) we shall be sure to catch it at the point when it is enough printed and not too much. A print which is too much printed is too dark, and is irretrievable; nothing, too, can be done with a print which is too light. It must be right—not too dark and not too light.

Depth of Printing. As it is to undergo toning, during which it will lighten somewhat, it must be printed a fraction darker than we desire it to appear when finished. How much darker it must be printed can only be learnt by experience, but the beginner will soon have discovered, and thereafter need make no mistakes.

When the print is dark enough—that is, very slightly darker than would be desirable when finished—it may be removed from the frame (again working at the back of the room), and we shall now see that it is a reddish or purple hue all over, something like the curious colour made by an indelible or "copying-ink" pencil. The chemical changes to which it must be subjected will alter that hue to a more pleasing one. Their more important object, however, is to render the print permanent—that is, immune from spoiling by light. For obviously the print as it stands now is capable of still further darkening; and if we let it see much light, it will gradually become so black that the picture upon it will vanish altogether.

Toning and Fixing the Print. We have to do to the print what we did to the strip of film negatives after development—we have to fix it. Incidentally, while fixing it, we may change its colour to one which is more pleasing than its present one. For this purpose we must use the combined toning and fixing solution. *Toning* means altering the colour of a print. The colour is called the "tone"—a brown tone, a purple tone, and so forth. *Fixing* means taking out of the print the chemicals which render it sensitive to light.

If the dish which we used for fixing the film negative has been scrupulously cleaned, it may be used for toning and fixing the prints. Better still is to obtain another dish, also a deep porcelain one, and to keep it reserved for toning and fixing, while the fixing-dish for negatives is similarly reserved for its own special purpose. Half fill this dish with the toning and fixing solution. Should there be any sediment in the latter, no notice of it need be taken. Another dish or bowl of cold clean water, and a towel, should be handy.

The print is taken, holding it by the edge of one corner, and slid into the dish of toning and fixing solution, face upwards. It must be slid smartly and steadily, without any hesitation and without any splash, so that it is submerged as nearly as possible instantaneously. If it does not go under the surface of the solution completely, the dish should be rocked, so that a small wave of solution flows over the face of the print. It is important that the print should be covered as evenly and quickly as practicable, otherwise it will display irregular markings, for the solution gets to work upon it at once. The print's glossy surface is really a coating of gelatine, and this gelatine (like the gelatine on the film) absorbs the solution, which acts upon it in various ways. The only visible action is the toning—the changing of the print's colour. Should this toning be patchy, the effect will be very unpleasant; in fact, the picture will be spoilt.

Avoidance of Uneven Toning. The dish is rocked gently in order that the print may be kept submerged. Soon after its immersion the wetting may cause the print to curl up at its edges, these latter consequently rising out of the solution. Should this occur, the print, held by its extreme margin, may be lifted out of the dish bodily, nd slid in again face downwards, so that its back may be thoroughly wetted and any clinging air-bells dislodged. Do not leave the print in the solution face downwards; it should only be plunged in face downwards for a moment, then withdrawn and put back face upwards. After this, it ought to lie flat; but to keep it evenly submerged by the solution we may continue to rock the dish.

When the beginner becomes more at home with his materials, he will learn to tone and fix two or three prints simultaneously, one on top of the other, in the same dish. At first he should certainly only tone one at a time. In toning more than one at a time, it is very likely that they will stick together, and toning will be uneven.

Should parts of the print show a tendency to rise above the solution or float on it, these may be very gently pushed under by a finger-tip, if the finger is

absolutely clean and if the pressure exercised is cautious. Better still is to use one of those little instruments called a print-paddle, obtainable at the same shop as the Solio ; or the print may be pushed down with the glass stirring-rod if the latter is subsequently cleaned. Touch the surface of the print as little as possible, and never proceed to further printing, during which it will be necessary to handle dry sheets of Solio, without first washing and drying the hands if these have been soiled with the combined toning and fixing solution.

Almost immediately after being placed in the solution the print will probably alter from its pinkish or purplish colour to a disagreeable mustard-yellow. This presently gives place to a warm reddish-brown ; the reddishness gradually leaves the brown, and a pleasant pure brown remains. Should the print be left longer in the combined toning and fixing solution, it will arrive at a kind of pale purple colour, but in general it will be found that the toning is best stopped when the pure brown stage is reached. The print, however, ought not to be taken out of the solution while any redness remains. By lifting up the print and looking through it at the light, we can sometimes judge better whether the brown is through and through or not, rather than by looking at its face. All these operations can be carried out in a good light, but not quite at the window of the room. But once the print is into the toning and fixing solution, it has ceased to be liable to rapid darkening from exposure to light, and we need take no great trouble to shield it, though we should be unwise to let the dish stand in a flood of sunbeams.

Washing the Print. When the print has reached a stage of brown which pleases us—it is purely a matter of personal taste ; only the print should certainly not be taken out of the solution in less than five minutes, and should preferably remain in it for ten—we can lift it out of the dish, allow it to drip into the dish for a moment, and then plunge it into the vessel of clean water which we placed ready at the beginning of our experiment.

No further change will now take place in the print, as far as its appearance is concerned, but it must be washed —as the film had to be washed—in order to get the chemicals of the toning and fixing solution thoroughly soaked out of its gelatine. If this were not done, the picture would fade or stain when dry. The print may be washed by being given a number of changes of clean cold water. If the cold tap is allowed to run into a bath until the latter is 18 in. or 2 ft. deep in water, and the print, pinned by one corner to an old cork, is allowed to float therein, it will wash itself ideally. It must soak thus for an hour or an hour and a half ; by that time all the remains of the toning and fixing solution will have been washed out of the paper into the bath water, and sunk to the bottom. Floating clips may also be used for suspending prints in the bath.

Other prints may be made similarly, and toned one after the other in the same dish of combined toning and fixing solution, then put to float, attached to corks, beside their fellows in the same bath. After a good deal of use, the toning and fixing solution will grow muddy, and slow in its action. It should then be thrown away and a fresh bottle bought. But when only used for a few prints, the combined toning and fixing solution need not be thrown away ; it can be poured back into the bottle and kept for future use. Always wash out the dish very carefully after it has contained toning and fixing solution. It should preferably be kept solely for toning and fixing, but if used for any other photographic process this must be limited to fixing only. When the dish has been washed, stand it on its edge to dry, back outwards, so that the dust does not lodge inside it.

At the end of an hour or an hour and a half, the now washed print may be taken out of the bath, unpinned from its cork, and pinned by its edge to a clothes-line to dry, or pinned to a shelf, where it hangs so that the air can reach both sides of it. It should not be dried between blotting-paper.

Gaslight Printing. Velox paper, which is the alternative printing process to be described here, is very much more sensitive than Solio, and can consequently be printed by artificial light. Printing can therefore be done at night. The results, too, differ in appearance from those on Solio. Velox prints are of a pure black hue, while Solio prints are brown. Should our negative happen to be a flat one, Velox will further have the merit of giving us a somewhat brighter type of print than Solio. Various brands of Velox paper are to be had, in sixpenny and shilling packets, but for our first experiment we shall choose the kind called "Art" Velox. This gives prints of a pleasing semi-matte surface

For Velox printing we require a bottle of Velox developer and a tin of the same acid fixer as we used for fixing our strip of film. We must also obtain a couple of dishes, preferably of the same porcelain make as we chose for fixing and toning. One of these dishes should be the correct size for the print—that is, if our photographs are quarter-plate size, buy a quarter-plate dish, and so on. The other dish may conveniently be larger, or we may use the dish which was employed for fixing the film. The smaller of the two dishes is required for developing the Velox print—for Velox resembles film in that the image upon it is invisible after exposure, and can only be made visible by development.

When printing the Solio we are able to judge the progress of printing by examining the print from time to time and observing the depth of the image. This is impossible in Velox printing. The exposure of the Velox print has to be guessed in much the same manner as we guessed the exposure of our original snapshots. This does not mean that making a Velox print is really any more difficult than making a Solio print. In many respects it is easier and pleasanter, as a trial will show.

To make a Velox print we require a printing-frame—the same one which we used when making the Solio print. The frame, however, is not put up at the window to see the light—it is exposed to gaslight or electric light or lamplight, and this must be done at night, not during the daytime. It is possible to make Velox prints by daylight, but the beginner is not recommended to try it.

The room in which we are going to make Velox prints should have the lamp at one end of it and our work-table at the other. If the work-table must be near the lamp, the former should be screened from direct rays. If no direct rays fall on the work-table there is hardly any risk of fogging the Velox paper when opening the packet. Place the printing-frame, with the negative in it, at one end of the table, together with the packet of Velox, which for a start had better be the " Vigorous " grade.

Farther along the table—sufficiently far off to be certain that no splashes could reach the frame or the Velox—place a measure-glass containing the Velox developer. This latter is generally diluted with an equal quantity of water. The directions

on the label of the bottle must be followed faithfully. Do not be induced to try any developer but that sold specially for this paper, as developers made for "bromide" papers (which somewhat resemble Velox) do not give such good results. Beside the measure-glass is the smaller of the two dishes—the one intended for developing. It must be scrupulously clean. No amount of care is too great to take to see that none of the fixer gets into the developing-dish.

Next to the developing-dish there must be placed a bowl containing clean cold water, and next to this bowl is the fixer dish, which is half filled with the solution of the salts found in the tin. Do not be economical of fixer. It must be made up fresh for each batch of Velox prints; and it and the developer ought to be as near as possible to a temperature of 65° F. A test with the thermometer is worth while if there is reason to suppose that either of these solutions is too cold. If this turns out to be the case, the solution should be warmed—enough, but not too much. A clean towel must be kept handy, for in Velox-printing cleanliness of the fingers is of perhaps even more importance than in the other photographic processes. Everything is ready now, and we can open the envelope of paper and take out a sheet. This must not be done in the direct rays from the lamp; and as soon as one sheet has been removed for use the remaining ones should be wrapped up, or placed in a light-tight drawer.

The beginner who has never handled Velox before may possibly find a little difficulty in detecting which is the sensitive side of the paper and which is the back, for of course, like Solio, it is coated on one side only, and the coated side must be placed against the negative in the printing-frame. Art Velox is readily distinguishable even in a faint light, for its coated side is perceptibly shinier than the other. But if the photographer is in doubt he may recollect two tests for the coated side. The first indication is that the paper always has a slight tendency to curl with the coated side inwards. If no curl can be observed, the second test may be applied. Take up the Velox by its edge, and place the other edge between the teeth, bite upon it, and the coated side adheres momentarily to the teeth. Do not breathe on the paper while doing this. Having found the coated side, lay it face downwards on the negative in the printing-frame and place thereon the back, clamping the springs home.

The Position of the Light. The exposure is to be made by holding up the frame in front of the lamp. But as the exposure is a matter of a few seconds only, and as the light of the lamp does not carry far, it is obvious that the distance at which the frame is held from the lamp must be settled with precision, not left to chance.

In practice the frame should be held as near the lamp as will ensure the negative being evenly illuminated all over. Should we push the printing-frame close up to the lamp, the negative will be illuminated more brightly at its middle than at its edges, and the resulting print will have a spot of fully exposed detail in the centre and a falling off of detail all around. It is a rough rule, but a sound one, that the distance of the printing-frame from the lamp should be approximately equal to the diagonal of the negative. A 5 in. by 4 in. negative, for instance, should be exposed at a distance of, say, 6½ in. from the lamp.

Six or seven inches is a safe, useful distance to choose for all negatives of the usual small sizes. Before beginning to make Velox prints, it is well to measure off 6½ in. from the lamp; and a good plan is to tie a piece of string with a knot in it so arranged that, when the knot is held in the hand which grasps the printing-frame, the latter must be precisely 6½ in. from the light. In gaslight-printing this is easy, as the string may be attached to the gas-bracket. When printing by a standard electric lamp (which is the most convenient) the string may be tied to the standard. If a hanging electric bulb is used, the 6½ in. from its bottom should be measured and memorised—thereafter being judged by eye. The frame has, at all events, to be held at (we shall suppose) 6½ in. from the lamp, so that the light from the latter streams through the negative and on to the face of the Velox paper which is lying in contact with it behind. This is "exposure," and of course the question at once arises: How long should the exposure be?

Duration of Exposure. And this is precisely what it is impossible to answer off-hand. It all depends on the strength of the lamp and the density (that is, the darkness) of the negative. It is plain that if the negative is very dark the light will have more difficulty in getting through it than if it is less dark; and it is plain that more light will get through the negative from a powerful lamp than from a poor one.

The consequence is that the first exposure must of necessity be a guessed one. Subsequent ones, based on a knowledge from the first, need not be in the nature of guesses; and indeed the first itself will as likely as not turn out to be correct. In the leaflet of directions which accompanied our envelope of Velox some experimental exposures are suggested; and one of these, if tried, will probably produce a perfect print. With a bright, sixteen-candle-power electric bulb we may for a start guess that fifty seconds' exposure will give us a good print. This, be it noted, is on the presumption that we are using the "Vigorous" grade of Velox and placing the frame at 6½ in. from the lamp.

Taking up the printing-frame from the table, on which it has been lying face downwards so that no light should reach it before it ought, we move it quickly forward to a point 6½ in. from the lamp, and at once look at our watch and note the position of our seconds-hand. Accurate measuring of the time is essential, and a watch with a seconds-hand should always be used. If one is unobtainable, the photographer may count seconds for himself; but in that case he will do well to note that a second is of longer duration than he has perhaps supposed.

A simple and practical dodge for measuring seconds, which finds favour with many of the photographers of the old school, and may wisely be adopted, is to count audibly not "one," "two," "three," etc., but "one-hundred-and-one," "one-hundred-and-two," "one-hundred-and-three," and so forth. Seconds counted in this way are generally exceedingly accurate, while seconds counted separately, with a pause between each number, are inaccurate in duration, except when spoken by highly experienced workers. It is the pause which makes the measurement wrong. Velox paper has such latitude, however, and is so easy to use, that the minute errors which any beginner makes in the matter of exposure will probably not be discernible, even on his earliest attempts.

During the fifty seconds the frame should be very slightly moved up and down and from side to side (a mere couple of inches each way) to ensure that the lamplight is reaching it evenly all over. The moment the fiftieth second is up, we withdraw

the frame smartly and take it back to the table, where we lay it face downwards again. Opening the back of the frame, we lift out the sheet of Velox. Its front betrays no trace of a picture. The image thereon is latent—as was the image on our strip of film before we developed. Take up the Velox with care. It should be gripped by the extreme edge, and on no account should a finger-tip touch its face, or ugly markings will inevitably ensue.

Development. Lay the Velox face upwards in dish No. 1—the developing dish—and, taking the measure-glass of developer in the right hand, pour the developer, in one swift, smooth wave, on to the sheet of paper. The latter must be instantly submerged all over; and the dish is promptly rocked, so as to cause the developer to flow to and fro on its face. If the piece of Velox has been correctly exposed, the picture will appear at once, very quickly gaining in depth, until in about fifteen or twenty seconds it is as dark as we want it to be. No amount of further developing will cause it to go any darker. If it is too pale, the exposure has been insufficient, and we must make another trial, giving a longer exposure. If the print is very pale indeed, the exposure may have to be doubled or even trebled; if it is only not quite dark enough to be satisfactory, an exposure half as long again should suffice. On the other hand, if the print flashes up in the developer, and with great rapidity becomes too dark to be pleasing, the exposure has been too prolonged, and the next exposure must be shortened by judgment.

Fixing the Print. In some fifteen seconds or so, then, the Velox print may be removed from the developer. This should be done by gripping it, as before, by its extreme edge or by one corner. It is lifted out of the developing-dish and immediately dipped in the bowl of water which stands beside it. One swift dip in the bowl of water suffices to remove from its surface the clinging developer, and it is without an instant's delay slid into the fixer.

It is of the utmost importance that the print, while in the fixer, should be thoroughly submerged. If it shows signs of being inclined to float on the top of the fixer liquid, the latter should be quietly rocked until the print sinks. If it refuses to sink, it should be pushed under the surface, gently but firmly, with a glass rod or toothbrush-handle, or, better still, with a print-paddle. Should any part of the print lie above the surface of the fixer for a minute or two, and thus be exposed to the air, that part will subsequently show stains, generally of a disagreeable, rusty colour.

Washing. The print should remain in the fixer for not less than fifteen minutes. Thereafter the fixer is washed out of it in the manner described for films and for Solio—by floating in the full bath, pinned to a cork. Or the print may be washed by being transferred from one dish of water to another, a dozen times or so, the water in each dish being changed at each transference. When thoroughly washed, the Velox print is dried by being hung in the air like the Solio print. Meanwhile all dishes are scrupulously cleansed as before.

Both Solio and Velox prints are apt to show a disposition to curl a little when dry. The curl may be taken out of them by placing them under pressure, but a better method is to take a ruler, or some other flat-edged object, and pass the prints under it in such a manner as to impart to them a reverse curl, to counteract the original one. The print, that is to say, is laid face downwards on a piece of clean cardboard or other smooth surface, and the edge of the ruler pressed lightly above. Draw the print under the ruler-edge so that the former is caused to drag along the cardboard and be turned upwards as it emerges from this pressure. Two or three pulls under the ruler will straighten it out absolutely flat.

The same method of flattening applies to post-cards, which also curve inwards. Here it may be remarked that the treatment of postcards is the same throughout as that of paper prints.

Trimming the Print. The finished print is surrounded by a margin of white or black, due to the overlapping of the rebate-mark of the negative or the edge of the printing-frame. This margin is of no consequence if the print is to be placed in a "slip-in" album, whose openings in the leaves are of such a size that they automatically have the effect of trimming or framing the picture. Ordinarily, however, we shall want to cut off the margins, to make a neat job of our picture.

This cutting off of the margins, called trimming, may be done with care by using the point of a sharp pocket-knife guided by a straight-edged ruler, the print meanwhile lying face upwards on a backing of cardboard or a pile made of sheets of old newspaper, To cut the corners true by this means is, however. none too easy to the beginner, and he will be wiser to invest in a little appliance named a print-trimming board, which is squared true, and furnished with a guillotine blade and handle. The print-trimming board costs a trifle, and trimming pictures by its aid is rapid and pleasant.

Mounting. Various methods of mounting the print are in vogue, and are too detailed to be described here. The simplest is the *dry mounting* system, with the apparatus for which are full instructions. *Mounting-tape*, which is a strip of paper with adhesive on both sides of it, is also useful, and should be brought to the notice of the amateur who does not wish to go to the expense of the dry-mounting materials. Mounting-tape, correctly used, entirely supersedes the old-fashioned, messy method of mounting with paste. Paste-mounting, in fact, except in the hands of the most dexterous workers, is so unsatisfactory that we shall not deal with it. The amateur who wishes to escape the labour of mounting altogether will prefer, at any rate, to purchase mounts or albums ready-made with prepared openings of the aforementioned "slip-in" variety. These have the further advantage that the prints in the mounts or albums need not remain there permanently; they may be changed as often as wished.

The foregoing pages have dealt with photography as it is practised by the great majority of amateurs—those who photograph because they want to make pictures of the things they see, and to make these pictures with the minimum of effort and trouble. But there are some on whom the pastime grows until the means becomes more fascinating than the end—the taking and the making are frequently more important to them than the resulting photograph. They become what are generally known as "serious" photographers. They do not mind carrying heavy and fragile glass plates instead of the light and unbreakable Kodak film. They do not mind having to spend hours in dark-rooms working at different processes.

It must not be thought from this that the Kodak is not used by advanced workers. Many of the finest pictures shown in the exhibitions are enlarged from film negatives taken in Kodaks.

The Bare Land and its Preparation. Laying out the Useful Garden. The Kitchen Garden. Hedges, Walks, Lawns, and Beds, Rock, Water, and Wall Gardens.

THE GARDEN BEAUTIFUL

BETWEEN the wide expanse of pasture land which it is proposed to transform into a market garden, or beautify as an adjunct to a mansion, and the tiny plot of the suburban house, covered with builders' debris and overrun with weeds, there does not, at first sight, appear to be much connection. Yet, vast as the science of horticulture is, the same principles can be applied, with certain modifications, to the garden of the millionaire and to the tiny pot-plant struggling for life on the window-sill of a city slum.

It may appear superfluous to remark that anybody who desires to attain a knowledge of gardening must begin at the beginning, but there is a reason for saying so. Buying plants from a nursery in the springtime and putting them in the ground is not gardening, any more than paying a man to do all the hard work is, and, therefore, to acquire proficiency in horticulture, a novice must go right "back to the land" in its original condition.

The First Step in Gardening. The first step to be taken is to find out the nature of the soil one has to deal with. The chief constituents of all earth are one or more of the following substances in various proportions—clay, sand, gravel, lime, and decayed vegetable matter. Take a spade and turn over a few spits (a spit is a layer of earth the depth of a spade's blade) of the soil on the land or garden it is proposed to cultivate. Dig down to some little depth, as the character of the soil often varies somewhat two or three feet below the surface.

Now examine a spadeful of the earth. If it be thick and "stodgy" with clay, it is what is called a heavy soil, and will need a good deal of improving. If it contains a fair amount of sand mixed with clay, so that it is not sticky and sodden, it is a natural loam, the most precious of all soils to the gardener. Should there be so much sand, however, as to make it dusty and crumbly, it is known as a light soil, and wants careful handling. Where a large amount of chalk enters into the composition of the ground, as in many parts of Kent, and on the Surrey hills, the soil is called a calcareous one, and in its natural state is specially suited for the culture of many sorts of vegetables. The richest of all soils, though not the most useful for general purposes, is peat. This may be distinguished by its very dark colour, and the presence of decayed vegetable matter. It is met with most frequently in damp situations, and really represents the first stage in the transformation of vegetable matter into carbonaceous matter.

Draining and Levelling. When once the nature of the soil is known, it must be drained and levelled if the area is of considerable extent. Town and suburban gardens are, of course, already drained, and are generally of such limited area that they require no levelling. A simple and effectual way of draining is to dig a series of narrow trenches, six yards apart, from the highest points of the ground to the lowest, laying at the bottom of these trenches, which should be 3 ft. or 4 ft. deep, so as not to interfere with the roots of plants, a row of common earthenware pipes 3 in. in diameter. These must communicate with a larger, or main, drain pipe, which empties itself into a pond or stream, if one exists, or, if not, forms the nucleus of a pool, which, by this easy and natural process, becomes an admirable site for the water garden.

It is not necessary to give much attention to levelling a garden. The need for it is non-existent in the small suburban garden, and, as far as the market garden is concerned, levelling is a waste of money and time, except when sites for rows of glasshouses have to be prepared. For this purpose, however, and also for the formal part of the garden near the mansion, and in the preparation of tennis lawns, bowling greens, and other flat ground, some levelling must be done.

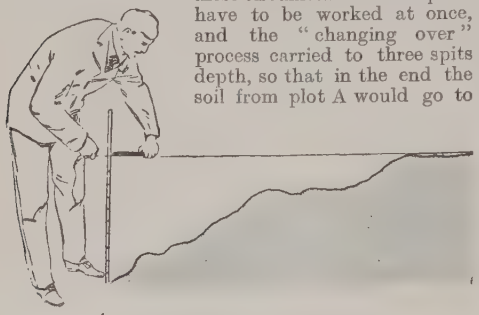
How to Level the Garden. This can be accomplished by very simple means. A peg, a length of cord, a stick marked with feet and inches, and a spirit-level are all the implements that are required. At what is judged to be the highest point of the ground to be levelled, a peg, with the cord attached to it, must be firmly driven in. Thence the cord must be extended over the whole area until the lowest point is found. This is done by sliding the loose end of the cord up and down the measured stick at various points [1] until, by means of the spirit-level, the difference between the highest and lowest points of the ground is discovered. For the sake of illustration, suppose this to be 4 ft. Therefore it is necessary, in order to establish a common level, to throw 2 ft. of the soil from the highest part of the land on to the lowest part.

In practice more than this must be done, and the low parts to be filled should be built up to at least 6 in. higher than the spots from which the earth is taken, to allow for subsidence, and also for compression when the roller is applied.

Digging and Trenching. The question of removal of soil brings us to the all-important subjects of digging and trenching. Digging is, of course, the simple act of turning over earth with a spade, but trenching is a term which the novice will need to have explained to him. Perhaps the definition given by J. C. Loudon, one of the greatest authorities upon gardening, is the simplest: "Trenching is a mode of pulverising and mixing the soil, or of pulverising and changing its surface, to a greater depth than can be done by the spade alone." This changing about of the soil in a garden is necessary for the purposes of aerating and sweetening it, as earth which is left too long undisturbed is apt to get foul and stagnant.

The simplest form of trenching is what is known as two-spit, or bastard trenching. Let us call two parts of the garden A and B. First the top spit and then the second spit of A are removed to a neutral spot, and the same is done with B, keeping the respective spits separate. Then the top spit of B is placed where the second

spit of A was, and the second spit of B put on top of it, while the top spit of A is placed at the bottom of plot B, and covered with the bottom spit A. In other words, the soil in the two plots A and B is taken up, turned upside-down, and made to change places [2]. For many gardens, especially suburban ones, where, as a rule, the soil is shallow and rests on a solid bed of clay, this form of trenching is sufficient, but where the soil is deep the operation of trenching is more complicated. In these circumstances three plots have to be worked at once, and the "changing over" process carried to three spits depth, so that in the end the soil from plot A would go to



1. LEVELLING THE GROUND

C, from B to A and from C to B, but inverted, so that what was once the top spit of A would be the bottom spit of C, and so on.

The Nature of the Soil. During the process of trenching, which may well be carried out while levelling is going on, much improvement can be effected upon bad soils. They may, first of all, be rendered more workable by causing the stones and pieces of brick to be picked out. Such refuse is generally to be found in a garden attached to a new house, where the builders' men have buried it in order to avoid the trouble of carting it away. These pieces of bricks and stone should by no means be discarded, but placed at the very bottom of the trench when levelling, in order to assist drainage.

The drawback to a heavy clay soil is that, being impermeable, it will not allow the rain to pass away, and, as a consequence, gets very sour. It is obvious, therefore, that anything which will tend to lighten or break up this heavy clay will be of advantage. This being the case, the autumn is the best time to commence the formation of a garden. The ground should be trenched as already described, and left as open as possible. Then, when the winter frosts come, the water which the clay contains will freeze, expand, and to some extent force the particles apart to admit air, and thus the soil will become somewhat more open and workable by the time the springtime arrives.

Manure. In these early stages the only manure, if any, which should be applied is a layer of horse manure, with plenty of straw. This should be placed at the bottom of the trenches—that is, after the earth has been dug out, and before it is replaced. Though this does little to lighten the soil, it increases its fertility to some extent.

Before beginning digging operations it will probably be found necessary to clear the ground of weeds and long grass. None of this refuse should be thrown away or wasted, but carefully stored and thoroughly burned, and the ashes dug into the ground. This process should be repeated at intervals with anything in the shape of rubbish that is capable of being burned. It is well, however, to change the situation of the bonfire each time, even as the heat and the action of the flames on the earth are beneficial to a heavy soil.

Road sweepings, with the grit they contain, are of great value under certain circumstances. This remark applies chiefly, however, to the sweepings of country roads. Recent developments of motor traffic, and constant droppings of oil refuse, have rendered the road sweepings of town streets of comparatively very little garden value.

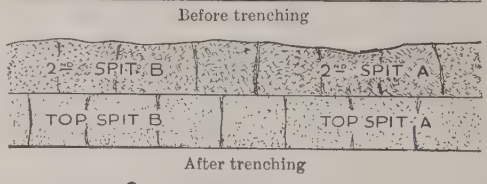
It is not sufficient merely to deposit the ashes, grit, and other lightening materials upon the ground. They must be dug over well and constantly until they and the soil are thoroughly well mixed up, as otherwise no beneficial results will be obtained.

Improving the Soil. By dint of patient and constant work it is thus quite possible to turn what was once regarded as a hopeless mass of clay into a fairly open, if somewhat heavy soil, while the presence of clay underneath at a depth of from 2 ft. to 3 ft., according to the distance trenched, is an advantage rather than otherwise, as it retains the moisture during the hot summer months, and so enables the roots of the plants to keep cool and prevents them being parched.

Improving a soil which is too light or sandy is not such an easy matter as improving a heavy one. The process may, of course, be reversed, and some clay introduced to thicken the ground, but the mixture rarely proves to be a satisfactory one. To make the best of a very light soil, it is necessary to trench it very deeply and openly before planting in the spring. This has two beneficial results. As the soil is thus rendered loose, the roots of plants can easily penetrate to a great depth in order to get at the moisture which is so necessary for their welfare; while, on the other hand, this treatment allows the rays of the sun to penetrate the ground freely, and so draw the moisture towards the surface.

When once the operation of trenching has been carried out, it is better temporarily to discard the spade for the garden fork in turning over the soil. Lumps of clay can be broken up more finely with a fork than with a spade, in addition to which the operation is not so fatiguing to the worker.

Foreign Elements in the Soil. In the course of these digging and forking operations, many large stones are sure to be met with. These should all be removed and set aside, as they have their use. They may be used to form the basis of a rock



2. TWO-SPIT TRENCHING

garden, which is described in more detail later; or, if too small or misshapen for this purpose, can be added to the contents of the bottom of the trench, as mentioned above.

Occasionally it happens in the course of digging that what appears to be a reddish-brown "vein" is struck. If this occurs, immediate action should be taken, as it indicates the presence of iron in the soil. Now, iron in a soil has a great tendency to render it

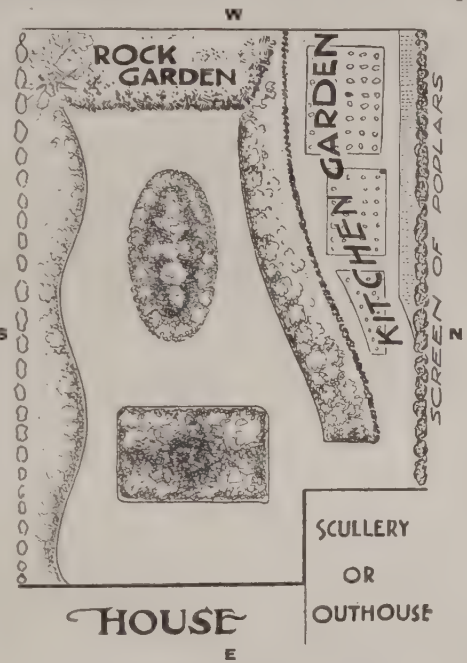
unproductive, so that prompt treatment is necessary, and a dressing of lime should be dug into the affected part. The iron is invariably in the soil in the form of an impure sulphate, and the lime combines with the sulphuric acid in the iron sulphate, and forms sulphate of calcium, thus sweetening the soil and eliminating the dangerous compounds.

Magnesia, manganese, sulphur, phosphorus, soda, and chlorine are all found in varying proportions in soils of different natures. Where they do not occur naturally, and are required for the welfare of one plant or another, they must be supplied by artificial means, and this is the fundamental principle of chemical manuring, of which more will be said.

LAYING OUT THE GARDEN

Before beginning to lay out a garden it is obviously necessary to decide what sort of a garden is required. There is the garden for pleasure only, which is a flower garden pure and simple; the garden for profit—as distinguished from a market garden—the owner of which has merely an eye to the abolition of greengrocers' and fruiterers' bills; and the general purpose garden, which is a combination of the two, and is the garden usually met with, as well as the most useful.

The majority of very small town and suburban gardens are unsuited for the culture of fruit and vegetables, with the exception of a few kinds, and must, perforce, be gardens for pleasure only; but there is no spot, however barren and smoke-ridden it may be, which will not lend itself to gardening of some sort. In cities and towns a good guide as to what may be grown with reasonable chance of success will be found in a visit to the local park, and a study made of what flourishes therein. In very smoky spots the secret of success is to water the foliage of plants freely, in order to wash away the particles of soot which accumulate.



3. PLAN OF A SMALL GARDEN
Showing kitchen garden and screen of poplars

The Aspect of the Garden. The very first thing that should be done with a piece of ground which has been levelled for gardening purposes is to determine its position with regard to the points of the compass. An ideal garden of moderate dimensions is oblong in shape, with the long sides facing north and south, while the house is at, and facing, the east end of the plot. In such a position the building protects the contents of the garden to a considerable extent from the cutting east winds, while there is a good expanse of south wall for the culture of fruit. Many a fruit-tree or half-hardy plant, which would die of exposure in any other situation, will thrive on a south wall, or in the border at its foot. Moreover, a south wall gets the benefit of the sun for the whole of the day, in summer and winter, and is its own protection from north winds. The terms south, north, and so on, when applied to walls in gardens, do not mean that they are situated in that particular part of the ground, but that they have a southern or northern aspect, as the case may be.

The novice visiting a garden of any pretensions for the first time frequently wonders why it is situated at one side of the house instead of at the back. It is just this question of exposure to sun and winds from different quarters that has provided the reason, and the same rule holds as good for the 12-ft. patch as for the nobleman's broad acres. The worst position of all for a garden is one in which the house faces west or south-west, as the garden has practically no shelter from the icy blasts from east and north. In laying out such a garden, therefore, plants of the most hardy nature must be chosen.

One of the first questions which will enter the would-be gardener's mind, as he stands at a back window and contemplates the waste which he is to make fertile, is: "How much of this ought I to devote to fruit and vegetables, and how much to flowers?"

A great deal depends upon local conditions. If the district is one well furnished with markets in which fruit and vegetables are procurable at reasonable rates, it is better to devote the bulk of the space to floriculture, reserving a little for the choicer products of the kitchen garden. If, on the other hand, vegetable produce is dear, and, as is often the case in country districts, consists chiefly of inferior local varieties, it is wise to make the kitchen garden at least half of the total area. This remark applies to gardens from which it is hoped to derive both pleasure and profit.

The Kitchen Garden. Having decided what proportion of the ground to be laid out is to be devoted to kitchen garden purposes, the next step is to mark it off and divide it from the flower garden. Useful though they are, vegetables grown, as they should be, in symmetrical rows, like regiments of soldiers, are not a particularly alluring prospect in a garden landscape, and it is usual to separate this portion of the garden from the pleasaunce by a hedge of some description—a subject to be dealt with later.

In the smaller gardens it is usual to find the kitchen garden consisting of a corner lopped off indiscriminately from whatever part of the ground happens to be situated at the farthest point from the house, irrespective of situation or aspect. This is a mistake. The question of aspect is just as important for the successful culture of fruit and vegetables as of flowers, and, speaking, as a rule, in the case of the orthodox oblong garden, the vegetable portion will best repay attention if it is formed of a strip running parallel with the flower garden for practically the whole length of the ground. It may

be stopped within a few yards of the house or eased off into nothingness, so as to give the broadest expanse of bed or lawn near the house [3].

If a very large garden is in course of preparation the kitchen garden is, of course, a thing apart, and is kept away from the flower garden altogether. In these cases a position on a southern or western slope is usually assigned to it if such be available, but the laying out of places of such dimensions is not usually entrusted to an ordinary head gardener. A specialist, known as a landscape gardener, is invariably called into requisition, and the resident gardener and staff work upon the lines which he lays down.

Improving the Aspect. Though the question of aspect is one of the utmost importance, a good deal may be done to improve a bad situation. Where a garden is swept by east or north winds, a screen of trees, such as poplars, will assist matters materially. Certainly, unless large-sized trees are obtained in the first place—and this is a somewhat costly business—some time elapses before the benefit of their presence is felt; but when once established, the advantage they offer is permanent. It should always be borne in mind, however, that on no account should a screen of trees be placed close to a house. In the first place, if the house has any pretensions at all to architectural beauty, the presence of trees, or tall-growing shrubs, in its immediate vicinity will sadly mar its dignity, while, in addition, big trees close to the house should be strongly discountenanced from a hygienic point of view. A house hemmed in by big trees is always damp, and they offer obstruction to light and air. In addition, such a screen of trees naturally has a deleterious effect upon the soil, as it impoverishes it, sucks it dry of moisture, and, with a few exceptions, renders plant life impossible within a considerable radius of its branches.

The Garden Walks. The question of walks and paths and where to put them is one of paramount importance in laying out a garden. At least 90 per cent. of gardens of all kinds in this country are wretchedly undersized little places, and yet the tendency is to reduce the available space in them by the introduction of needless walks, leading nowhere in particular, and serving no good purpose. It is a good plan when beginning operations to draw a rough sketch of the ground, marking upon it the different spots at which the kitchen, rock, water, and other gardens, if any, are to find a place.

Then, starting from the house, decide the simplest and quickest routes by which the different parts can be reached. Here a certain amount of discrimination is necessary. There is no need for the paths to radiate with geometrical accuracy like the spokes of a wheel from the back of the house. A graceful curve, for which perhaps the presence of a tree or a rise in the ground will give a pretext, is not only desirable, but to a small garden will give the impression of increased size. At the same time it is absurd to have a lot of serpentine walks wriggling about the place just for the purpose of conveying the idea of great length, while bisecting and trisecting lawns with walks until they look like a problem in geometry is an equally foolish proceeding.

Grass Walks. Unless a garden is of unusual dimensions, three or four main gravel walks, at the most, will be all that will be required, and, for the rest, let the turf come right up to the beds or borders, so that what would under ordinary circumstances be gravel paths are simply grass walks. There are many advantages to this system. The rich green turf forms a far more beautiful setting for a bed of flowers than a gravel path does. It is easier to keep turf in good order than it is to be continually weeding gravel, and although it is urged as a drawback that turf walks are unfit for walking upon after rain has fallen, this is only the case where they have been improperly drained. Moreover, should it be desired at any time to change the character of a garden, this can be far more easily done in a turfed place than in one where gravel walks, running at different angles, have to be taken up and altered.

Making Beds and Borders. Mention has been made of the words "bed" and "border." A bed is a piece of ground in the garden, prepared for cultivation, but which has no direct protection from a wall, fence, or hedge. A border may be best described as the long strip of earth close up against a wall, fence, or other means of protection. For instance, the strips running round the three walls of the ordinary suburban back garden would be called borders, while the circular plot in the centre, if there is one, would be a bed.

In making a bed, after having decided upon its shape, it is best either to peg the shape out upon the ground with sticks and string before commencing operations, or else plan it out in whitewash, like marking a tennis crease. This will prevent the possibility of a mistake. The simple precaution in making a border is to stretch a string taut between two pegs from end to end to ensure a correct edge, as nothing looks worse than an irregularly shaped border, unless the shape of the wall or garden demands it. If the whole garden is a new one and the ground has been treated on the lines laid above, no other preparation is necessary, but where it is proposed to cut a new bed or border out of an existing garden, the ground must be well worked as advised before planting.

The Front Garden. What to do with the front garden is a great source of perplexity to town gardeners, for it is only near the busy centres that the front garden proper finds a place. Most of them solve the problem by planting laurels and privets, a method which, if it has the merit of simplicity, is certainly not the best possible solution.

Though many flowers might be grown in such situations, particulars of which will be given in due course, there is always the danger of their being stolen; but a much wider range of trees and shrubs is available for town use, which have the advantage, moreover, of not being so greedy or exhausting to the soil as the laurel and privet. Of these, some are evergreen, and include rhododendrons, yuccas, azaleas, aucubas, hollies, and euonymus; while those that are deciduous (lose their leaves in winter) comprise weigelia, ailantus, cotoneaster, philadelphus, mountain ash, sumach, elder, ash, plane, elm, and others of our native forest trees. Collections of some of the different sorts of ivies, too, will be found very useful in helping to beautify the town and suburban front gardens.

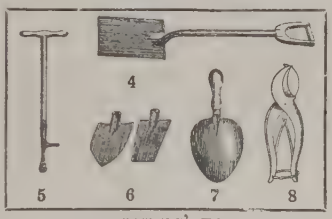
Simplicity should be the keynote of front gardening, and the idea of putting a monkey puzzle opposite the front door and surrounding it at a respectful distance with standard rose-trees is dying out, even as the rhododendron is beginning to oust the laurel from pride of place as a necessary adjunct to such arrangements.

The Rubbish Heap. No matter what the size of the garden may be, a rubbish heap is a necessary evil. It is best to situate it in the most unfavourable part of the garden, and hide it by a screen of privets, or a trellis of woodwork covered by Virginian

creeper. It will naturally be made up of cuttings, trimmings, and all sorts of garden refuse. This should be burned at intervals, and not allowed to accumulate for any length of time, as it breeds and harbours insects. In the summer-time it is a good plan to throw a few spadefuls of earth over the vegetation and allow it to decompose, as such decayed vegetable matter forms a good manure, and will be found of great assistance later in the year.

The Gardener's Tools. The most important garden tool is, of course, the spade [4], which is an implement perfectly distinct from the shovel, although the names are often interchanged, and one tool used for the purpose of the other. The spade is used for digging, and the bottom of the spade should be of steel, and the upper part of iron, thoroughly welded together. Young gardeners often suffer pain, when digging, from the pressure of the foot on the tread, or shoulder, of the spade. This can be obviated by using a little contrivance called a "digging shoe," a sort of anklet of leather which buckles over the middle of the foot, so that there is a good layer of leather acting as a protector where the foot presses on the spade. Spades are made in four sizes—1, 2, 3, and 4, of which No. 3 is probably the most useful implement.

The Shovel, Fork, and Rake. The shovel [6] is used for shifting loose soil, clearing trenches, handling manure, and similar purposes. Its blade is broader than that of the spade, and it is usually pointed, so that it can be pushed into piles of loose earth more readily than the spade. A shovel with a long handle is the best, as this obviates the necessity for stooping.



GARDENERS' TOOLS

4. Treaded spade 5. Bulb planter
6. Shovels 7. Trowel 8. French secateur

The garden fork is a most useful though somewhat neglected implement. Much of the work of breaking up ground, which is at present done with the spade, could be done far less laboriously with the fork. A four-pronged fork is the most useful, though some are made with three and some with five prongs. The fork is particularly useful in stirring the surface soil between plants, to aerate it. Short-handled forks are handy implements for taking up small roots, transplanting, or weeding, being, for this purpose, generally handier than the trowel.

The rake is not so much used as formerly, except the wooden variety, which is used for removing dead leaves from lawns, and other similar purposes. There is a variety of rake, however, called the "daisy rake." This has short teeth, very close together. It is used to drag over lawns, to pull off the heads of daisies, dandelions, and other lawn weeds.

Lawn Mowers and Other Tools. Lawn mowers vary a good deal in detail, but most of the best makes are so equal in merit that there is little to choose between them. It is well to consider the area of the grass to be mown in selecting a lawn mower as far as size is concerned. A large lawn mower on a small lawn means expenditure of unnecessary labour, and the same remark applies to the opposite condition—a small mower on a large lawn. The chief thing to be observed is to keep the cutters properly sharpened, as an attempt to mow a lawn with blunt cutters is simply waste of time. The edges of grass which the mower cannot well reach must be cut by means of shears, which are made with both straight and curved handles. In a very large garden it is usual to employ a motor lawn mower.

The pruning knife has been almost superseded by the secateur [8]. This instrument is really a sort of miniature shears, and, in the hands of an inexperienced gardener, is certainly a much better implement than a pruning knife, as it makes a cleaner cut, and there is less danger of cutting away too much with it.

The trowel [7] is an indispensable little implement for transplanting cuttings and small plants. First of all, the hole to receive the plant should be made, and then the trowel should be used to scoop around the root of the plant, and lift it out bodily, when it can be carried on the trowel and placed in the hole prepared for it. A bulb-planter [5] is particularly useful for planting bulbs in lawns.

Other gardeners' tools include the watering-pot, wheelbarrow, saw, and hammer, the uses for which are obvious.

The Little Back Garden. The poor little square patch which is known to the town dweller as the back garden is the most handicapped piece of soil in the world. It is situated so that surrounding walls and sides of houses either cut off air, light, and sun from it altogether, or else admit the blinding glare of the sun's rays to scorch the ground up, while effectually screening any refreshing breezes. Further, the prevalence of smoke chokes up the pores in the stem and leaves of the plants, and prevents them from breathing, while the elaborate systems of drainage with which all towns and cities are replete act indirectly upon the gardens by drawing away the moisture from the subsoil. Without this moisture in hot weather the roots of plants can never be healthy, and success in cultivation becomes more difficult.

Laying Out the Small Garden. These little back gardens are usually square, and where any attempts at gardening are made they generally take the form of a narrow border running all the way round, while the remaining space is devoted to turf, with, perhaps, a circular bed in the centre.

The one point in favour of this plan is its simplicity, but it has the effect of making a garden look hard and formal. A more picturesque way of laying out a small garden is to make the border of an irregular width, curving it in and out as fancy directs, easily and gracefully, though never in such a complicated manner as to appear grotesque.

The centre of the garden can either be laid out simply as grass (the best method where there are children, as it gives them just a few yards to play in), or it may be broken up by arranging for the planting of one or two flowering shrubs, or by the introduction of a bed or beds, as may be desired. A very interesting and easily attained feature of a town garden is a small bed treated as a rock garden, particulars of which are given later.

Trees and Flowers in Town Gardens. Large trees are a mistake in a very small city garden. Although it seems a pity to advocate the cutting down of even one tree, there can be no doubt that their presence in a tiny back garden is a grave menace to the health of the inhabitants of the house, and also militates against success in growing plants, owing to the terrible drain it is upon the nourishing elements in the soil. The same remark applies, to a certain extent, to laurels and privets, which form the lazy man's garden.

The names and habits of many flowers and plants suitable for city culture will be found in later pages, but for general use it may be mentioned that the most useful climbers for hiding walls and fences that face the east or north are the Virginian creeper and Rægner's, or a variegated ivy. Variegated ivies like poor soil; it brings out the variegations better. For sunny situations, purple and white clematises, Veitch's ampelopsis [11], or vine, Canary creeper, Japanese hop, and yellow, winter-flowering jasmine are the best. Of shrubs, the best are the mock orange, aucuba, flowering currant, variegated euonymus, rhododendrons, and Syrian hibiscus.

These may be put in when the laying out of the garden is first begun. If put in in the autumn, a handful of straw laid round the bottom of the stem of the shrub will prevent the frost from getting at the roots.

Window-boxes. Every window, whatever its aspect, can have a box upon its sill in which flowers will grow [11]. Such boxes, with tiles or ornamental fronts, are to be bought, but there is an easy way of making them. Measure the window-sill, and make a box to fit it, about 9 in. deep. Get a piece of clay, and daub it, putty-wise, along all the joints and corners, so as to make it water-tight. To each bottom corner nail a strip or block of wood about an inch deep, so as to prevent the box from standing close on the window-sill. In the middle of the bottom of the box bore three or four small holes, about a couple of inches apart from each other, to allow superfluous moisture to drain away readily.

It is a good plan, in the case of an upstairs window-box, to slide a shallow tin, such as the lid of a biscuit-box, underneath the drain-holes of the window-box, to collect the superfluous moisture. Fill the box to about one-third its depth with bits of broken flower-pots, china, brick, stone, or any similar material, to form drainage, and then fill it up with earth which has been carefully picked over or sifted, to get rid of all big stones, and well mix with silver sand. The window-box need not be a thing of beauty in the summer-time only. When gardening operations begin in the autumn, some dwarf conifers should be put in to keep the boxes bright during the winter, and at the same time bulbs must be planted to keep them gay from March till June.

9. RHODODENDRON BLOOM

One of the most important points in connection with window-box gardening is that the plants should have sufficient water in the winter-time. It is just the season when plants fully exposed in the open air are being soaked by wet and snow, so that if the window-box is in a sheltered position it should be watered, if not as frequently as in the summer-time, at least twice a week.

Trees and Shrubs for the Town. It is impossible to expect a good garden if the trees and shrubs which it contains are either of the wrong sorts or are wrongly planted.

Of the trees most suitable for planting in town gardens, the following is the best selection: Sycamore, common almond, plane, poplar, common elder, horse chestnut, American cherry, ailantus glandulosus, and most of the hollies, which, although of slow growth, will more than repay the care bestowed upon them within a few years after planting. The same remark applies to the euonymuses, of which the variegated sorts are preferable.

A box-hedge is, of course, preferable to one of privet, but, like the holly, the box is of such slow growth that unless a permanent residence is anticipated it is doubtful whether it is wise to plant such a hedge. As an edging in a formal garden, however, there is nothing to equal clipped box.

An excellent, though much neglected, tree for a suburban garden, especially where there is anything in the shape of a lawn, is the black mulberry (*Morus nigra*). Not only does it thrive under the most unfavourable conditions, but yields a generous supply of delicious fruit in the autumn. It is for this reason that it must be grown in grass, as otherwise the fruit—which should not be gathered, but allowed to drop—will be injured when it falls to the ground. The presence of the turf prevents it from getting damaged.

The best evergreen shrub for town planting is undoubtedly the rhododendron [9]. Until lately it was thought to be not quite hardy, but by means of hybridisation many kinds, embracing all colours, are procurable. The old-fashioned ponticum rhododendron is now usually relegated to country-side coverts.

Trees and Shrubs for General Planting. Trees and shrubs which may be used for general purposes in gardens throughout the country embrace some thousands of species. Many of these will thrive only in the sheltered gardens of the South and West of England, and it is useless to attempt to grow them in other districts. They are divided into two classes, one known as deciduous, or summer-leafing, and the other as evergreen. The latter class keeps leaves all the year round, while, during the winter months, the deciduous kinds have nothing but bare stems to show. At the same time, the most brilliant displays of bloom are usually to be found on the summer-leafing shrubs and trees.

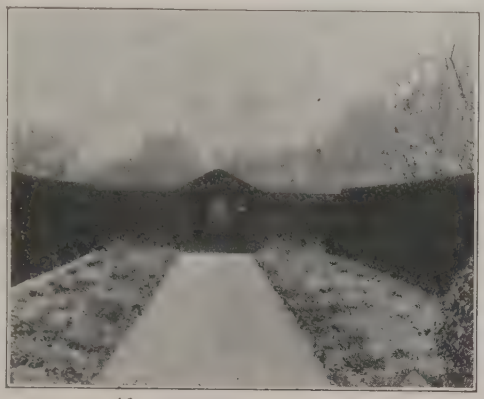
A list of the most useful evergreen trees and shrubs includes the following: Andromeda, arbutus, aucuba, berberis, cerasus, choisya ternata, cistus, cotoneaster, daphne, elæagnus, erica, escallonia, euonymus japonicus, garrya elliptica, hedera, ilex, kalmia, laurus nobilis, olæria haasti, quercus ilex, rhododendron, skimmia, ulex europæus, veronica, vinca major and vinca minor, and yucca gloriosa.

The following are among the best of the summer-leafing sorts: Acer, æsculus, ailantus glandulosus, alnus, amelanchier, amygdalus, aralia spinosa, azalea, berberis, betula, buddlea globosa, calycanthus floridus, carya, catalpa bignonioides, cerasus, corylus avellana, cotoneaster, cratægus, cytisus, daphne mezereum, deutzia, elæagnus augustiofolia, fagus, forsythia, fraxinus, genista, hamamelis, hibiscus, hydrangea, juglans regia, kerria japonica, laburnum, liquidambar, liriodendron tulipifera, magnolia, morus, persica vulgaris, philadelphus, platanus

orientalis, populus, prunus, pyrus, quercus, rhus, ribes, salisburia adiantifolia, salix, sambucus, spiræa, syringa, tamarix gallica, tilia, ulmus, viburnum, and weigelia.

How to Plant Trees. Upon the proper planting of trees at the outset their future welfare depends. It is not sufficient merely to dig a hole in the ground, cram the roots of the young tree or shrub into it, throw back the soil, and make the whole thing firm by stamping upon the base of the stem with an iron-shod boot-heel.

In preparing a hole for the reception of a tree or shrub, it is best to dig it wide and shallow, rather than narrow and deep. The roots should be examined carefully before planting, and any that are broken or injured cut away with the pruning-knife or secateur. The roots should be well spread out in the hole, and the soil gently but firmly pressed in.



10. CLIPPED YEW HEDGES

Should the weather be dry, the young plants should have a liberal dose of water as soon as they are put in the ground. Trees or shrubs that are planted on hillsides, or in other open situations, where they are likely to be exposed to the full force of the wind, should be supported by means of stakes driven firmly into the ground, to which they should be fastened, the stakes being left in for two seasons.

The Time for Planting. Trees and shrubs may be planted with safety at any time between the autumn and early spring—say, from October to March. The bulk of planting is usually done in the autumn, as at this time work is slacker in the majority of gardens than it is after the turn of the year. In town gardens, however, and others in which the soil is of a poor quality, advantage is often to be derived by deferring the planting till the spring. The reason for this is that the roots have the whole of the summer in which to get established before being called upon to undergo the rigours of a winter. A comparatively thin crop of bloom for the first season is the only penalty for this precaution.

Planting should never take place in wet weather, or when the ground is sodden with moisture, as shrubs and trees planted under these conditions are more likely to rot than thrive. It is also useless to attempt planting when the ground is frozen hard, for not only is digging then almost an impossibility, but the soil cannot be properly replaced, and frost will percolate to the roots through the crevices left, and kill the plants. When, of necessity, planting must be done in frosty weather, it is well to cover the surface of the ground round the bases of the stems with a layer of straw, litter, or other mulch, to afford protection from frost.

Transplanting Large Trees. To transplant a large tree, it is first necessary to expose its roots. This is best done by loosening the soil around the base of the tree, preferably with a fork. In judging the distance to which it is necessary to excavate in order to expose the roots of a tree, it should be remembered that, as a general rule, the spread of the roots beneath the surface of the ground is equal in diameter to the stretch of the branches above.

The soil should be carefully cleared away with shovels, care being taken not to injure the roots, which should be lifted up out of harm's way as exposed. When the soil underneath the tree has been well tunnelled, a shallow trolley should be run underneath, and the tree carefully levered on to it, being held in position by props consisting of young larch poles, and secured with ropes. It is well to lift the tree with as large a ball of soil attached as possible, as this not only prevents damage, but helps the tree more quickly to establish itself in its new surroundings. It is important that a transplanted tree should have the same aspect as it did originally. Hence, before moving, it is usual to mark one side of the tree with a dab of whitewash to serve as a guide.

11. THE WINDOW-SILL BEAUTIFUL
(Pelargoniums and ampelopsis)

Making Woods & Shrubberies. The trees most generally employed in the making of woods are the fir, pine, beech, birch, oak, larch, and, to a smaller extent, the elm. This latter tree has fallen into considerable disrepute, especially for belts or avenues overhanging roadway or path, where it is often a considerable source of danger. This is owing to the fact that for some reason, unknown up to the present, heavy branches, apparently sound, have a habit of breaking off suddenly and falling to the ground without warning.

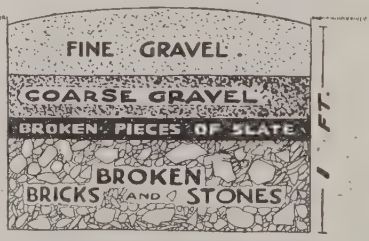
Oak plantations are, in the fulness of time, the most profitable of any, but the reason that so little young oak is laid down at the present day is that it is of very slow growth, and few landowners are prepared to lock up the capital entailed in the establishment and maintenance of oak-woods.

The system which has been found to answer best in making a plantation is to employ nursery-grown plants from two to three years old. These are inexpensive, ranging in price from 5s. per thousand

for the cheaper sorts of firs up to 30s. per thousand for oak and other choicer trees. Opinions differ as to the best distance apart at which to plant these young trees, but a good all-round rule is to allow a space of 5 ft. every way between them. It is usual to "nurse" trees of slower growth, such as oak, by planting a quick-growing timber, such as larch, between them. By the time the oak is sturdy enough to take care of itself, the larch may be thinned out and cut down, if it is not desired to retain it.

Some of the tenderer growing firs are often "nursed" in a similar manner, but there is a simpler way in dealing with this variety of tree. This is to sow the ground, when planting the young firs, with seed of the common gorse, which, being a very rampant grower, speedily affords all the protection needed. Care must be taken not to let it go too far, however, or the gorse may choke a large number of the young conifers. Many firs have a tendency to develop what are called side breaks. These are shoots which appear near the top of the tree, so that instead of tapering away gracefully to a point, as it should do, the centre stem breaks away in three or four directions, not only destroying its symmetry, but greatly lessening its commercial value. These side breaks should be cut off in the early stages of growth.

Where not to Plant Trees. Much care must be exercised as to the position in which young trees are planted. The gardener who fails to look far enough ahead is apt to place them where, although they are very pretty and effective for the time being, they will be the source of great trouble, say, fifty years hence. Trees should never be planted quite close to a house. First of all there is a danger that the roots may spread sufficiently to injure the foundations of the building; secondly, if the house be a low one, there is risk of damage from the dripping of the rain upon the structure as it falls from the leaves and branches; and, thirdly, the presence of big trees near a house interrupts the free circulation of air, and consequently makes the place damp and unhealthy.



12. MAKING A GRAVEL PATH

It is not wise, either, to plant a tree quite close to the edge of a path, for, as it grows older, it will be found necessary either to alter the course of the path or remove the tree.

Making Hedges. A living hedge is always better than a dead wall, and wherever they can be used in gardens in the place of dividing lines of wood or brick, hedges should certainly be planted. Unfortunately, practically all the trees which go to form good hedges are of slow growth, and take a good many years to form a substantial barrier. The quickest growing of all hedge plants is the privet, and this is probably why it is seen so much in every little suburban front garden. At its best it forms but a straggly barrier, and where, owing to circumstances, it cannot be dispensed with, its ugliness may be redeemed by employing one of the variegated sorts. Plants about a foot in height should be used, and they should be put in in the autumn or spring, at a distance of about 9 in. apart, or closer, to form a thick hedge.

The best hedge of all is the holly hedge, but this is one of the slowest to attain respectable dimensions. Plants 2 ft. in height are the best to begin with, planted from 1 ft. to 2 ft. apart, according to their size. They should not be trimmed for at least two years after planting. An old holly hedge forms a barrier that nothing can get through, especially if it be clipped regularly.

The ordinary hawthorn hedge requires practically the same treatment as the privet, though, if it is not cut back within a year or two after planting, it is apt to get very "leggy," the lower part being nothing but a collection of stems.

A yew hedge is probably, next to the holly, the densest and most compact, provided it is clipped regularly in the early spring, before the young growth commences [10]. It should, however, only be used inside a garden, and not to form a boundary by a road or field, or any other place where horses or cattle will be likely to get at it, on account of its poisonous nature.

A Hedge of Sweetbriar. One of the most charming garden hedges, though not a boundary hedge, may be formed with sweetbriar. Though this is very little used generally, it makes the most fragrant of all hedges, and deserves to be much more widely known than it is for this purpose. It can be planted at any time when the roses are being planted, and can always be clipped into a neat, compact shape. This is quite hardy and simple for town use, and is full of perfume during the summer months, in direct contrast to the privet, which, at this time of the year, bears evil-smelling flowers of a dirty white colour.

Near the seaside the euonymus makes a splendid hedge. Particularly is this the case on the South Coast, most of the favourite Sussex watering-places having excellent examples of what can be done with this plant for hedge-making. The tamarisk and the sea buckthorn are also useful in these situations.

During the early years of a hedge's life, it is necessary to watch the young plants very closely, and remove all dying or weakly specimens, otherwise, when the hedge attains maturity, gaps where weakly plants have been will be disclosed.

In clipping hedges, no matter of what nature, they should be cut wedge-shaped, to a certain extent, the narrowest part being at the top. In this way the lower portions are not overshadowed, and thick growth at the base is encouraged.

Walks and Lawns. The making of walks and lawns, and the preparation of formal beds for the latter, are branches of gardening which have to be carried on in such near relation to each other that they should be studied simultaneously.

Most gardens have too many walks. In public parks, certainly, a large number of paths is necessary, because it is only by providing this sort of accommodation for them that a crowd of sightseers can be kept within bounds. No such precaution is necessary, however, in a private garden, where the majority of the walks should be grass ones, prepared and looked after in the manner recommended for lawns. It is impossible to lay down a hard and fast rule as to where a gravel path should be put, as conditions differ in practically every garden of decent size. The carriage drive, of course, must be gravel, so must the main walk to the kitchen garden, the one to the glasshouses, and others which are being tramped over every

minute of the day. An economy, both of time and labour, is effected by making most of the others grass walks.

Unless the exigencies of space compel, it is better never to make a gravel walk a perfectly straight one. Such a path, running hard and uncompromisingly out in the perspective, is rarely a pleasing sight, even if fringed by the choicest flowers. At the same time it is absurd to make a path wriggle all over a garden for the mere sake of doing so.

Nowhere in the world are such lovely lawns to be found as in our own gardens, and few things are more refreshing to the eye, or more beautiful, than an expanse of smooth, unbroken turf. This fact should be borne in mind when laying out a garden, and care should be taken to keep all beds near the edge of a lawn, and not to go dotting them at regular intervals all over the turf just for the sake of symmetry. The aspect of such a garden is sure to be hard and unnatural.

How to Make Walks. The first step in the making of a walk or path is to map out exactly where it is to go. In the case of a large garden, a plan must be prepared on paper first, otherwise confusion will invariably result; but with a small garden this is not necessary. Then the course of the path must be traced out on the ground by means of cords, to which, at intervals, small pegs are attached. These strings and cords are one of the gardener's most important tools in the early work on the ground, as they serve to outline every bed and border, and determine the width and direction of every path.

When these points are satisfactorily settled, the soil, to the depth of about 1 ft., should be dug out all along the course of the proposed path, and carted away. Needless to say, it will be much appreciated elsewhere. At the bottom of the trench thus made a layer of broken bricks and large stones should be distributed in as level a fashion as possible, to the depth of 6 in. or 7 in., for the purpose of drainage. They should be well crammed down, and covered with 2 in. or 3 in. of coarse gravel, which must be well rolled in. Upon the top of this the final layer of fine gravel rests, to the depth of 2 in. or 3 in. In building up the path the surface should be made a little higher at the middle than at the sides [12].

If available, a layer of pieces of broken slate, about 2 in. in thickness, should be placed between the broken brick layer and that of coarse gravel, as worms cannot penetrate this material, and unsightly worm-casts are prevented. Much rolling is necessary when a path is first made, as otherwise the top layer will never become hard and firm.

When once a walk or path is made, there is always

13. WATERSIDE PLANTS, KEW GARDENS

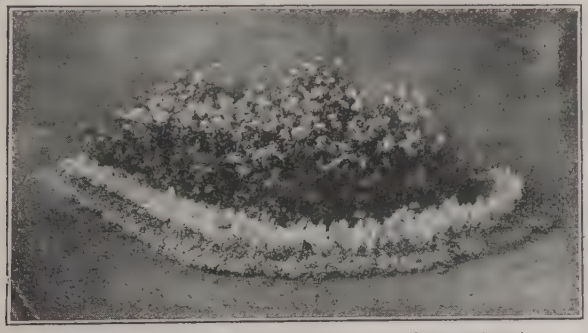
the task of keeping it free from weeds to be considered. By far the most efficacious way is, of course, to pull up the weeds by the roots as fast as they make their appearance. There are many chemical weed-killers on the market, but they require very careful handling, as not only do they kill weeds, but everything else with which they come in contact. A dressing of salt is a pretty effective weed-killer, and an application of boiling water serves a similar purpose.

A stone path is a good path if properly constructed, and is always practically dry. In constructing such a walk, proceed as indicated for gravel walks, until the layer of coarse gravel is laid and rolled. Upon this should be laid just an inch or so of soil, and in this, embedded roughly, shaped pieces of flat sandstone, in the form of an irregular mosaic. Old paving stones, such as may be procured from any contractor's yard, and broken up with a sledge hammer into pieces of any size from 6 in. to 2 ft. across, are excellent material for the purpose. As these are embedded, a little soil should be pressed into the chinks between each piece, and in these chinks stonecrops and mosses may be planted. These will quickly establish themselves, and form a very pleasant walk in the course of a season or so. Such stone walks are comparatively rarely met with, and the present vogue of the rock garden which uses up a large quantity of broken sandstone makes their establishment somewhat expensive. They are very artistic and effective.

The Making of a Lawn. There are two ways of making a lawn—by turfing and by seed. In places where, in forming the garden, good turf has been cut off and stored from parts of the ground when levelling is going on, it may well be replaced; but where an entirely new lawn has to be made it is better to employ grass seed than to purchase turf and lay it.

Before sowing, an operation which is best carried out in the springtime, the ground should be well dug over with a spade, all lumps being broken up with a garden fork, and afterwards gone over with a rake, to ensure that the surface soil is nice and fine, and, moreover, free from stones. Then go over it with a light roller, being careful, especially in the case of a tennis lawn, to see that it is quite level.

As soon as the surface is nice and smooth, it is ready to receive the seed. The regulation quantity of seed, as recommended by all the leading authorities, is 1 lb. of seed to every 16 sq. yd. In other words, a bushel of grass seed will sow



14. A MIXED BED (Mostly *Lilium speciosum rubrum*)

an area of 400 sq. yd. Two apparently trivial but really important points must be observed when sowing a lawn. There must be no wind, and the sower must not wear high-heeled boots. Grass seed is very light, and even a moderate breeze would blow it into uneven patches as it leaves the sower's hand, while high heels would dig into the ground, in its unsettled state, and disturb the level. Careful gardeners wear flat pieces of wood, with straps to fasten over the boots, when sowing.

When the seed is sown it should be covered by just the slightest covering of loam or sand, and rolled lightly. If the soil be a heavy clay, the covering of sand will be the best, while if the soil is in itself a light one, it will benefit more by the sprinkling of loam. This must in turn be rolled, but lightly, otherwise the delicate little blades of grass might find difficulty in forcing their way to the surface. Where there is any danger of the seed being attacked by birds, black threads should be stretched at intervals across the ground, 2 in. or 3 in. above the surface.

The new lawn should not be rolled or swept until the grass is 2 in. or more in height, when it may be rolled lightly and swept gently. A lawn mower should never be used to a new lawn, as it is apt to tear the tender young grass up by the roots. The scythe is the proper implement to employ for this purpose. Scythe mowing should be carried out early in the morning, when the dew is on the grass, as the scythe works best at these times. The mowing machine, which may be used when the summer comes and the grass has got well established, works best when the ground is dry, and may therefore be employed at midday. To ensure a good velvety turf, a lawn should be well mowed and rolled at least once a week. Daisies, dandelions, and other weeds should be rooted up without mercy by the instrument known as a daisy fork.

15. A PINK-FLOWERING WATER-LILY (*Nymphæa rosea*)

Carpet-beds on Lawns. A carpet-bed is a bed formal in outline, and also in the nature of its contents, which consist of dwarf plants of a similar height, arranged in a set pattern, sometimes to form a word or motto, or else according to a geometrical plan, so that they resemble a part of a pattern or a carpet. Carpet-beds are not by any means the only sort of beds that can be made on lawns [14]; but as lawns are the only place for them, and their preparation is really part of the garden design, it is best to deal with them here.

Many gardeners maintain that to arrange plants in such a formal way is an outrage upon Nature, and ought to be tabooed; while, on the other hand, there are many gardens in the kingdom where carpet-bedding is carried to excess, and the only effect is a hard and ugly one.

The best way is to strike an intermediate line, and have a little carpet-bedding, if it be desired, near the house, whence the bedding can gradually get less and less formal, until it merges into the wild garden.

Before making a carpet-bed, the design should be drawn out on paper, and marked with the names of the plants it is proposed to use in each section to give the varying colours. If the bed is to be circular, it is usual to peg out a square on the site, and then cross it with two diagonal strings. Where these strings meet is the centre of the bed. Place a peg there, with a string attached, and, just at the point where the string touches the side of the square tie an old knife, steel point, edging tool, or anything that will cut the turf. Then, by dragging this round the ground, a perfectly circular cut will be made.

Plants for Carpet-bedding. The soil for a carpet-bed should be broken up fine, or sifted, for preference, and a little sand mixed with it, unless the soil is already sandy itself. Before, however, the work can be proceeded with any further it is necessary to prepare the plants which are to fill the carpet beds. These are a class by themselves, and their culture is of the simplest. The pyrethrums, which give gold, pale green, grey, and yellow tints, are grown from seed, which must be sown in a greenhouse, with heat, in early spring, in boxes of sandy soil, and will be ready for putting out in the bed in May, which is quite soon enough, in order to escape the possibility of a touch of late frost. Red and blue lobelia are treated in a similar manner.

Alternantheras are another important family for carpet beds, and their colours range from yellow to red, but cuttings of these must be purchased in the first instance as seed is not readily procurable. These cuttings must be put into sandy soil, and rooted on a hotbed. A hotbed is made in a frame, or frames, in the garden, and consists of a layer of about 18 in. of manure, covered with a good layer of soil. The decomposition of the manure induces heat, and this heat causes the cuttings to take root and thrive. As the spring progresses, the glass top of the frame should be raised during the day to allow the young plants to gradually harden off. Other prominent carpet-bedding plants are iresines, antennarias, stonecrops, and Herniaria glabra. In preparing plans for carpet beds, particular attention should be given to the harmonious blending of the colours of the plants.

When the plants are ready for putting out, the pattern of the bed must be carefully mapped out on its surface in silver sand, and the young plants put in, about 2 in. apart, with great accuracy, commencing at the centre and radiating outwards.

A carpet bed, carefully prepared, will last on into the autumn until the early frosts spoil it. It should then be cleared, and, in order to avoid ugly brown beds during winter, they should be planted with dwarf evergreens and bulbs of snowdrop, crocus, and early-flowering daffodils, the culture of which will be dealt with elsewhere.

The Rock Garden. Rock gardens, as at present constructed, are, generally speaking, capable of a great deal of improvement, and in preparing one its true purpose should not be lost sight of. This purpose is, in the main, to enable the choicest Alpine and other mountainous plants to be grown in this country under as natural conditions as possible. Therefore the piling up of masses of rock and stone with no thought for the needs of the plants that are to adorn them is not at all likely to produce satisfactory results. It is most important to remember that the plants, and not the rocks, represent the most striking part

of the scheme, and the introduction of vases, statues, and other eccentricities into a rock garden is not desirable.

The spring is the best time of the year in which to begin making a rock garden, and a sunny position in the garden is the best spot at which to construct it. It may be of any size, but should be irregular in shape, though there is no need to go out of the way to make it curious in this respect. If the soil is not good and deep at the spot where it is proposed to construct the rock garden, the ground must be dug out to the depth of 18 in. or more, and a good mixture of peat, loam, and sand put in its place. This bed of soil should be raised well above the level of the surrounding ground, or a picturesque effect will not be obtained. The so-called rocks may be pieces of any kind of stone which is common to the district. In fact, in towns, many effective little rock-beds can be built up by employing pieces of ordinary sandstone pavement, broken up into irregular shapes. Sufficient for the purpose can generally be procured at a nominal price at any builder's yard.

The whole secret of successful rock gardening is this: Plants suitable for growing under these conditions require full exposure to the sun, though at the same time they must have plenty of moisture at the roots. Hence the real use of the rocks is to act as a shield and prevent the evaporation of the moisture so essential for the well-being of the plants.

There are some shade-loving rock plants, but they are comparatively few in number compared with the others. It is impossible to lay down any hard and fast rule as to how pieces of rock should be arranged in every garden—so much depends upon position and surroundings in each instance. Individual taste must be brought to bear upon the matter, taking care to avoid all trace of formality and "building" [16]. Rock gardens should never be made near trees, as their shade destroys the very object with which it was constructed.

When first constructing a rock garden it is best to put a few pieces of rock in the most prominent positions, and then insert the plants, gradually embedding the minor pieces of rock in the soil as the planting goes on. In this way not only is a more natural aspect assured, but the plants are more securely rooted than they would be if the rocks were arranged methodically at first, and the plants tucked in between the crevices afterwards. One or more members of the following families go far to make up a representative collection for the sunny part of the rock garden: Alpine harebell, orchis, Alpine anemone, stonecrop, allium, androsace, antennaria, arnebia, armeria, chionodoxa, colchicum, daphne, Alpine pink, sea-holly, dog's-tooth violet, geum, iris, leucojum, lithospermum, muscari, pentstemon, Jacob's-ladder, potentilla, primula, saxifraga, sempervivum, sternberga, trillium, trollius, foamflower, and viola. Those which thrive best in shady situations are the lady's slipper (hardy cyrpripedium), gentian, ranunculus, epimedium, hepatica, and iberis.

16. A WELL-MADE ROCK GARDEN

Water Gardens. It is quite possible to construct water gardens in places of modest dimensions; in fact, there are many instances in which water lilies have been successfully grown through no more ambitious medium than a half-barrel sunk in the ground. The orthodox method of making a pool in a country garden is to dam a stream at some convenient spot and form a pond of the overflow.

Where there is no stream at hand, the water must be brought to the spot by pipes, if ambitious water gardening is to be attempted. First of all the piece of ground which it is proposed to transform into a water garden should be dug out to the depth of 3 ft. or 4 ft., and the soil carted away. The edge of the hollow thus made should be purposely left irregular in shape, as, if it is cut square or circular in form, the effect is formal and unpleasant. A layer of clay about 1 ft. in thickness should then be spread over the bottom of the basin, and thoroughly beaten into the ground. This operation of beating is most important, as it is to render the basin watertight, and if carelessly done the water will leak away. On top of the clay a layer of good loam from 6 in. to 9 in. in thickness should be spread, and the water may be let in.

Water Lilies in the Small Garden. Even where the only water available is the half-barrel just alluded to, it should be sunk well below the level of the ground, and the formal edge broken up with a few groups of moisture-loving plants. The best form of barrel to employ is a petroleum or beer cask. It should be sawn in two, and charred on the inside so as to remove all traces of oil or alcohol. It should then be pitched on the outside, after which it is ready to be plunged into the ground. At the bottom of the barrel place a layer of good stiff clay, and on top of this a few inches of a compost of two-thirds good fibrous loam and one-third old, well-decayed leaf soil. This should leave ample room for about 1 ft. of water, which

can be poured gently in after the water lilies have been planted.

Water lilies can be grown quite easily in this way even in suburban gardens, as they will thrive better in a stagnant pool than in running water.

Planting water lilies in the water garden is merely a question of getting an openwork basket, filling it with soil, and inserting the tuber. A stone should be tied to the basket to prevent it being washed away, if the water has a current. Water lilies thrive best when fully exposed to the sun, and the best time for planting is during the months of April, May, or June. The following nymphæ are the best six to plant: Alba, Rosea [15], Froebellii, Laydekeri, Odorata, and Robinsoni. Other flowers which should be planted in the water itself are nuphar (often mistaken for a water lily), the Cape pond-flower, buckbean, arrowhead, reed mace, arum lily, bullrush, and the water forget-me-not.

As the banks of a water garden are sure to be damp and marshy, they should be liberally planted with moisture-loving things in the springtime [13]. Among the best of such plants are the Japanese iris, marsh marigolds, globe flowers, several varieties of the hardy bamboos, day lilies, American swamp lily, royal fern, and several of the arundo, or reed family.

The Wall Garden. The wall garden is almost a thing of the past, except in old-established places, notably those in the West of England. This is probably due to the fact that brick walls and wooden fences have practically superseded stone as boundary lines.

A good wall garden is, however, always a charming sight, and may, for the sake of illustration, be called a vertical rock garden. The whole system of wall gardening consists in planting suitable subjects between the chinks and on the top of stone walls, taking care that such chinks have sufficient soil to enable the plants to live. The best of all these plants is, naturally, the wallflower itself (*Cheiranthus cheiri*), which is sometimes found self-sown on the sides of disused quarries, chalk pits, and in other similar situations. It seems to thrive on practically nothing, growing almost on the bare rock itself. The majority of wall plants are rock-garden plants as well, though their number is necessarily limited, as most rock plants are deep-rooting subjects. Varieties of the following are among the most suitable: Alyssum, arabis, erodium, gypsophila, linum, polypodium, saxifraga, sedum, and sempervivum.

Climbing Plants. One of the principal features which make or mar a garden are climbers. This is particularly noticeable in gardens of modern formation, which are usually those attached to ugly houses. So few modern-built houses are handsome in appearance that it is a good thing to clothe them, as far as possible, with climbing flowers and plants. It is not only against the walls of houses that the climbing plants are both beautiful and desirable, but out in the garden itself, where summer-houses, arbours, covered walks (which are known as pergolas), walls, fences, old tree stumps, and many unsightly objects may be improved by their use. In many cases, indeed, climbing plants may be allowed to grow over living hedges and up tree trunks, though in this last capacity they should be employed in moderation; if used to excess, the result often gives the impression of careless gardening. The climbing plants most sought after are, naturally, those varieties of the rose which have this habit. They will thrive in almost any aspect, though, naturally, such good results cannot be expected on a wall facing north as in more sheltered situations. In a loamy soil, which is about 2 ft. deep, however, they would do well, even in many town gardens. It is a mistake to prune climbing roses too freely; nor should they be nailed against the wall at every few inches, as if they were undergoing a species of crucifixion, but only given such support as is absolutely necessary, so that they can make their way upwards as naturally and gracefully as possible. This remark applies to practically all climbing plants. The best of the climbing roses are: Reds—Crimson Rambler, Cheshunt Hybrid, and Waltham Climber. Yellows—Blairii No. 2, Gloire de Dijon, Bouquet d'Or. White—Aimée Vibert and Niphetos. Pink—Climbing La France and Pink Dorothy Perkins. Apricot—William Allen Richardson, Rêve d'Or, Madame Berard.

Clematis and Creepers. Next in importance to the rose as a climbing plant is the clematis. Most of the varieties are grafted on wild clematis. The most useful hybrid for general purposes is Clematis Jackmani, the large purple flowers of which are so often to be seen in town gardens. It has a variety—Alba—whose flowers are equal in size and number, and white in colour. The clematis flourishes well in a light soil, and flowers freely from May to July.

Other spring and summer flowering climbers include the wistaria, white jasmine, and the honeysuckles, while seed of the common climbing nasturtium and canary creeper, sown at the bottom of an arch or arbour during the month of April, will cover it in a month or two. Being annuals, sowings of such plants must be renewed every year.

For exposed situations there is, of course, nothing to equal the common ivy, or one of the variegated sorts. This has the advantage of being evergreen, and is consequently in evidence all the year round. The Virginian creeper is noteworthy for its beauty in autumn; but after the leaves fall it presents a very untidy appearance. A much neater climber of this class is Ampelopsis Veitchi.

Winter Flowering Climbers. There are three climbers which are of inestimable value, as they flower in the winter time. Two of these are admirably adapted for town gardens. The best is the yellow-flowered jasmine, which, though its stems are bare at the time, is covered during the most unfavourable months of the year with a shower of bright, yellow blossoms of diminutive size, which make a brilliant contrast with the dark-brown stems of the plants and the brick walls.

The second perfectly hardy winter climber is the pyracantha, which it is hardly accurate to describe as "flowering," as it is its bright orange-red berries and rich dark evergreen foliage which render it valuable during the dark days. It thrives with equal vigour in any sort of soil.

In favoured situations the winter-sweet (*Chimonanthus fragrans*) may be grown on a south wall. Like the jasmine, its flowers are borne on bare stems. It is particularly sweetly scented, and if the flowering shoots are cut and floated in a shallow vessel of water, they will diffuse their fragrance through a dwelling-room for many days. No harm is done by treating the shoots in this way, as in the ordinary course of events they would be pruned after flowering. Winter-sweet, however, is not suitable for town gardens.

H. H. HAVART

History, Nomenclature, and Classification of Artificial Dyestuffs, with their Properties, and Modern Processes of Dyeing.

ARTIFICIAL DYES

Artificial Dyestuffs. Although the dyer's art is prehistoric, he has been dependent until little more than half a century ago entirely upon natural colouring matters, and of these comparatively few only of the immense variety provided by the animal and vegetable realms have been used in dyeing. The reason is that the natural dye in some cases depends for its existence on the life of the plant or animal whose vital processes have produced it, in others that it resists every attempt to extract it, or that when extracted it is too fugitive and unstable on textile fabrics to be of any service. Although some of the usable natural dyestuffs are of an excellence hardly yet surpassed in some directions by artificial products, as a rule these latter are much simpler in use, a matter of first importance to the dyer. Hence, short as the life of the artificial dyestuffs has been, they have driven the majority of their predecessors from the field which they have occupied alone for so many centuries, or at least have greatly restricted the scope of their utility. Being definite substances, and therefore always possessing the same properties, they are simpler and more certain in their application than the natural dyes.

Although of such recent origin, the manufacture of artificial dyes has developed at a rate probably unparalleled in the history of industry. It would probably be a safe assertion to say that the number of patents taken out for coal-tar products exceeds that obtained for any other class of invention.

History of Artificial Dyestuffs. In April, 1856, William Henry Perkin, who died in 1907, made a substantive dye for silk known as Perkin's mauve. He was trying to synthesise quinine by oxidising aromatic bases. He found that the bluish precipitate produced by the interaction of aniline and bichromate yielded a splendid violet solution with alcohol, and the dye was obtained by evaporating the tincture. The result was British Patent 1984 of 1856, taken out after consultation with Pullar, the Perth dyer. In partnership with his father and brother, he erected a factory at Greenford Green in 1857, and began to put Perkin's mauve upon the market in the following year. Aniline was thus the first coal-tar product which yielded a commercially useful dye.

Perkin's dye was first sold in this country by the name of Tyrian purple, but on the Continent it was called Perkin's violet or mauveine. It was largely used for silk sunshades, and was until lately used for paper for postage stamps.

Perkin's success set chemists at work on coal-tar. The next discovery was magenta, obtained by Verguin in 1859, by acting on aniline with stannic chloride, and in the same year the second artificial dye factory was erected by Geigy & Co., at Basle. The French patent law of 1844 prevented much being done in France. Hence, when Durand and Gerbert Keller introduced the use of mercury salts in the preparation of magenta, they went to Basle.

In 1860 magenta was £30 a pound, and this and mauve were the only artificial dyes at that time made from coal-tar. In that year, however, azuline, the first coal-tar blue, was discovered, and the method of preparing magenta by oxidising a mixture of aniline and toluidine with arsenic acid was invented by Medlock, and brought the dye into commercial use. Two important events mark the 'sixties—the perfection of aniline black by Lightfoot in 1863, and the synthesis of alizarin, one of the colouring matters of madder, by Graebe and Liebermann, and also by Perkin, in 1868, both epoch-making achievements. Graebe and Liebermann thus effected the first synthesis of a natural dyestuff. Their process was not, however, a commercial one, but Caro and Perkin soon introduced the sulphonating process still employed. A large number of new dyes was soon added to the small list then existing, and the new industry was fairly launched.

Synthetic Dyes. It is impossible to devote sufficient space to give more than a vague idea of the methods of colour manufacture [see page 5198]. The methods whereby synthetic dyes are prepared from the raw material or from the intermediate products which have to be made from the former as a preliminary step may be classed under two categories—substitution methods and coupling methods. It is by substitution, too, that the intermediate products are prepared. Substitution means replacement of part of the molecule of the initial product by a part of the molecule of some other substance. Coupling means simply the combination of two molecules which, although able to exist by themselves, have nevertheless certain "unsaturated" affinities which will enable them to unite into a single substance.

Nomenclature of Dyestuffs. An aniline was the first coal-tar dye discovered, and since the days of Perkin's mauve the British public have spoken of all artificial dyes as anilines. The alizarines, however, are not anilines, and the discovery of this large group was very early in the history of coal-tar dyes. The first sulphur colour was not even a coal-tar dye, and petroleum residues are used in some places, Russia, for instance, in place of coal-tar as a raw material. The correct term, therefore, unless we are speaking specifically of an aniline, is "artificial organic colouring matter," which completely fills the field.

Artificial dyes, to content ourselves with a shorter term, with some exceptions, are definite chemical substances, but the makers, for good and sufficient reasons, put them on the market under a commercial or "trivial" name. It is obvious that it is easier for the dyer to ask for Bismarck brown than for hydrochloride of benzene-diazo-phenylene-diamine, and this is simplicity itself as compared with the chemical names of some of the dyestuffs. The only inconvenience is that the same dyestuff is often on the market under a variety of names. That already instanced was called Bismarck brown for obvious complimentary reasons by its German discoverer, Manchester brown by the Manchester firm who improved the method of manufacture, English brown possibly by way of protest, phenylene brown from its composition, leather brown when it was found to be suitable for that material, and cinnamon brown because of the rich, reddish brown shade it gives.

As a rule, the commercial name suggests the colour produced by the dyestuff (diamond yellow), and in some cases the particular tone or tint (turquoise blue). It frequently gives an indication of the chemical origin of the dyestuff (resorcin brown), or claims special properties of resistance (milling yellow), or, as in the case of night blue, of remaining unchanged in an artificial light. Very frequently the recommended use is indicated, as, for instance, wool scarlet, union black, cotton blue; or the way in which it is to be used, as, for instance, chrome green, spirit blue.

Names indicating Colour. The names indicating colour have been taken from all sources. From flowers we get primuline, rhodamine, and rosophenin, from the Greek and Latin respectively for a rose, mimosa, and others. A number of dyes commence with a Greek or Latin name meaning or suggesting a colour: chrysamine, chrysoidine, auramine (golden), citronine (lemon), cyanol, cyanine (blue), eosine, eosamine (*eos*, the blush of dawn), flavine (yellow), irisamine (*Iris*, the rainbow), nigrosine (black), pyramine (fiery), chlorine (yellow), and others. Uranine comes from uranium, whose compounds show fluorescence, now said to be due to radium, and fluorescent blue and fluoresceine convey the same idea of a changing colour effect. Some names are frankly popular and topical, as, for instance, Magdala red, Congo red, Guinea green; and others, as in the case of Perkin's mauve and Meldola blue, commemorate the discoverer.

The letters following the names are not meaningless; as a rule they indicate the particular tint. Thus brilliant Congo R gives a frank red, while brilliant Congo G (*gelb*, German, yellow) has a yellowish tinge. The degree is shown, a sin the case of benzopurpurines, which are sent out in four "brands," ranging from B, a slightly bluish red, through 4B and 6B to 10B, a very bluish red.

Classification. Classification is essential in the consideration of any subject, but with the artificial dyes, as with all other great groups, the sub-classification is difficult, and, on whatever principle we proceed, is only a makeshift at the best, though a very necessary one. In classifying the artificial dyes, we may consider their chemical composition, their method of application, or their effects upon different textiles. It seems best to arrange them with some reference to all these points, and we propose to make six main classes as follows: (*a*) Direct Cotton Colours; (*b*) Acid Colours; (*c*) Basic Colours; (*d*) Ordinary Mordant Colours; (*e*) Acid Mordant Colours; (*f*) Insoluble Colours. It must, however, be noted that there are dyes which belong to two or even three of these classes.

Direct Cotton Dyes. These dyes are so called because they dye vegetable fibre without the assistance of a mordant. It is evident, therefore, that they dye other textiles direct, for cotton has less affinity for dyestuffs than wool or silk. With the exclusion of the sulphur dyes—which are not classed as direct dyes, and in this course it seems best to take with the insoluble dyes—the first direct cotton dye discovered was Congo red in 1884.

The direct cotton dyes are compounds of various colour acids with alkalies, and are, therefore, all decomposed by acids. Unless, then, the colour acid set free happens to have the same colour as the original dye, the shade produced is not fast to acids. Most of the group are decomposed by hard water with precipitation of a lake, and therefore the water for the dye-bath should be softened for use.

The direct cotton dyes used directly are not very fast, as a rule, especially on cotton and linen, but their resistance to external agencies can be greatly increased by treating the goods in various ways after dyeing. Sulphate of copper and chromium compounds are largely used for this purpose, and many of the direct cotton dyes can be fixed by diazotising.

The direct cotton colours are not much in vogue for wool, which can be more cheaply coloured by means of acid dyes, but for mixtures of wool and cotton they are used in a neutral bath.

Accelerating and Retarding Agents. Every member of the class requires an assistant in the dye-bath, either to accelerate or retard the going on of the dye. For the former purpose Glauber's salt or common salt is employed; for the latter, carbonate of soda or even caustic soda or soap. It is very common to use both a retardant and an accelerant. Thus in many cases, the first part of the dyeing is done in the presence of carbonate of soda, and Glauber's salt is added to the bath later. Soap is often used with Glauber's salt or common salt for mode shades.

The direct cotton colours are dyed on wool at the boiling point, and in a neutral or alkaline bath, and with the same assistants as cotton. Some of them can be dyed in a bath made slightly acid with acetic acid, but even with these a neutral bath is preferable. However, the property of dyeing in an acid bath is made use of in dyeing mixtures of wool and cotton. The use of acids tends to make wool take a redder shade than cotton does under the same circumstances, and this prevents level dyeing of mixtures.

In the case of silk, the dye-bath is best made with soap broken with acetic acid. An after-treatment exactly as for cotton is required if great fastness is a desideratum, although the direct cotton colours are faster on either wool or silk than they are on cotton.

The direct cotton colours can be combined freely in the same bath, so that any possible variety of shade is easily procured. Whenever practicable, however, those dyes should be selected for mixing which require the same assistant. If this cannot be done, the assistant must be chosen with regard to the dye which is added in largest quantity. Baths of the direct cotton dyes very rarely exhaust, and can be kept standing, reinforcing them with more dye and Glauber's salt when each fresh batch of goods is put in. The shorter the bath—that is, the smaller the excess of weight of the dye-bath over that of the goods—the better the exhaustion. Large amounts of assistants also favour exhaustion, which, of course, depends on the affinity of the fabric for the dye, so that, other things being equal, the bath will exhaust better with wool or silk than with cotton. A strong bath has the advantage, in the use of the direct cotton dyes, that it gives deeper and fuller shades. Hence it should not be diluted by heating with direct steam. The heat should be applied with a closed coil. It is a good plan to allow the goods to cool for some time before lifting them. This conduces to uniformity of shade, which is to some extent imperilled by the use of strong and short baths. An average length of bath is from 200 to 250 gallons per 100 lb. of goods.

An important property of the direct cotton colours is that they act as mordants to the basic dyes, so that useful colours can be got by topping; that is, by dyeing first in a bath with direct dyes, and then "topping"—*i.e.*, re-dyeing—with a basic

colour. The lakes formed, however, are decomposed at about 160° F., so that the topping bath must be below that temperature. The diamines brought out by Cassella in 1889 belong partly to this class. Some are diazotisable colours.

As regards the after-treatment, bichromate of soda or sulphate of copper, already alluded to in this connection, are the usual agents, but diazotising is often resorted to. In this process the goods, after dyeing and rinsing, pass through a bath containing 1½ per cent. to 2½ per cent. of sodium nitrite and 5 per cent. to 8 per cent. of hydrochloric acid. This bath must be kept cold. It was at first considered necessary to use ice, hence these dye-stuffs were known as "ice" colours. Development follows with one of the numerous developers upon the market. Beta-naphthol—1 per cent. dissolved in caustic soda—is perhaps the most commonly used developer. This diazotising process affords great scope for shading and dyeing to pattern, for mixtures of azotisable and non-azotisable dyes, and a mixture of developers, can be used on the principle that the final colour depends partly upon the developer.

Most of the garment cloth now on the market is a union fabric—that is, a mixture of wool and cotton. This is dyed in the piece with direct cotton colours, the dye-bath being made simply with colour and Glauber's salt. Some direct dyes do not go equally on the two fibres. Others require management of the bath, the wool taking most colour at the boil, whereas the cotton continues to take it in the cooling bath. The household dyes sold in packets are selected direct cotton colours.

Basic Dyes. These are the oldest coal-tar dyes known, inasmuch as Perkin's mauve is one of them. Safranine was discovered in 1863, and Bismarck brown—the first azo dye—in 1864. In constitution the basic dyes consist of salts of colour bases. They are direct dyes for woollens and silks, and adjective dyes for cotton. Most of them are soluble in water, and all in spirit. A few of them, such as auramine, are decomposed by hot water, and they should not be used with hard water, which precipitates and wastes them, as it does the direct cotton colours. They are brilliant colours, but not remarkably fast. On cotton they are usually dyed on a tannin and tartar emetic mordant. Iron salts are sometimes substituted for the antimony salt, or Turkey-red oil or soap mixed with acetate of alumina. If the tannin process is adopted, a very short tannin bath at about 170° F., and containing about 5 per cent. of tannin, is used, although some require more tannin for several hours. The goods then pass direct into a solution of from ½ per cent. to 2½ per cent. of tartar emetic, according to shade. This bath is kept standing, and is reinforced as may be necessary. If difficulty is found in getting level shades, as occasionally happens, the goods should be mordanted after, instead of before, dyeing. In dyeing dark shades it is a good plan to use decoctions of natural tannins, such as sumach, as the natural colouring matter present in the solution saves some of the artificial dye. Yet another method of mordanting is to dye first with a direct cotton colour of the same shade.

On wool the basic colours are now of comparatively small importance, as the acid dyes have supplanted them to a large extent. The basic dyes are always dyed on wool in a neutral bath. Acetic acid is put in if the water is hard, but merely in sufficient quantity to soften the water and prevent the lime in it from throwing down the colour base, whereby the shade would be made unlevel and spotty. Too much acetic acid retards the exhaustion of the bath. Glauber's salt is sometimes used. Silk is dyed in a neutral bath, as a rule, but it may be slightly alkaline or acid without disadvantage. As is usual in silk dyeing, a soap-bath is commonly employed. The goods are entered lukewarm, and the bath is gradually heated to about 200° F., at which temperature the dyeing is finished. The basic dyes are faster on silk than on cotton or wool.

The Hoechst Janus dyes belong to this group. They were introduced in 1897, and are azo dyes, which are remarkable for dyeing cotton, wool, and silk direct from acid baths.

Acid Dyes. These are salts, and the colour has to be liberated by the addition of acid to the bath. In the case of wool, the fibre may be soured before entering the bath. An average recipe for wool is: dye-stuff, ½ per cent. to 6 per cent.; Glauber's salt 10 per cent.; sulphuric acid, 4 per cent. Enter hot, raise to the boil, and boil from an hour to an hour and a half. Their first representatives were fluoresceine and its bromine derivative, eosine, both discovered in 1874. When first put on the market by Bayer and Caro, eosine was sold at £18 per pound. The acid dyes are mostly soluble in hot water. They can be dyed on cotton with the ordinary mordants, but they are not much used. The acid dyes have less tinctorial power than the basic dyes. The average amount of dye needed for a fairly full shade may be put at 3 per cent.

On silk the acid colours are used exactly like the basic, except that the baths are usually made more acid, and that lower temperatures—say, 140° F.—are employed to check any tendency to want of uniformity. Silk has little affinity for the acid dyes. It is as substantive dyes for wool that the acid dyes find their chief application.

Some of the dyes, such as chromotropes, chrome brown and alizarine yellow, are fixed with chromium fluoride, alum, or bichromate, added either at the end of the dyeing to the dye bath itself or applied to the dyed fabric in a separate vat. A few acid dyes, such as eosine and phloxine, require the use of acetic instead of sulphuric acid, or the resulting shades are wanting in brightness.

The bath made with the acid dyes exhausts well on wool—that is, it parts with almost all the dye and can be run off. If sufficient acid to exhaust the bath has not been added to begin with, the ordinary expedient is to add more towards the close of the operation.

Many garment cloths are now woven with white or coloured "effect threads" of cotton. When dyed in the acid bath these threads do not take the colour, or to such a small extent that it is eliminated in the subsequent washing.

Mordant Colours. This group is divided into two classes—the ordinary mordant dyes and the acid mordant dyes. The latter behave as acid dyes after heating with a metallic salt or oxidation with bichromate of potash and sulphuric acid, with or without the addition of Glauber's salt. The ordinary mordant dyes are substances which have the power of combining with the oxides of various metals, forming insoluble lakes, and the use of these dyes depends upon the formation of the lake upon the fibre.

The general method of the application of the acid mordant dyes is to mordant and then dye the material with them at the boil with sulphuric acid and Glauber's salt, and when the bath is exhausted

to allow it to cool to about 150° F., when the bichromate is added, the goods being lifted the while. The dyeing is then resumed and continued for about half an hour longer. If more than one dye is in use, those should be chosen which require the same mordant.

Mordant Processes. With the ordinary mordant colours the processes may be classed as two-bath and one-bath. In the former the dye and the mordant are used in separate baths, sometimes the dyeing preceding the mordanting and sometimes the reverse. In the one-bath process the mordant and the dye are used in the same bath. The chief mordants used are various salts of iron, aluminium, and chromium.

A highly important class of chrome colours for wool has lately been very largely used which can be dyed in any one of three ways: (1) by mordanting with chrome and dyeing; (2) by dyeing in a single bath with chrome and colour; (3) by dyeing first and after-mordanting with chrome. Some of these give the best results with one only of these three processes. A well-known class of these dyestuffs are known as the metachrome colours.

One of the most important branches of mordant dyeing for cotton is alizarine dyeing. To get alizarine Turkey-red on cotton various methods are employed. The goods are first impregnated with Turkey-red oil, dried, and steamed. They are then dyed with from 5 per cent. to 20 per cent. of dye, and a little acetic acid if the water is hard. They are entered cold, and the bath is very slowly heated to nearly boiling point and kept at that temperature until exhausted. The goods are wrung, rinsed, and dried, and mordanted in a fresh bath, the mordant being selected according to the colour wanted. If the mordanting is to precede the dyeing, the metal must be fixed on the fibre by a bath intercalated between the mordanting and the dyeing baths. One method is, after treatment with Turkey-red oil, to wring the goods, and then dry them at a moderate heat (about 130° F.). They are then given several hours in a bath of basic sulphate of alumina, made by dissolving alum in hot water and adding crystals of carbonate of soda when cold. Add 1 lb. of the crystals for every 4 lb. of alum; then fix the alumina in a bath of chalk or phosphate of soda, and dye. In this process the dye-bath must contain lime.

Erban and Specht were the first to dissolve the dye in a solution of ammonia, fixing with alumina, and this was found to be a useful process. For dark shades aluminic acetate is used and converted into the basic insoluble form by subsequent steaming. For light shades aluminate of soda is used. In this case the steam has to be accompanied by acetic acid to form the basic acetate. Linen is treated as cotton.

Lately the modern vat dyes have come into severe competition with alizarine, which very easily supplanted madder. The old Turkey-red dyeing with this natural dyestuff was specialist work, slow, complicated, and even dangerous.

Mordant Colours on Wool. For wool with the mordant colours a common mordanting bath is bichromate of soda to which a reducing acid, such as lactic, formic, or acetic, has been added. The chromium is deposited on the fibre as sesquioxide, and at once forms the lake when the goods are entered into the dye-bath. About 3 per cent. of bichromate is used for dark shades, less for lighter ones. The amount of acid is rather less. With chromium fluoride, use 2 per cent. to 4 per cent., and 1 per cent. to 2 per cent. of oxalic acid. When alumina is used, the bath is made with 5 per cent. to 8 per cent. of sulphate of alumina, or 6 per cent to 10 per cent. of alum, and 3 per cent to 8 per cent. of tartar. This bath should be rather long (say, forty times the weight of the wool). If there is too much alumina present, the wool absorbs acid as well as alumina, and the shades on dyeing will be deficient in colour and fastness. If there is too little alumina the colours will be loose to rubbing. The baths must be absolutely free from iron or copper. Iron is a common impurity of alumina salts. Work the wool in the bath—cold—for about 15 minutes. Then boil up and boil about one hour or rather less. Then dye. When iron is used, the bath is made with 3 per cent. to 5 per cent. of ferrous sulphate, and 2 per cent. to 3 per cent. of tartar, or 1 per cent. to 1½ per cent. oxalic acid.

In dyeing wool with some colours, for instance, alizarine WS, the process is different. A bath is made with 10 per cent. of Glauber's salt and the dye. After the wool has been boiled in this for half an hour it is lifted, and 4 per cent. of sulphuric acid is added to the bath. The wool is re-entered and boiled for another half an hour. Then the iron, chrome, or alumina mordant is added, and after 45 minutes' more boiling the process is finished.

Mordant colours are too expensive for silk, as a rule, but, when used, alumina is the chief mordant, as silk is difficult to mordant with chromium.

Besides alizarines, this class includes some of the anthracenes, such as anthracene brown, flavopurpurine, chrome fast yellow, galloflavine, diamond blacks, gallamine blue, and chromo-cyanine.

Insoluble Colours. The insoluble colours can be divided into two classes—those which are added to the dye-bath in the usual way, but must be reduced, like indigo, or require a special solvent other than water to dissolve them, and those which are produced on the fibre. It might at first seem that the mordant dyes ought to fall into this second class, but, although the actual colour produced is undoubtedly affected to some extent by the nature of the particular mordant, yet in the case of the mordant colours a previously existing dye is employed, and the resulting shade depends mainly upon it, whereas in the case of the developed colours the dye is wholly manufactured on the fibre, so to speak.

The first class is represented by the sulphur dyes and the vat dyes, and the second, which may conveniently be styled that of the *developed colours*, may be divided into aniline black, paranitraniline red, and other diazotised colours.

Sulphur Colours. Canarin, discovered in 1821, might be ranked as the first of the sulphur colours, but it is an inorganic salt prepared by oxidising potassium sulphocyanide. The first of the organic sulphur colours (also called *sulphine* or *sulphide colours*) was Cachou de Laval, made in 1873 by fusing sodium sulphide with various organic bodies, such as bran and sawdust. It was followed much later by Vidal black (1893).

The great fastness of the sulphur colours is now bringing them rapidly to the front, although their use is at present almost confined to cotton dyeing. The dye is dissolved in sodium sulphide solution, and an average dye requires its own weight of sodium sulphide. Extra marks, however, require twice their weight, and the highly concentrated brands treble. Until quite recently these dyes have been put upon the market in a very impure state, so that enormous percentages of them were

required, but this state of things is now much improved. Some of the very concentrated marks give full shades with 5 per cent., or even 4 per cent.

The bath must be made with Glauber's salt and also carbonate of soda (soda-ash) to increase the affinity between the dye and the cotton. Various special precautions have to be taken. Wood only must be used for the dye vat. The goods, although entered at the boil, should not be allowed to boil in the bath. Steam should be shut off as soon as the goods are in. During the dyeing the goods must be kept immersed, as contact with the dye and with the oxygen of the air tenders the fibre, and at the same time tends to make it assume a bronze appearance.

As regards the quantity of sulphide of sodium to be used, the best rule is to put just enough to dissolve the dye. The colour will come out very thin if any notable excess of the sulphide is used. The bath is kept standing, and reinforced with dye and sulphide as may be required. The dyed goods are centrifuged, rinsed, and fixed with bichromate and sulphuric acid, with sulphate of copper or peroxide of hydrogen, or by steaming. Overaction of the fixing agent must be avoided, as it tends to weaken the material. In all cases the goods are rinsed free from fixing agent and then soaped to neutralise any excess of acid, and also to take away the harsh feel left in the fibre by the dyeing. When the soap has been rinsed out nothing remains but to dry the goods.

Sulphur Dye-baths. A very essential precaution in dyeing with the sulphur dyes is to use baths as short as convenient. While the average cotton-dyeing bath has twenty times the weight of the goods, it should be restricted to about twelve times the weight in the case of the sulphur dyes. In some cases a simple air oxidation suffices to fix the colour, so that the dye can be used like indigo. Such dyes are much preferred, and naturally so, as not only does the fixing in other ways cost time and money, but almost always alters the shade, thereby making it difficult to dye to pattern. There are already more than 200 brands of sulphur dyes now upon the market, and the range is daily increasing. To begin with, black was the only colour producible with the sulphur dyes, but the makers gradually added grey, brown, olive, blue, yellow, red, and violet. The range of shade producible with sulphur colours is now almost complete.

The chemical constitution of the sulphur dyes is not accurately known—*i.e.*, the correct formula cannot be stated. In 1906, however, a very remarkable dyestuff was put on the market under the name of thio-indigo-red B, which had a distinct chemical formula and may be regarded as an artificial indigo in which the two imido groups are each replaced by an atom of sulphur. It therefore has the relationship with indigo on the one hand, and with sulphur colours on the other. Thus it may be reduced, like indigo, in the vat, or dissolved in sodium sulphide solution like a sulphur colour. The range of pink to red shades that it gives has notably assisted to complete the series of sulphur dyes. The dye combines well with indigo, with the other sulphur colours, and with basics, thus giving a range of shades with remarkable qualities of fastness.

Vat Dyes. By "vat dyeing" is understood a process in which a matter insoluble in water is reduced to its leuco—*i.e.*, colourless—base in the dye-bath, and is reproduced upon the fibre by oxidation. Thio-indigo-scarlet quickly followed thio-indigo-red, the remarkable dyestuff described in the preceding paragraph, and in this only one of the imido groups is replaced by sulphur. It is used in the hydro-sulphite vat, and was quickly followed by a highly important group of vat colours used in the same way, the fermentation vat employed for indigo being less suitable and much more difficult to manage. In addition to many brands of artificial indigo these vat dyes now include a perfect gamut of tint and colour. The most important are the ciba, hydron, helindone, and indanthrene colours.

Vat dyeings on cotton are fast to alkali, washing, light, and chlorine. Among the fastest are the carbazol group. Hydron blue of this group can compete with natural indigo when dyed on cotton.

The vat dyes are also very important in linen dyeing, as they give the fibre very fast colours at temperatures low enough to prevent tendering.

On wool the dyeings of suitable vat colours are as fast as on cotton, and the wool is not in the least damaged by the dyeing process. Loose wool or slubbing is much easier to spin than when dyed with any other class of dye.

The only fault of the vat dyes is their high cost. This is compensated for, however, by the manner of use, as they are chiefly employed for embroidery, or for the warp threads of shirtings dyed in light shades. For these purposes they have the advantage of being extremely fast to washing. They may go to the laundry again and again without even showing any change of colour, and they will even withstand a mild bleach.

Azo Colours. In 1880 Read Holliday & Sons, of Huddersfield, patented a process for forming azo colours direct on the cotton fibre. The soluble azo colours are not cotton dyes, as no mordant has been found to fix them on this fibre, but Messrs. Holliday showed that they could be *made* on the fibre. The principle of the process of producing an azo dye is this. An amine, such as naphthylamine, is taken, dissolved in hydrochloric acid, and then diazotised by treatment with sodium nitrate; the diazo compound so produced is then combined with a phenol or an amine, and a colour is produced. This may then be treated with sulphuric acid, and thus converted from an insoluble to a soluble form. Messrs. Holliday, in their process, caused the cotton fibre to be impregnated with a solution of the amine; the fibre is then passed through an acid bath of sodium nitrate, whereby the diazo compound of the amine is produced on the fibre, which is now passed into another bath containing an amine, or phenol, or some other body capable of combining with the diazotised amine to form a colour—what this will be depends upon the amine that has been used.

At the time little use was made of the discovery, and attention was urged to it once again when another English chemist created a sensation in the dyeing world.

Primuline, already mentioned as a direct cotton colour, dyes unmordanted cotton a primrose yellow. Mr. A. G. Green made the remarkable discovery, in 1887, that by diazotising primuline on the fibre with nitrous acid, followed by a treatment with a phenol or an amine, a range of very fast and beautiful colours was produced, varying with the developer used, for instance:

Beta-naphthol	gave red.
Beta-naphthol-di-sulphonic acid R	,, maroon.
Resorcinol	,, orange.
Phenol	,, yellow.
Meta-phenylene-diamine	,, brown.

As these were produced in the fibre they were called "ingrain" colours, and the Germans call this class "ice colours," as a very low temperature is necessary for the diazotising bath.

As already mentioned, some direct dyes are advantageously diazotised and developed in this way, notably many of the diamines. This process increases the intensity of the dyeings or effects a change of shade. In either case the dyeings are improved in fastness to washing, and frequently also in fastness to light and cross dyeing.

An analagous process is known as "coupling." Diamine colours, for instance, may be coupled on the fibre with nitrazol or paranitraniline, with a resultant increase of fastness to washing and milling, and in some cases the resistance to light and cross dyeing is also improved. The cold coupling bath is charged with a solution of nitrazol or diazotised paranitraniline, soda and acetate of soda, and the dyed and rinsed cotton is treated in it for a period of half an hour.

Insoluble Azo Dyes. As regards the insoluble azo dyes, however, the number in use is very limited, but at least one, paranitraniline red, familiarly known as *para red* in the dyehouse, is highly important. It is produced by steeping the goods in a solution of beta-naphtholate of soda—that is, a solution of beta-nephthol in caustic soda, usually with the addition of Turkey-red oil—drying and developing at once. The developing bath is made by dissolving paranitraniline in a hot solution of hydrochloric acid. Cold water is added, and when the bath is quite cold nitrate of soda is added. Naphthylamine claret is the next most important insoluble azo colour. It is prepared by diazotising alpha-naphthylamine. Effective means of discharging it on the fibre to produce white and coloured patterns have been discovered. Dianisidine blue is obtained by developing dianisidine with beta-naphthol.

Toluidine orange, amido-azo-toluol garnet, and a few other insoluble azos have found limited uses and are produced in a similar way.

Aniline Blacks. Aniline black is generally divided into two classes—oxidation blacks and steam blacks. The formation of aniline blacks depends upon the oxidation of aniline. Its use is practically confined to cotton, because wool and silk, having reducing properties, seem to prevent the oxidation of the aniline. It is possible, by a previous treatment of the animal fibre, to remove the difficulty, so that afterwards the aniline black can be applied by the same processes as for cotton. The most successful process is to fix Prussian blue on the wool or silk, alone or in mixture cloths, then dyeing with any aniline black.

Cotton is dyed in various ways with aniline black. When the oxidation is effected by a liquid the black is called an "oxidation black." When, however, it is effected by air aided by steam, the black is a "steam black."

Oxidation Black. The following is a method of preparing an oxidation black: Make the bath with 40 per cent. hydrochloric acid (34° Tw.), 10 per cent. aniline oil, and from 10 per cent. to 14 per cent. bichromate of potash. The bath should weigh about sixteen times as much as the cotton. The aniline is dissolved in the acid and the bichromate in water first. The aniline is first added to the rest of the water, and then the bichromate. The cotton is worked cold in the liquid for an hour. When the colour of the cotton is fairly strong, heat up the bath slowly to 140° F. to 150° F. At least three hours should be occupied in the dyeing, as the slower the process is the less chance there is of the black turning green on exposure to the air. On lifting the cotton it is well rinsed, soaped, and rinsed again.

Steam Black. Dissolve separately 6 per cent. aniline oil, 9 per cent. hydrochloric acid, and 12 per cent. sulphuric acid in 200 per cent. of water. Dissolve separately 12 per cent. of sodium bichromate in 200 per cent. of water, and mix the two solutions. Enter the cotton cold, and as soon as it is dyed, which takes two or three minutes, wring it, and steam for twenty minutes at 14 lb. pressure.

Prevention of Greening. Cotton dyed aniline black by either of these processes is usually given an oxidising bath of bichromate and sulphuric acid as a precaution against greening, but the black is sometimes topped with methyl violet with the view of concealing any greening that may actually happen. Sodium chlorate is also used as an oxidising agent in the production of aniline black, especially on piece goods, but it requires the assistance of other agents. Lightwood used chloride of copper as an oxygen carrier, and ferrocyanide of potassium has also been employed. Probably the best yet known is ammonium vanadate or vanadium chloride.

The cotton is impregnated, for example, with 5 per cent. to 20 per cent. of hydrochloride of aniline, 2 per cent. to 10 per cent. of chlorate of potash, and a very small quantity of the vanadium salt (about three-thousandths of the weight of the aniline salt). The black is developed by oxidation in a current of air kept damp by steam, and passing over the cotton at a temperature of about 80° F. A much better and quicker development is obtained by the use of the Mather & Platt, in which the goods are passed through hot steam in a closed chamber. The temperature used depends upon the kind of black in question, being about 200° F. for ferrocyanide black, but for Lauth's sulphide of copper black about 160° F. only.

Artificial Indigo. The artificial synthesis of indigo is of decidedly earlier date than the putting of the product upon the market, but for a long time the cost of its manufacture prevented it from competing with the natural dye. In 1870 Baeyer and Emmerling made it from coal-tar products until 1878. In 1880 Baeyer prepared indigo from cinnamic acid, and in 1882 Baeyer and Drewson prepared it from orthonitro-benzaldehyde by the joint action of acetone and caustic soda. This artificial indigo was put on the market in 1893, in combination with hydrosodic sulphide, under the name of indigo salt, by Kalle & Co. Another synthesis of indigo, from phenyl-glycocoll, by Heumann, was published in 1890. The process belongs to the Badische Anilin und Soda Fabrik, and forms the basis of the method by which that company now prepares its indigo rein (indigo pure), which was put on the market in 1897. All these artificial indigos are identical with one another, and with the indigotin of the natural dyestuff.

Operations Preliminary to Dyeing. Even if goods are to be dyed in the grey state they must pass through a preliminary treatment before they can be properly dyed. They have gathered grease and dirt in the process of spinning and weaving, and the wool has been purposely oiled, and the cotton warps have been stiffened with size, which will act as a resist to the dye. The goods, therefore, must be bleached, or thoroughly scoured, or wetted out.

In these and in the dyeing processes the quality of the water used is of the first importance. A vast volume of it is required in the dye-houses, and an abundant supply of pure water is a prime necessity.

The subject of softening and purifying water has been treated on pages 3430 and 5451. Here it is sufficient to say that the dyer requires "soft" water, and even a trace of iron in it would be fatal to his operations. As the preliminary operations and, in particular, bleaching vary with the different fibres, we must consider them under the headings: Cotton, Wool, and Silk.

Wetting Out Cotton. The grease and dirt is removed in this operation with a mild alkali, and the fibre is uniformly impregnated with water in order to allow the dye to penetrate it evenly. Air-bubbles in the fibre are quite sufficient to cause uneven dyeing, and these are removed in wetting out. The usual method is to boil the goods with water containing 2 lb. or 3 lb. of soda-ash per 100 lb. of goods. The addition of a pure, well-made soap assists the operation. In some cases the wetting out is done in the machine used in dyeing. For instance, raw cotton, and sometimes hanks and warps, are treated with boiling water for half an hour, or more, in the machine before the dye-bath is made up, and piece goods are given a few ends through boiling water on the jigger. More frequently a boiling-box or low-pressure kier is used. Sometimes water alone is used—for instance, in cases where the dyestuff to be used would be affected by the soda—and in some cases it is advantageous to substitute a smaller proportion of caustic soda. This is quite sufficient preliminary treatment, as a rule, for dark shades.

Bleaching Cotton. The most perfect bleach is naturally needed by the calico printer, and in some cases, even for light shades, the dyer is content with steeping the goods already wetted out in a weak bath of bleaching powder, without heat, for a few hours, washing, souring with dilute hydrochloric acid, and washing thoroughly.

Bleaching is discussed in the course on TEXTILES, to which the reader is referred [see page 3259]. It is sufficient to remark that the dyer and calico printer is frequently satisfied with a less perfect bleach than when the goods are to be put on the market as "whites."

Singeing. This is a step of the bleaching process, especially when the cloth is to be printed, but frequently it is advisable to singe goods to be dyed in the grey, and it is a necessary process in lustre mercerisation and schreinerising. When yarn has to be singed, as, for instance, in the case of fine counts that are to be given the appearance of silk, either by mercerisation or by a mechanical process, this is a work of the spinner, who "gasses" the yarn—that is, passes it at a high speed several times through the flame of a Bunsen burner. Many forms of machines are used for cloth, and the singeing is done by coal, coke, or gas, and even electricity has been tried. Sometimes the cloth is passed over a hot plate heated by fuel, and at one time the difficulties in the way of employing the direct flame of the gas for cloth singeing made the plate machine the principal one used for the purpose.

Wool. Wool "in the grease"—that is to say, as it is obtained from the sheep's back—in addition to dirt, contains a heavy percentage of fatty bodies insoluble in water, called "suint," consisting principally of potassium salts of organic acids. As these are removed before spinning, however, this is not the dyer's business, and is treated in TEXTILES [see page 2213]. The woollen spinner, however, is obliged to oil the wool in spinning to give it suppleness, and, whether from the yarn or cloth, this must be completely removed before dyeing or bleaching. This is a simple enough operation if good olive oil has been used, but much trouble in the dye-house has resulted from the use of mineral oils, which are unsaponifiable.

Scouring. The yarn is scoured in a solution of soap alone, or of soda and soap, but the bath is not heated above 110° F. It is frequently done by hand, the hanks being hung on sticks as in dyeing, worked in the same way. When sufficiently scoured the yarn is washed thoroughly, squeezed, and dried. Cloth is not always scoured before dyeing when it is to be dyed black, but for the best work it is always necessary. A very ordinary form of machine is the "dolly." This practically consists of a pair of squeezing rollers revolving over a tank containing the bath of soap and soda. The pieces are sewn together in a continuous band, and passed in rope form—that is to say, not opened out—through the bath by means of guide rollers, and through the nip of the squeezing rollers. The scouring is continued until the pieces are perfectly clean. Setting, crabbing, and bleaching, all necessary preliminaries to dyeing, are described in the course on TEXTILES.

Silk. The object of the preliminary operations in this case is not only to prepare the material for dyeing, but also to make it soft and lustrous. This is done by removing more or less of the silk glue, and, according to the degree to which this operation is carried, the material is called "boiled-off silk," "souple silk," or "écru."

Boiling Off. The silk is worked for an hour rather under the boil in a bath made with about 30 per cent. of soap. The gummy, soapy liquor that results is known as "boiled-off liquor," and is used in the silk dye-bath. The silk is then washed in water in which a little soda-ash is dissolved, and scoured. For this process the silk is put into hempen "pockets" and boiled, sometimes as long as three hours, in a soap solution about half the strength of the previous bath. It is then washed thoroughly in soft water, and dried.

Soupling. The raw silk is first scoured by working for about an hour in a lukewarm bath made with about 10 per cent. of soap and a little soda. It is then worked in a solution of aqua regia in a stone trough, bleached after the manner of wool by sulphuring, and, without removing the sulphur, is softened by working in a solution of cream of tartar at about the boil, or a little under. The process requires experience, and should be studied in works like Hurst's "Silk Dyeing."

Ecru Silk. This is simply scoured in a lukewarm bath of soap and soda. This removes the fats, but very little of the gum. In this state it may be dyed black, but for other colours it is bleached.

Bleaching. Silk can be sulphured in the same manner as wool, but the white obtained is very fugitive. The best agent is peroxide of hydrogen or perborate of soda. The scoured silk is simply treated in an alkaline bath of peroxide. It is entered cold, left for twelve hours, and then the bath is made lukewarm, and the process is finished in another three hours. This is slow, but an unhastened cold bath is better in peroxide bleaching, whether for wool or silk.

ARTHUR MORRIS

The Railway Clearing House and Its Work. Science in Modern Railway Work. Legal and Sundry Departments.

MINOR RAILWAY DEPARTMENTS

UNTIL the year 1842 the working of through traffic—that is, traffic originating on one line and passing over one or more continuous but separate line or lines—was cumbrous and vexatious, each company collecting its own tolls and keeping its own accounts. In that year Mr. Kenneth Morison propounded and successfully inaugurated his clearing system, by which the foreign or through traffic of the companies is accounted for by the terminal companies interested to the Clearing House, the companies receiving their relative proportions through that channel.

The Railway Clearing House. The Clearing House performs a kind of work which could not have been performed by the companies, no matter how amicably disposed towards each other they might have been. It maintains perfect accord among all manner of conflicting interests. Once a party to the Clearing House system, a company knows it must abide by its decisions. However, any company may withdraw at will by giving one month's notice under seal, or a company may be expelled by the votes of two-thirds of the delegates present at a meeting specially convened for the purpose.

The travelling public seldom realise how much they owe to the clearing system, for by means of this institution they, both as freighters and passengers, are saved much trouble and annoyance. For example, a passenger can book for a journey, say, from Penzance to Wick, and one little piece of pasteboard franks him over several separate and absolutely distinct railway properties. Without the system he would be burdened with a book of coupons, to vouch him over each railway in turn, or might even be compelled to take a fresh ticket at every junction of the different companies' lines.

The Growth of the Clearing House. Like most great institutions, the Railway Clearing House had a very humble beginning, for, writes Sir John Findlay, "it began its operations with a staff of only four clerks, and dealt with the traffic of only four railways, controlling an aggregate mileage of 418 miles; but its growth has only been paralleled by the growth of the railway system itself." Every railway of importance is now a party to the Clearing House, the clerical staff of which numbers upwards of 2500, while there are, in addition, some 500 "number-takers" employed up and down the country, whose business it is to examine and report upon the vehicles of trains passing through important junctions. The original home of the Clearing House was a small house in Drummond Street, near Euston Station, but before many years had elapsed its operations attained such magnitude that a move was made to its present home, the huge building in Seymour Street, N.W. England and Scotland are represented in the institution in Seymour Street, while Irish business is transacted in the same form at the Irish Railway Clearing House in Kildare Street, Dublin, which was established in 1848. The work of the Railway Clearing House is divided into departments, of which the three largest and most important are as follows: the Merchandise, the Coaching, and the Mileage Departments.

The Work of the Merchandise Department. The Merchandise Department is charged with the apportionment month by month of the receipts derived from the carriage of all "through" goods, cattle, coal, and mineral traffic. The department is supplied every month with returns from all stations, giving full particulars of all such traffic. Every station sends in two distinct forms, one concerning the "outwards," or forwarded traffic, which is printed in black, and the other relating to the "inwards," or received traffic, printed in red. These abstracts state the character of the goods, their weight, the rate per ton, the charge, and whether it is "paid" or "to pay," the number of the waggon in which the consignment travels, and the name of the owner of the waggon. The two abstracts are carefully compared, and steps taken to rectify errors or discrepancies between them.

The monthly settlement is arrived at as follows: first, all total receipts between a pair of stations which amount to less than £1 are thrown out and credited to the "light traffic fund." Next, taking the remaining receipts from the traffic which has passed between each pair of stations, the terminal allowances, fixed tolls, and amounts "paid on"—that is, disbursed by the forwarding company for any special service rendered—are deducted. Thirdly, the residue is divided by mileage between the different companies concerned, so that each company gets a due proportion according to the distance it has carried the traffic. Lastly, to obviate a plethora of small accounts, the amounts credited to the "light traffic fund" are divided among the different companies in the ratio of their gross receipts from the heavier traffic.

"Clearing" the Coaching Traffic. The Coaching Department is charged with the division of receipts on all "through" traffic by passenger train—namely, passengers and their luggage, horses, carriages, dogs, parcels, fresh fish, perishables, and the like.

The passenger traffic is dealt with monthly. The booking clerks render every month to the Clearing House a return specifying the through tickets issued, and every stationmaster has to forward to the Clearing House all tickets collected at his station during the month and issued by any company other than his own, save that the tickets in which two companies alone are interested are not checked by the Clearing House unless they are issued and collected by the same company.

The receipts derived from "through" tickets are divided by mileage, but no company may receive out of a through rate more than its local fare, which means that some companies' mileage proportions have to be reduced to their local fares, and the balance divided among other companies whose proportions do not come up to the amount of their local fares. The remaining items in the coaching traffic are settled half-yearly, and here, again, occurs a light traffic fund, this time limited to 5s. On the

parcels, fish, and perishable traffic, terminal charges have to be taken into consideration, whereas no terminal charge is levied on horses, dogs, and carriages. Here it may be noted that it was only by the assistance of the Railway Clearing House that the Post Office was able to establish the Parcels Post under the Act of 1882. The great difficulty that attends this phase of the Clearing House settlement lies in tracing the route by which parcels, etc., have travelled. Theoretically, the way-bills that ought to accompany all parcels, and which are supposed to be stamped at each junction, should explain matters, but parcels and way-bills are apt to get separated, and the stamping of way-bills is frequently omitted.

The Mileage Department and its "Number-takers." The Mileage Department keeps the mileage accounts of the various companies in the matter of rolling stock of one company passing on to the territory of another, and attends to the question of demurrage for detention of carriages, waggons, and tarpaulin sheets.

The staff of "number-takers," whose members are found at every junction of two railways, records the number and description of every vehicle and sheet that passes a junction going from one line to another. In addition, every station receiving foreign stock makes a similar return, which shows how the latter got there and what was done with it. Each company's stock is shown separately under three headings—Carriages, Waggons, and Sheets.

Demurrage Regulations. Revised demurrage regulations by the railway companies of England and Wales were put into operation on January 1, 1913, as follows: Before conveyance, 1s. 6d. per ordinary waggon per day, and 3d. per sheet per day after the expiration of one day, exclusive of the day on which the loading of the waggon is begun. After conveyance, 1s. 6d. per ordinary waggon per day, and 3d. per sheet per day after the expiration of two days, exclusive of the day of arrival. Waggons of special construction or of large capacity are subject to special arrangements.

The Scottish regulations include waggons used for coal and coke traffic, which are specifically excluded from the notice given by the English and Welsh companies, on whose lines coal traffic is almost wholly carried in private owners' waggons, whereas the Scotch railways carry coal as well as other kinds of traffic in their own waggons. The companies also gave notice of their intention rigidly to enforce demurrage charges, which hitherto had been rarely done. The demurrage on coaching stock is 10s. per first-class carriage per day, and 6s. per third, second, or composite class carriage per day.

Clearing House Conferences. These are usually held every three months, and comprise the following: Goods managers, to discuss classification of goods rates, mileage charges for the use of waggons, construction of private owners' waggons, and similar matters; superintendents, to deal with the speed and signalling of traffic, rules and regulations relating to the safe working of the lines, excursion facilities; general managers, to review the recommendations of the former conferences, and then to frame proposals to be submitted to the committee of delegates for their adoption.

Organisation and Staff. The Clearing House business is regulated by a chairman, elected annually, and by committees of the traffic officers of the various companies—the general managers, goods managers, and superintendents—who sit once a quarter at the Clearing House premises. The two last classes of officers sit in the same week on separate days, and the former a few weeks later, to revise and approve the minutes of proceedings.

The working expenses of this vast and admirably managed organisation, which makes no profit and incurs no bad debts, are borne by the companies in the ratio of the business done on their behalf.

To obtain a junior or apprentice clerkship in the Railway Clearing House, application must be made to the secretary, and approved candidates have to pass an ordinary clerkship examination. The Clearing House "number-takers" join the service as lads, after they have been medically examined as to sight and physical soundness. Lad "number-takers" are posted to one or other of the junctions where waggon numbers are recorded, and begin to learn their duties by making out returns. Subsequently they are put to work in the yards under older hands.

The Chemist and the Railway. The chemist has always filled an important rôle in the locomotive department of a railway; and when it is considered that this department—with which, as a rule, is incorporated the carriage and waggon department—forms the great spending arm of a railway company, it becomes easy to understand how he should be the man to whom the locomotive engineer looks to point the way towards effecting economies. Every day the scientific side of the railway profession is coming more to the front, since an increasing number of solutions of questions capable of definite scientific treatment is constantly being discovered. Thus there are more and better openings for railway chemists, while the field of employment is no longer confined to a locomotive department laboratory, but also embraces that of a general engineering chemical laboratory. The two laboratories are, however, kept distinct, for although many of the chemical and physical investigations which are performed therein cover the same ground, the object in each case is different, necessitating a different kind of analysis. For example, there is the scrutiny of water. In the locomotive laboratory the chemist is concerned only with the quality of the water for feeding boilers. He has to examine it in order to see that it does not contain an undue proportion of chalky matter, which would deposit scale upon the tubes and firebox plates, and so impair their efficiency as conductors of heat from the furnace to the water. Again, he analyses it to see that it does not contain any corrosive salts, such as magnesium chloride, which would cause the structure of the boiler itself to be corroded.

Scope of the Engineering and Locomotive Laboratories. In the engineers' laboratory the chemist has to concentrate his attention upon the suitability of the water supply for domestic purposes. A railway company owns hundreds of cottages and houses up and down the line for housing its employees, and all these dwellings must, of course, be supplied with a pure water supply, suitable for both human consumption and domestic purposes. And the same rule holds good in the case of stations.

The examination of the different kinds of oil for the lubrication of the locomotive is a most important feature of the locomotive chemist's duty; and the other sorts of oil which are employed in the paint-shop for mixing the paints and varnishes used to protect and decorate the outer surface of engines and rolling stock likewise demand

his attention. The engineers' chemist also deals with oils—those for the paints used to cover all woodwork. Then photometric work is common to both establishments. The locomotive chemist tests the oil for the signal lamps, together with the gas-burners and incandescent mantles for the lighting of the carriages, while the engineers' chemist investigates the qualities of every means of illuminating stations and offices. The efficient lighting of station premises is a subject in which advertisers have a direct interest.

Things which concern the locomotive chemist alone are the steel analysis and metallurgical work generally, in the case of those railway companies which have their own steel-works ; the analysis of pig iron, coke, and various other materials for the iron foundry ; the analysis of copper-plate for fireboxes, copper tubes for the locomotive boiler, and bronze bars for firebox stays ; the analysis of the materials for bearing brasses and bronzes, and the examination by combustion in a calorimeter of the coal by means of which water is to be converted into steam to propel the trains. The coal for the locomotives must not contain much fusible ash, otherwise it is liable to choke the fuse-ends in the firebox and prevent the boiler from steaming properly. The composition and quality of its ash, together with its heat-giving qualities, can be determined only by an exhaustive calorimetric test.

The engineers' chemist has his own peculiar field in analysing the creosote for sleepers and the cement for buildings, while some companies ask him to conduct the most searching investigation in regard to broken rails.

The Inquest on Fractured Rails. The London and North-Western is the only railway that rolls its own rails. The plant at Crewe has a capacity for turning out 45,000 tons of rails annually, the mill being driven by a 700-horse power engine. In the purchase of rails from private manufacturers, a company's inspector has the lot laid out on a bank, in order to scrutinise each rail. Quite 30 per cent. are rejected or sent back to be straightened ; but, of course, the inspector cannot detect inherent flaws. To ascertain the cause of the latter, the following procedure is adopted. The fractured rail is sent to the engineers' laboratory, accompanied by a report from the district engineer, stating the date when discovered (a ganger finding a broken rail is suitably rewarded), and the locality ; whether the rail belongs to an " up," " down," or a single line ; particulars of the fracture, accompanied by drawings ; the distance of the fracture from the nearest bearings on each side, and the distance from the nearest joint ; if in the double line ; whether on the leading or trailing side of the nearest side ; if the rail was on curve, the radius of the curve, and whether on the inside or outside of the curve ; the period the rail had been in use ; the average number of trains passing over it per day ; the section ; the weight per yard when new, the actual weight per yard at date of fracture ; the loss of weight per yard, and whether the rail had been turned or not. The chemist cuts two slices as near as possible to the fracture, and if it is a long split the slices come right across it. One slice he polishes, and then etches with 20 per cent. of sulphuric acid for two hours at 60° C. The slice is next photographed, and from its appearance he selects portions of the other slice for microscopic examination, taking a piece from the centre of the head, a piece from the web, a piece from the side of the head, and a piece from near the running edge. These pieces are polished, etched with sulphuric acid, and photographed under the microscope. The rail is also analysed chemically, drillings for analysis being taken either from close to the fracture or from one or other of the slices. Finally, a detailed report, illustrated with microscopic photographs, is forwarded to the chief engineer.

The Evils of Hard Water. There is now no feature of locomotive operation and construction which constitutes so great a problem as the maintenance of boilers, and this is intimately associated with and affected by the character of the feed water. When hard water is evaporated in a boiler, the incrusting impurities are deposited inside the boiler, or on the boiler tubes in the form of scale. The accumulation of this scale not only increases the cost of fuel, but, by placing insulation between the boiler and the water, allows the sheets and flues to become overheated, subjecting them to extremes of expansion and contraction. Then, too, it is necessary to shut down the boiler once or twice a week to remove the scale by " washing out," which operation is referred to in the section dealing with the work of the enginemen. Again, corrosive salts, such as magnesium chloride, in hard water cause the structure of the boiler itself to corrode, thus shortening its life.

Water-softening for Railway Purposes. Of necessity, railways have located their watering stations where there is an abundance of water, without regard to its quality. More recently, however, the keen competition of new industrial conditions has led progressive managers to appreciate the immense saving that can be effected by having a soft water for use in boilers. To secure the best and most economical results from water to be transformed into steam, it must be softened —that is, freed from scale-forming impurities. Considerable attention has been lately devoted to the subject, and different systems of water softening are now being adopted. Many large plants have already been established at important locomotive centres in this country—notably, on the North London Railway, outside Broad Street Station, where it is stated that no less than 70 tons of deposit are collected annually ; on the Great Western Railway, at Goring, where the water for the track troughs is pumped from the adjacent river, and at Aldermaston, near Reading ; on the North-Eastern Railway, at Hessle, near Hull ; and on the Great Central Railway at Mexborough.

Water-softening Machines. In one quite common type of water-softening machine the water is mixed with the proper quantity of chemicals, common slaked lime and soda ash frequently being used, and the mixture is permitted to stand in large tanks by the side of the track until the solid hardening matter thrown out of the solution by the chemicals settles. The clear, softened water is then drawn off through a suction pipe attached to a float, and stored in a supply tank. After weeks of use it becomes necessary to remove the precipitated solid matter from the reservoirs, and this is accomplished by diluting it with hard water, and permitting the mixture to run off through a wastepipe in the bottom. The cost of operating the plant depends largely upon the amount of chemicals necessary, which in turn depends upon the character of the impurities in the water. Even where the water does not contain scale-forming or corrosive impurities, it has been found conducive to longevity and good work in a locomotive to subject the water to chemical treatment.

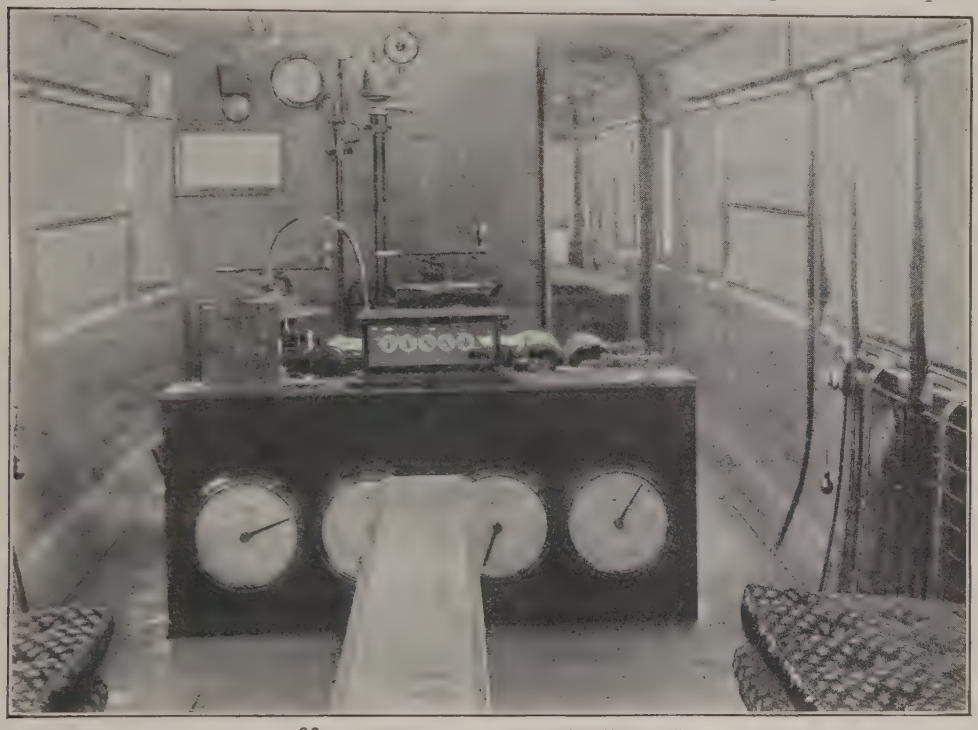
The Kennicott Water-softener. The Kennicott water-softening plant, which is in operation at Severn Tunnel Junction on the Great Western Railway, is capable of treating 30,000 gallons of water per hour. One man in half a day can give all the attention that is needed for a perfect operation of a softener with a capacity of 10,000 gallons per hour. The chemical reagents are hoisted automatically to the top of the machine, where are found the necessary receptacles for dissolving them, and the apparatus for automatically varying them in proportion to the quantity of water entering the apparatus. In the latest type the gear which proportions the chemicals does not come into contact with them. Only water is measured, and this measure and water proportions the chemicals. This represents a very important advance towards increased simplicity and accuracy. Surmounting the cylindrical steel tank is the water-wheel, over which the hard water is first pumped on its way into the softener.

The possibilities for economies that exist in the use of the water-softening system, such as we have described, for removing the scale-forming impurities from the boiler-feed water are almost beyond comprehension. The time for imperfect and incomplete methods, such as by using "boiler compounds" in any form, or by employing any treatment wherein the precipitation of the scale-forming solids is not accomplished, and the material removed from the water before the water is delivered to the motive tender, has passed.

Dynamometer Car Tests. In order to ascertain the tractive force exerted by a locomotive, several railway companies—namely, the London and North-Western, Great Western, and Lancashire and Yorkshire—employ a dynamometer car [90], which is a long saloon coach, replete with a number of complex and ingenious recording apparatus, which are described below.

The indicated horse-power of a steam locomotive signifies the work done in the cylinders or the maximum effort in propelling the locomotive itself and overcoming friction. But by means of a dynamometer car the engineer is informed what amount of power is available for hauling a given load, inasmuch as the actual work being accomplished by the locomotive is then indicated by the pull on the drawbar, coupled with the rate of speed. Thus valuable comparative data for testing the relative efficiency of locomotives are arrived at.

Dynamometer Apparatus. In the centre of the car is a specially constructed spring, free from friction. To this spring the drawbar of the car is attached, and in making a test the car is placed immediately behind the locomotive, where the stronger the force of the pull exerted by the locomotive the more the spring of the drawbar is deflected. The centre of the spring is coupled to a bracket, to which a sliding rod carrying a stylographic pen is attached. A similar pen is fastened to a small fixed bracket. When there is no pull on the drawbar, the two pens are in alignment, but when the locomotive is exerting a pull, the former pen is drawn away from the latter. The pens make contact with paper, after the manner of those fitted to self-recording barometers. The paper to furnish the impression of a chart rotates on drums, and so is wound across a table, according to one or other of two scales—namely, 1 ft. of paper to 1 mile on the line, or 2 ft. of paper to 1 mile on the line. An additional flangeless wheel, which can be raised or lowered at will so as to engage with the rail, drives the foregoing, together with all other



90. INTERIOR OF A DYNAMOMETER CAR

rotating machinery in the car. Accordingly, while a test is in progress, the paper is recording the impression of two inked lines. The line drawn by the pen attached to the fixed bracket is perfectly straight, and is known as the datum line, while that drawn by the pen in connection with the drawbar spring is wave-like. The constantly varying distance between these two parallel lines is measured with a special rule, which gives the force of the pull on the drawbar itself in tons and decimal parts of a ton.

It is next necessary to ascertain the rate of speed at which the tractive effort is being accomplished. This can be given approximately by a dial speed indicator, driven off one of the car axles; but to obtain accurate data the apparatus employed is a clock which is in electrical communication with an electromagnet to which another pen is attached. This pen is deflected, and makes serrations in the line that it draws across the paper every two seconds. Every tenth serration is shorter than the others, so that it can be easily identified. By measuring with a suitable scale the distance travelled by the paper between each tenth serration, the exact speed in miles per hour can be read off at once.

The registration on the chart of the locality of the test train is also very necessary. This is effected by means of an electric push connected with another pen. An operator takes up a position at a window, and manipulates the push according to a prearranged code. Thus, one push, which records one tick of the pen on the paper, signifies a quarter-mile post; two pushes, a mile post; three, a station; and four, a tunnel. Again, the working of the locomotive itself is recorded back to the dynamometer car by a similar push in electrical contact with another pen, this push, of course, being operated by an official on the footplate.

Testing the Work done by Locomotives. Another apparatus, known as an *integrator*, registers the work done by the locomotive in foot-pounds. By dividing the foot-pounds of work performed per minute by 33,000 (33,000 foot-pounds per minute are equivalent to one-horse power), the horse-power given out by the locomotive is at once obtained.

Dynamometer cars are also used for testing the efficiency of brakes. An electrical apparatus is connected up with the last or any coach of the train, and records the exact interval of time that elapses between the application of the brake and its taking effect on the wheels of the vehicle in question. Lastly, some dynamometer cars are equipped with an apparatus whereby the running stability of a coach is ascertained. In the coach to be tested is placed an instrument which may be described as a cast-iron spherical shell containing a cast-iron ball. Rubber tubes connect the shell with an extremely sensitive diaphragm in the dynamometer car, when every movement of the coach, as recorded by the oscillation of the ball within the sphere, is reflected by the impressions of a pen attached to the diaphragm.

Locomotive Stationary Testing Plant. However, even with the employment of a dynamometer car, the practical carrying out of a locomotive test under actual working conditions is beset with difficulties of various kinds, especially the practical impossibility of securing similar conditions on any two occasions. In order to obviate these disadvantages, a very elaborate and costly plant has been devised for testing locomotives in the shop. Very few specimens of this plant are in use, and the Great Western is as yet the only British railway to possess one. The latter is located at the Swindon works, where the employees have nicknamed it the "Home Trainer," in allusion to its functions being cast in the same lines as those of the machine of the name on which professional cyclists used to practise. The locomotive is run upon the machine, where its driving wheels rest upon rollers of about 4 ft. in diameter, which the rotation of the wheels causes to revolve, instead of propelling the engine. The axles upon which these rollers are mounted run in bearings which are capable of adjustment longitudinally, to suit the different wheel bases of the various classes of locomotives; and the smoke cowl, into which the funnel is inserted, is likewise adjustable. At one end of the machine is a traction dynamometer for measuring the drawbar pull, to which the engine is connected, while the load is put upon the locomotives by means of brakes, which are applied to pulleys upon the axles of the rollers. A locomotive is tested *minus* its tender, but the plant comprises a kind of dummy tender, over the traction dynamometer, from which the locomotive is fired, while the feed pipes are coupled up to a system of water supply, fitted with measuring apparatus.

Placed on the machine, a locomotive may be run at a constant load and speed for as long or short a time as may be desired. By measuring the speed, which can be ascertained by counting the revolutions of the wheels, and the pull exerted at the drawbar, the power given out by the locomotive can be determined at once. The measurement of coal, water, oil, and so on, is an easy matter; and, as a completely equipped laboratory forms part of the outfit, all manner of practical and exhaustive tests can be applied at the same time to a locomotive submitted for trial. On the Swindon machine, engines have been run at a speed of 70 miles per hour. Nothing of the energy which a locomotive exerts in propelling the road backwards, so to speak, is wasted, as the rollers are connected by driving bands to the shafting of an air-compressing installation.

Liquid Fuel for Locomotives. From the year 1886 until a few years ago, the Great Eastern Railway had a good many locomotives which burned a liquid fuel [91], composed of the waste tar from the compressed oil-gas utilised for lighting the coaching stock, on a system introduced by Mr. James Holden, the late locomotive superintendent of the company. The apparatus proved most successful, but, owing to the enormous increase in the demand for oil which has taken place of late years, leading to greatly enhanced prices for that commodity, the application of liquid fuel for steam boilers has ceased to progress on British railways, and has been discontinued on the Great Eastern itself. During the coal strike in 1912, several companies, but not including the Great Eastern, equipped a number of engines to burn liquid fuel while the strike lasted. The question of internal-combustion engines, employing oil, for railway purposes is quite another matter. It yet remains to be proved whether this machine can be made a practicable commercial success.

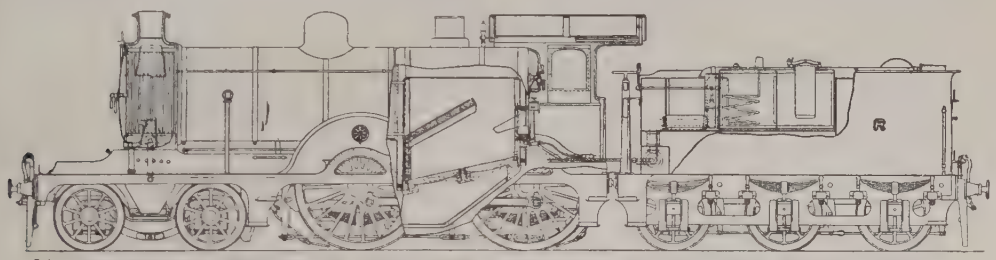
Necessity for a Legal Establishment. As railway companies owe their existence to, and conduct the whole of their business under, the provisions of several Acts of Parliament, it stands

to reason that they are bound down at every turn by legal restrictions and obligations, any transgression of which renders them liable to suffer pains and penalties. Accordingly, they have constantly to invoke legal assistance to define their rights and protect their interests. Most railway companies have special legal departments of their own, which conduct operations from headquarters. The directors appoint a duly qualified legal practitioner of high standing in the profession to take charge of the department, and provide him with a staff of duly qualified assistants, a managing clerk, and as many ordinary clerks and messengers as may be required. The salaried legal staff, of course, resign their general practices, and devote themselves entirely to the company's interests.

The smaller railway companies employ outside firms of solicitors, and at least one great English company does likewise.

The legal branch of a railway company is divided into departments. First, there is the department for Parliamentary work, which carries through Parliament the Bills promoted by the company for new lines and works

Conveyancing and Common Law. Secondly, there is the conveyancing department.



91. LONGITUDINAL SECTION OF LIQUID FUEL LOCOMOTIVE ON THE GREAT EASTERN RAILWAY

An enormous number of deeds pass through the hands of this office, which examines all titles with the greatest care. The number of title deeds, and the like, possessed by any railway company is so great that the general offices are equipped with a fireproof muniment-room for their safe custody.

Thirdly, there is the common law, or "writ and process" department, which covers wide ground. It deals with innumerable trifling matters in connection with claims, outstanding accounts, demurrage, rates and taxes, damage to luggage, animals, and crops; prosecutes fraudulent travellers, luggage thieves, and trespassers; defends actions brought against the company in connection with personal injuries to passengers; deals with cases of injuries to servants under the "Workmen's Compensation Act" of 1897; and is represented in the highest Courts, contesting some such celebrated suit as that of the Taff Vale Railway Company *versus* the Amalgamated Society of Railway Servants.

Qualifications of a Railway Solicitor. The ideal railway solicitor is essentially a railway officer possessing an intimate knowledge of the policy and aims of his company. He must be an experienced conveyancer, for enormous landed interests are entrusted to his keeping, and he must be thoroughly acquainted with Parliamentary procedure, together with procedure in the various courts of law and in arbitration cases.

The chief solicitor or his qualified assistants are at all times accessible to officers of every department who may wish advice in relation to their duties, while in all legal questions that crop up in the department the solicitor has to acknowledge the zealous assistance of officers of other departments.

The Railway Police Staff. Every railway company has its own detective and police staff, the uniformed members of which, as a rule, are far from being merely ornamental accessories of the company's service for the purpose of frightening evil-doers and possessing no power to act summarily in the event of detecting an offender. Under their Acts of Incorporation the railway companies were empowered to swear in so many policemen for each station, and some companies—the Great Northern, for example—have obtained later powers which sanction them to swear in as many of their staff as they think fit. The "sworn" men can arrest any person not only on the company's premises, but within 300 yards of the same.

The Railway "Scotland Yard." The officers of a railway company's detective and police department include a chief superintendent, a chief clerk, and a chief detective inspector, while the staff is composed of detective inspectors, detective sergeants, and uniformed constables. The companies favour recruiting for the department from *inside* the service. It is essential that even the constables should have some experience of the internal working of a railway, inasmuch as the general work of a railway constable differs considerably from that of his civil contemporary, for the former must always be a bit of a detective as well. As to railway detectives, an authority on railway management has laid it down that "a civil detective is of little use in a similar position on the line until he has acquired considerable experience of railway working." The majority of the men composing the "force," therefore, have been originally in the company's service in some other capacity, while the remainder may have been either selected candidates from the Metropolitan, City, or local police, or ordinary private individuals who applied for this kind of employment and were accepted as suitable.

The duties of railway detectives embrace a wide scope. There is the "shadowing" of persons suspected of making bogus claims on the company for personal injuries and loss of luggage. A most interesting volume could be compiled setting forth the cunning frauds which have been perpetrated, and attempted to be perpetrated, on railway companies on those grounds; then the most barefaced spurious claims for loss of luggage are constantly being detected, as, for example, the case of a woman whose alleged lost boxes were discovered to be held by her landlady for unpaid rent. The breaking up of thieving conspiracies hatched by the companies' servants themselves,

and the tracking down of well-dressed rascals who frequent the terminal stations for the purpose of snatching jewel-cases, dressing-bags, and other small articles which passengers have left unguarded in the carriages, keep the detective staff busily employed; but, when all is said and done, the detection of ticket frauds forms by far the larger proportion of their duties. Minor offences perpetrated against railway companies are stone-throwing at trains, trespass, and the malicious mutilation of carriage cushions, window straps and blinds. In all cases of loss or pilferage of luggage, parcels, or goods, the matter is at once referred to the railway police department, which is always in close touch with the civil police. Railway detectives are not, however, privileged to inspect prisoners awaiting trial. Therefore, the chiefs of the departments have a system of exchanging information in regard to the history of suspected persons in custody and of sending their own men to attend trials.

Free Luggage Allowance and Some Anomalies. A railway company is bound to carry free with each passenger his personal luggage to an amount fixed by the Acts of Incorporation of the several railway companies, according to the class of carriage in which the passenger travels. This amount varies in different Acts, but, in practice, the railway companies carry free 150 lb., 120 lb., and 100 lb. for first, second, and third class passengers respectively, and the company's liability with respect to passengers' luggage is the same as that with respect to goods entrusted to it for conveyance, so long as the passengers' luggage is under the charge of the company. If, however, the passenger takes the luggage under his own control, the company's liability is diminished, and arises only where negligence is shown on the part of its servants. The question of what constitutes *personal luggage* has been the subject of many judicial decisions; but, broadly speaking, personal luggage may be defined as consisting of such articles as the passenger requires for his own or personal convenience upon or in connection with his journey. Personal luggage does not include merchandise and materials, such as travellers' samples intended for trade purposes; neither are perambulators, sewing machines, bicycles, bath-chairs, children's mailcarts, hawkers' handcarts, harps, and street pianos admitted to be personal uggage. All this, of course, is fair enough, but it is not easy to see why certain small articles in every-day use, such as typewriting machines and phonographs, should be compelled to pay parcels rates.

The charges for excess luggage are not by any means strictly enforced by British railway companies taken as a whole; and at few stations is it a rule to weigh luggage before it is labelled.

The Baggage-checking Problem. Strictures are often passed upon British railway companies for their failure to adopt the American and Continental system of the registration of passengers' luggage, meaning that a passenger receives a voucher for his luggage at the departure stations and cannot claim any luggage at his destination station unless he produces that voucher. The registration system has much to recommend it on the score of being a prevention against the loss of luggage by theft or by passengers' mistakenly claiming what is not theirs, but it is wrong to suppose that its non-existence in this country is due to any lack of enterprise on the part of the railway companies. The truth is that the British railway traveller will have none of it, for he prefers running the risk of losing his luggage to incurring the slight delay which the system imposes upon him. In the past, the registration system was given a fair trial by several companies, who abandoned it only on the representations of the passengers themselves.

Luggage in Advance. Again, American visitors regard it as a backward state of affairs that the collection and delivery of passengers' luggage does not find widespread favour in this country. This, too, is due to the idiosyncrasies of British travellers, who prefer that their luggage should accompany them wherever they go, and have little faith in its being delivered by the company in time for their purposes. However, all companies now furnish facilities for the conveyance of passengers' personal luggage in advance—that is, collecting at hotel or residence in the principal towns, and forwarding in advance of the owner's journey, and delivery at hotel or residence in the town of destination, at a uniform charge of one shilling per package prepaid. Further, the luggage brought by passengers to any of the stations owned by some companies can be forwarded and delivered within the free cartage boundary at the owner's residence or hotel in the principal towns served by the despatching and also other railways, the charge being 6d. per package.

Lost Property and Left Luggage. The system of dealing with lost property and "left luggage" in a company's cloak-room is, as a rule, the charge of one special department as regards control of staff and general working, although the two transactions are conducted in distinct offices. The companies' servants are not allowed to take charge of luggage or other articles left at the station for the convenience of passengers.

The system observed in a cloak-room is to stack the articles in lots of "singles" (which are generally placed in racks), twos, threes, fours, and so on. This renders the work of identification easier when a traveller claims his property.

All unclaimed or lost luggage and other property found in the carriages at or on the platforms of the stations, or upon the line, must be immediately delivered to the person in charge of the station at or nearest to the place where the article has been found. At the expiration of three days all unclaimed or lost property is sent to the head-quarters of the company, where it is described and registered, and a copy of the register is sent to the Railway Clearing House daily. The Clearing House, in turn, furnishes the information to the different stations, and anything found on hand at a station which answers to the description of an article lost is sent up to the Clearing House for identification.

General Triviality of Unclaimed Articles. The extraordinary conglomeration of articles that find their way into the lost property office and are never claimed has inspired many writers with material for articles on the freaks of human forgetfulness. The machinery employed for tracing the rightful owners has now, however, attained such a pitch of perfection that the companies are burdened with a far less number of articles than formerly, while the articles themselves are mainly of a most humdrum and worthless description. No matter how small or worthless an article, it has a label attached, on which is inscribed the registered number that gives the clue to when, where, and in what circumstances it was found.

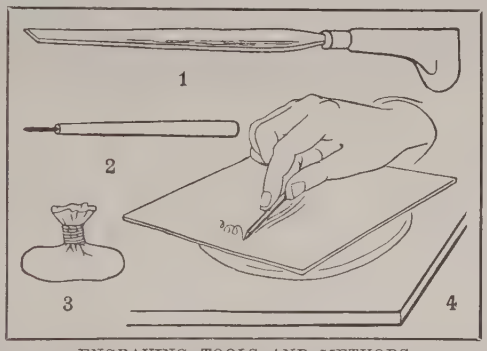
Copper-plate Etching and Dry-point. Etching in Tones. Line Engraving and its Masters., Prints in Colour. Engraving in Mezzotint and Wood.

THE ART OF THE ENGRAVER

An etching is a print taken by the method known as "copper-plate printing" direct from a metal plate on which lines have been bitten by an acid or other mordant. The plate may be of any metal; but iron, steel, zinc or copper have generally been used by artists; and the latter so greatly exceeds the others in suitability that it is almost invariably chosen. Zinc, however, has certain qualities of its own, producing a strong, rich line which is excellent for broad effects. Its treatment in no way differs from that required by copper, and the description of the process which follows applies to both metals.

Preparing the Plate. The plate used should be of good and even quality and its upper surface given a fine polish—circular. Such plates can be purchased ready for use. The polished surface must be overlaid with a ground, composed, as a rule, of beeswax, asphaltum, Burgundy pitch, and gum-mastic in varying proportions; but equal parts of each may be taken as a good formula for general use. The ground may be applied: (1) hot, by means of a dabber; (2) cold, as a paste dissolved in oil of lavender, by means of a roller; (3) as a solution in chloroform poured over the plate. The dabber [3] is made of horsehair, enclosed in cotton-wool, with an outside covering of silk or kid; and it is advisable to keep the stock of ground in a silk wrapper to prevent grit from getting into it. The grounded plate should next be smoked to a perfectly even blackness, by being clamped in a hand vice and moved to and fro over the flame of a bundle of wax tapers.



ENGRAVING TOOLS AND METHODS

1. Burin 2. Etching needle 3. Dabber for laying etching ground 4. Engraving on metal

The subject of an etching is drawn in line alone, the tool used being of steel, and called a needle [2]. This usually has a fine point and need not be otherwise, for though some etchers have employed a blunt tool for making broad lines, a better result is obtained by relying on the action of the acid for this purpose. The drawing may be made direct on the ground, in fine lines of uniform thickness, with pressure just sufficient to penetrate the ground but not to cut the copper; or, if desired, it may be transferred, either from a lead-pencil sketch made on thin paper, damped, laid upon the ground, and then passed through the press with a little less than ordinary printing pressure; or, again, it may be scratched upon gelatine with a needle, red chalk or some other pigment rubbed into the lines, and the transfer made in the press, as above, or by rubbing the back of the gelatine with a burnisher. In this case the gelatine should not be damped. When the drawing is finished, the back of the plate must be varnished with Brunswick black, to protect it against the action of the acid.

The Etching Bath. The drawing having been thus put upon the plate, the next step is that of subjecting it to the action of an acid bath which performs the function of etching—or eating out in the copper—the lines drawn with the needle. It need scarcely be pointed out that on the success of this delicate operation depends the whole merit of the final result, no matter how good may have been the original design. The bath is of porcelain, sufficiently large to enable the plate to lie conveniently within it, and shallow enough for the upper surface of the copper to be easily accessible. Various liquids—mordants—are used for biting-in at the discretion of the artist, who may, however, be advised to confine his attention at first to one only of the following, in order that he may become thoroughly well acquainted with its qualities and arrange the successive stages of the operation with certainty.

(1) *Nitric Bath.* Nitric acid, of specific gravity 1·42, and water in proportions varying from equal parts of each to ⅛ of acid and ⅞ of water, for copper. For zinc or steel much less acid should be used. Nitrous may be substituted for nitric acid.

(2) *Dutch Bath.* Hydrochloric acid, 10 parts; chlorate of potash, 2 parts; water, 88 parts.

(3) *Perchloride of Iron Bath.* A 40° Beaumé solution of perchloride of iron in water.

The plate is now immersed in the bath, and in the course of a few minutes the bright lines of the drawing will be seen to cloud over with minute bubbles of gas, produced by the action of the acid upon the metal. If the plate be removed from the bath, and the ground cleaned away with turpentine, it will be seen that every line drawn with the needle has been faintly eaten into the plate. If a proof be taken at this stage, the whole drawing will appear in fine lines such as are required for the lightest portion only of the print. Those portions which are destined to remain in this state must be covered again with ground. Stopping out, as this is called, is effected by a careful use of the dabber, leaving exposed all those parts which require strengthening. The plate is immersed again in the acid, and the whole operation repeated as often as necessary, until the proof shows a gradation, as nearly as possible perfect, from lines almost as fine as the needle-point itself to the deep

blackness which gives an etching its peculiar richness of effect. In the course of this proceeding it may be found that the whole design is too light.

Re-biting and Retouching. To darken the design "re-biting" is necessary. The dabber cannot conveniently be used, as it is difficult with it to keep the ground out of the already bitten lines. The difficulty is overcome in the following manner. Some ground is laid thinly and evenly on a piece of plate glass, and a roller alternately passed over this and over the plate, until the latter bears a sufficient ground. This should be done with the plates cold, until the operation is completed, when the oil of lavender can be driven off the copper by a gentle application of heat until the plate shines and the ground becomes hard. In carrying out this operation, the nature of the line made on the copper by the mordant must be borne in mind. This is not V-shaped, but, in section, somewhat wider at the base than on the surface of the plate, the edges being undercut to some extent by the acid. Advantage may be taken of this quality when the lines are over-bitten and print too dark; for, with a burnisher used with oil, their edges may be squeezed together and so made to hold less ink and print lighter. Additional work may, at any stage, be put on the plate with the needle, after re-grounding, and a local effect can be produced by applying the acid with a feather instead of placing the whole plate in the bath.

5. FROM A LINE ENGRAVING BY B. P. GIBBON, AFTER A. COOPER, R.A. (Working proof from unfinished plate)

Ink Distribution. The plate should now be ready for printing, which is done in a copper-plate printing-press, exerting such pressure as to drive the paper into every depression in the copper, and extract the ink therefrom. The ink used is made from any pigment with sufficient body, ground rather stiffly with burnt linseed oil; umbers or ochres being preferred for colour, and Frankfort black, heavy French black, or a lighter black, made from the smoke of burning paraffin oil, for the blacks. The two former are used for giving "body" to the ink, and the latter for blending to obtain special qualities of printing. A great deal depends on the printing of an etching. If the plate is cleaned as bright as possible, by means of the palm of the hand charged with ink and whiting, only the bare lines show, as in a visiting-card. But it is perfectly legitimate and very valuable to arrange the ink on the plate in such a manner as to get much richer effects. In such a case the ink is again worked with the palm of the hand, but with a gentler pressure so as to leave more of it on the plate outside the lines.

A further effect may be obtained by *retroussage*, the dragging of the ink into desired directions with a piece of soft muslin, which is lightly drawn over the heated plate along the lines, following the hand and bringing a portion of the ink over the edges of the lines. This process softens them and makes them print darker than would otherwise happen. By careful arrangement of the ink in these ways, a considerable amount of tone may be produced, but the process has to be repeated, necessarily, for each print. The plate must be kept warm over a "heater" in order to soften the ink, which is first applied thickly with a dabber; the surplus ink is then removed with a pad, and the final arrangement of it given with the palm of the hand as just stated. The paper should be of good quality—old hand-made rag paper is the best—and both soft and tough. It is used damp. At every stage of etching, the temperature must be taken into account. The student should study carefully the etchings of Rembrandt, Vandyck, Hollar, Méryon [7], Whistler (the "Thames Set" in particular), and Sir Francis Seymour Haden, P.R.E.

6. WINDSOR FROM ETON (From an aquatint by Paul Sandby, 1777)

In the soft-ground etching process, ordinary etching ground is used, mixed with half its weight of lard or tallow. The ground is laid and smoked, as already described. When cold, a sheet of thin paper is strained over it, and upon this the drawing is made with a lead-pencil, which causes the ground to adhere to the paper in a broken line, depending upon the grain of the paper, the hardness of the pencil, and the pressure used. The plate is then bitten and printed in the same manner as an ordinary etching, the result being a singularly faithful reproduction of a pencil line. Some good examples of this method can be seen in

A MEZZOTINT OF A HUNDRED YEARS AGO

THE GOLFERS—ENGRAVED BY VALENTINE GREEN FROM A PAINTING BY FRANCIS ABBOTT

FACING PAGE 5851

the work of Samuel Prout, but, at the present time, it has almost ceased to be practised.

Dry-point. A form of engraving which is usually classed with etching is produced by ploughing up the copper with a steel or diamond point in such a manner as to leave the upturned metal in a ragged edge or "burr" on the side of a furrow. For this purpose the tool is sharpened to an obtuse angle. No acid is used, the burr holding most of the ink which gives the printing quality to the plate; if the latter were removed, the line would print sharp and clean. Dry-point is sometimes used alone, but more often as a means of finishing an ordinary etching, it being capable of an effect of great richness of black. The plate worked in this manner is only capable of comparatively few impressions, as the pressure of printing soon flattens out and destroys the burr.

Etching Limited to Pure Line. In all the processes of etching it should be remembered by the beginner that he is dealing with pure line, and that, within this limit, the art registers the precise work of the artist. In a reproduction of a picture the aim should be to express in line the intention of the painter, and not to imitate the texture of paint. In the selection of a subject, one lending itself to a bold or graceful arrangement of line rather than of mass, or tone, will always be more satisfactory, and the merit of an etching lies more often in what is omitted, but still suggested, rather than in an extreme of finish. If the right hint is given by the etcher, the eye of the beholder cannot fail to fill in the scheme offered to him with absolute certainty and rare pleasure. The mistake must never be made of confusing an etching with a pen-drawing.

7. LA POMPE NOTRE DAME, 1852
(From an etching by C. Méryon)

Aquatint Etching. This is a method of etching which resembles that already described, so far as it is the result of biting-in a drawing upon copper with acid, and when once the plate is prepared, it exactly resembles it in the process of printing. But the essential difference between this class of print and etchings lies in the fact that in pure aquatint there are no lines. Everything is expressed in tones, as in a wash drawing, of which, indeed, it may be considered the engraved equivalent, as etching is that of pen drawing. This being so, there is no use for needle or graver. The biting-in is done by washes of acid applied with a brush, on a ground having certain necessary characteristics. And the preparation of this ground is, therefore, the first thing to be considered.

The principle underlying the various ways of obtaining an aquatint ground will easily be understood when it is remembered that the smooth surface of an unused plate will not hold ink for printing. It must be roughened in some way. To begin with, therefore, we require, for the purpose of painting acid on the plate, an even printing surface all over it. This is obtained by breaking up the surface into minute dots or reticulations, and can be effected by several methods of laying a preliminary ground, followed by acid biting.

Grounding the Plate. In one case, an ordinary etching ground is first laid upon the plate, which is then heated till the ground becomes soft. Upon this finely powdered salt is next sprinkled evenly. The salt sinks through the soft ground, until it reaches the copper. The ground is then allowed to become cold and hard again, when the salt can be dissolved out with water, leaving the ground pitted minutely wherever it rested. If the plate is now bitten in the acid bath, each of these pittings will produce a black dot. Another method, conveniently known as sand-ground aquatint, is to cover the hard ground with sand, or, better, with emery paper, and pass the plate two or three times through a printing press.

But more convenient than these are the processes known as the "resinous dust ground," and the "spirit ground." In the former, finely powdered resin or asphaltum is placed in a box, which is then shaken rapidly or revolved until a smother of the dust is produced inside. The plate is then inserted at the bottom of the box—and allowed to remain until the dust has settled in an even layer on its upper surface. It is carefully withdrawn, and heated gently, but not enough to melt the dust, a proportion of which will be found to adhere to the plate. The superfluous dust is blown away, and the plate, if bitten, will show a covering of infinitesimal white dots where the particles of resin or asphaltum adhering to it have protected its surface against the action of the acid. This method gives good results, but requires careful manipulation and a specially-made box, with an aperture and door for the insertion of the plate.

The most convenient of all ways of making an aquatint ground is by taking advantage of a curious property of resin. This is dissolved in rectified spirit, and flooded evenly over the plate. As it dries, the resin held in solution is again deposited, and contracts into a series of reticulations, each of which, if bitten, will be represented by a fine line where the acid has penetrated the "crackle" of the resin. The granulations produced will become coarser as the proportion of resin used is increased.

The Aquatint Picture and its Limits. In the making of the picture the high lights are first stopped out with Brunswick black. Acid, as already stated, is applied with a brush, each tint being similarly protected as finished, and the whole completed by successive steps in this manner, leaving the deepest shadows to the last. The method of printing is identical with that of an etching. Pure aquatint, as thus described, is by no means capable of a wide range of expression, although, for certain effects of landscape, it has unrivalled qualities. But its flatness of tone limits it to a considerable extent, and many artists have reinforced this by using a preliminary basis of strongly etched lines, put upon the plate before the

aquatint ground was laid. The history of the art begins with Jean Baptiste Leprince about 1750, although earlier suggestions of it are to be found. It was introduced into this country by the Hon. Charles Greville, who communicated it to Paul Sandby, R.A. This artist made the first English aquatint, in 1774, and his work [6], together with that of William Daniell, R.A., J. C. Stadler, R. and D. Havell, and F. C. Lewis, may usefully be referred to by the student. An aquatint plate, it may be noted, has good printing powers, and is capable of producing a large number of impressions without serious deterioration.

Line Engraving. The old and beautiful art of line engraving is now almost entirely abandoned; but its revival always remains possible. The technique of it is quite simple, but it requires a patient skill only attainable by long practice. It is to be remarked, in the first place, that the term "line engraving" is used to denote only engraving upon a metal plate, made with a special instrument—the burin [1]—which may be described as a short steel tool, curved upwards towards the point, square in section, but grooved on each face, and fitted with a knob handle suitable for holding within the palm of the hand. In the ordinary meaning of the words "line engraving," they might be applied to etching, dry point, or woodcuts; but the custom of ages sanctions the above limitation, which is universally accepted.

All the old engravings were made upon plates of copper until the early part of the nineteenth century, when steel was largely substituted for the softer metal, the term "steel engraving" thus coming into vulgar use almost as a synonym for that forming the title of this section. In pure line engraving no tool other than the burin was used. The subject was first lightly sketched upon the plate, and then gradually finished, the practice of most engravers having been to work from light to dark, gradually filling in the shading as the task progressed [5]. The burin was held in the palm of the hand, guided by the finger and thumb, and driven forward against a pad with considerable pressure, cutting a line almost free from burr [4]. But many engravers made use of the process of etching as a convenient means of getting the outlines of their subjects upon the plate, biting-in lightly, and reworking the lines with the burin.

How the Masters of Line Used its Limitations. At a very early period in the history of the art the dot makes its appearance as an adjunct to the pure line, and this is most easily made with a burin having its point curved downwards instead of up. The old masters kept their work open, using simple shading only to express form. Close cross-hatching—that is, lines crossing and re-crossing each other closely at varying angles—was a development due to attempts at realising the tone, and light and shade, of a painting or wash drawing. In this later work, the dot is used to strengthen, or as a substitute for the cross-hatching, instead of being simply a device to secure a softer effect than line was capable of giving.

The great characteristic of burin work is that it produces only a formal line or line and dot, as compared with the unfettered freedom of the etching. It will turn only in a curve, and thus imposes severe limitations on the skill of the engraver. The great masters of line, such as Dürer, Lucas Van Leyden, Mantegna, Marc Antonio, and our own William Rogers, were able to use this characteristic to splendid advantage, and the leaders of the Dutch and French schools—as, for example, Cornelius Visscher, Nanteuil, and the Drevets—while losing much of the intrinsic value of line, quite compensated therefor by the superb modelling and light and shade with which they invested their portraits. After the close of the sixteenth century line engraving was chiefly devoted to the reproduction of paintings; and the student of this class of work should not rest content until he has made himself acquainted with the admirable engravings which were produced in England by the artists associated with J. M. W. Turner, absolutely the finest landscape engraving the world has ever seen. It was usual to take proofs of the plates in various stages of completion. An interesting series of these can be referred to in the collection of prints and drawings in the Victoria and Albert Museum.

Stipple Engraving. This was a method much used in the second half of the eighteenth century. In it the whole of the picture is represented by dots, carefully placed, at wide or close intervals, to express the modelling and light and shade of the design. These dots were generally made with a needle upon a plate covered with an etching ground, and, when bitten in, deepened and finished with the burin. For this purpose, as already remarked, the burin has a downward point. The roulette, a small wheel with toothed surface, and tools consisting of groups of two or more points, were also employed. A combination of cut line and stipple is also frequently met with. A special form of stipple used particularly for the facsimile reproduction of drawings has received the name of "chalk engraving." It was executed partly with soft ground etching and partly with roulettes and punches. The best examples of stipple engraving—which was frequently printed in red or brown—are to be found in the work of F. Bartolozzi, W. W. Ryland, A. Cardon, G. Vendramini, and L. Schiavonetti.

Colour Prints. Mezzotint, aquatint and stipple, and even line engravings, were frequently printed in colours, the inks used being of the same nature as described above, but with the addition of pigment. Too often the use of colours was merely a device to disguise the wearing of the plate, and although a pleasing effect is produced in the best examples, this defect should always be watched for by the collector. The colours were arranged, as required, on the plate for each separate impression, and it is impossible, as a consequence, to find two prints in colour from the same plate, that exactly correspond in the minutest details.

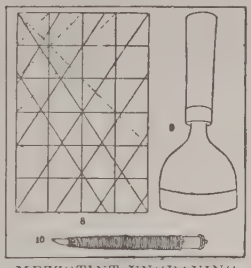
It is fairly easy to detect the extent of handwork which appears on a coloured aquatint or engraving. If it be examined with a lens, the spaces between the engraved dots or lines will appear white in those parts wherein the colour was printed; but where applied by hand, the wash covers everything. Good examples of coloured mezzotint and stipple are to be found in prints by the Wards and J. R. Smith—especially those after Morland; of coloured aquatint by W. Daniell and the Havells; and a good print of pure line engraving, printed entirely in colours, may be referred to—"A Sleeping Venus," by P. W. Tomkins, after Titian.

Engraving in Mezzotint. Of all the varying methods of engraving a metal plate, none is receiving more popular attention nowadays than the peculiarly British art of mezzotint—that is, so far as the productions of bygone engravers are concerned. The number of modern practitioners of the method is, however, small, and although some among them are no whit inferior in skill or taste to their predecessors, the

vagaries of fashion are such that they receive but a paltry measure of support from their contemporaries. Their consolation is that they are undoubtedly working to benefit future generations.

This manner of engraving differs essentially from all others, in that its practice entails the use neither of point of any kind nor of acid. The first essential is the laying of a ground, but this is, in itself, an integral portion of the actual graving to be done. Again, as with an aquatint, the need is to provide the whole surface of the plate with the means of retaining ink, but in this case it is done by roughening the plate with a tool. This is termed *rocking*. The tool used is of steel, somewhat resembling a broad chisel, but with its cutting edge shaped to the segment of a circle [**9**]. The outward face of this tool is regularly grooved to the extent, as a rule, of from 40 to 80 grooves to an inch. The curve is ground, from within, to an edge, which produces a point corresponding to each of the ridges between the grooves. It may be mounted with a short perpendicular handle, and so used, but for the preliminary laying of the ground is better affixed at a right angle to a rocking pole, the opposite end of which is provided with a free slot travelling horizontally between guides fixed to a table.

Rocking and Graving the Plate. The pole should be some 4 ft. long. The plate is held with one hand, while the tool is steadily and regularly rocked with the other, the motion causing it to pass in a straight line from one edge of the plate to the other, making a series of indentations as it goes, and at the same time ploughing up the copper to form a burr. In order to make sure that this roughening is equally distributed, the plate should first be marked out with guide lines for the rocker to follow, and these lines, termed *ways* [**8**], are arranged at various intervals and angles, by means of a scale. About 40 ways give a good ground, and continual re-sharpening of the tool is necessary during the operation. If the plate were now charged with ink and printed, the result would be a rich, velvety black of the finest quality attainable by any process of engraving.



MEZZOTINT ENGRAVING
8. "Ways" of rocking a mezzotint plate 9. Rocking tool 10. Scraper

The picture is produced by scraping away this ground with a broad-bladed, double-edged scraper, terminating in a point [**10**]. It becomes necessary, however, at this stage to bear well in mind what has been done to the plate. Highly magnified, the copper would present, in section, a series not only of elevation but of depressions. The mere cutting away of the burr to the original level of the plate would produce, when printed, only a middle tint, as compared with the full depth of blackness given by the undisturbed ground. To obtain the highest lights, the hollows must be cleared out, otherwise they would hold a considerable quantity of ink and print effectively. Between these two extremes of untouched burr and cleaned out indentations lie the possibilities of obtaining every shade and delicacy of tone in the whole gamut of monochrome.

The Charm of the Mezzotint. It will have been gathered from this description that line does not exist in pure mezzotint. Herein is one of the great difficulties of the art—that of obtaining adequate definition of form. At the same time, the universal softness necessitated by the process constitutes perhaps one of its most alluring charms.

It is usual in practice to transfer the outlines of the picture to be engraved by means of gelatine after the ground is laid. The work then proceeds from dark to light—care being taken to remove the ground gradually—keeping, so to speak, on the safe side until success is assured. The ink used is much the same as that used for an etching or aquatint. It must be thoroughly worked into the whole of the plate, and the superfluous ink then wiped off, particular attention being paid to the clearing of the high-lights.

From the time of its invention, by Ludwig von Siegen (whose first plate was made in August, 1642), until the early part of the nineteenth century, copper alone was used for mezzotint engraving. In 1820, W. Say produced a portrait of Queen Caroline, engraved on steel, and in 1822 the use of this material was perfected by T. Lupton, and for some time it had a considerable vogue. But it was never quite satisfactory. The burr was slighter, the indentations shallower, and it was much more laborious to work, while the dead black ink and white paper used lent themselves only to a limited range of effects, seen at their best in the engravings of David Lucas, after Constable. Moreover, the number of possible impressions was soon found to be little more than could be procured from copper; and since the modern process of steeling plates has been perfected there remains no good reason for the use of steel.

Combinations with Pure Mezzotint. So far we have treated only of pure mezzotint—that is, this method used by itself in the engraving of a plate. But the labour involved therein was so great that the process had hardly attained its full development before other methods began to be used in combination with it, for the purpose not only of saving trouble, but of avoiding the difficulty of defining outlines already alluded to. R. Earlom was one of the first artists to give attention to this endeavour; he frequently employed stipple etching, both as a groundwork and in order to elaborate his detail. In the "Liber Studiorum" (1807-1819) J. M. W. Turner employed generally a combination of etching and mezzotint, using the first process to bite in the strong lines of his composition before handing over the plates to be completed by mezzotint engravers. In the hands of Samuel Cousins, what is called mixed mezzotint was pushed to its utmost limits. He and his contemporaries made use of a heavy roulette as well as of special rocking tools, and also used stipple etching and even aquatint. But these practices do not add to the real artistic merit of an engraving, and it is significant that they were but the prelude to an almost complete decay of the art. The student should study the works of Valentine Green, J. R. Smith, J. and W. Ward, and J. MacArdell.

Steel-facing. The printing powers of etched or mezzotinted copper-plates are very limited. The former class may produce 200 or 300 good impressions, but the latter (and the same applies to drypoint) cannot be relied upon to give more than from 30 to 100 prints of the best quality, owing to the rapid wearing away of the soft metal in the press. An attempt was made, as we have seen, to overcome this difficulty by the substitution of steel for copper, but without success. During the last

two decades science has come to the rescue, and has provided a means whereby the actual engraving having been done upon copper, and full advantage taken of its unrivalled adaptability to this purpose, it may be invested with the durability of steel. The following concise description of the process (by Mr. Frank Short, A.R.A.) is taken from a pamphlet published by the Board of Education, and may be accepted as authoritative :

"Copper-plates when ready for printing are often covered with an exceedingly thin facing of steel (or iron) by suspending them in an iron solution and passing an electric current through it. The copper is covered, almost instantaneously, with a coating of hard, bright iron. From three to twenty minutes may be needed to obtain a sufficient thickness of iron, according to the plate and the current employed. Many solutions containing iron may be used, but the simplest method is to fill the tank with water in each gallon of which is dissolved 1 lb. of sal ammoniac. A large iron or steel plate (the anode) is then placed permanently in it, and attached to the positive pole of a battery (or other electric current), and a small piece of steel (generally an old file) is temporarily suspended opposite to it, attached to the negative pole, until the bath becomes sufficiently full of iron to cause a deposit on a copper-plate when placed in it.

"The plate to be steel-faced is suspended by a strip of copper, soldered temporarily to the back, which serves both as a support to the plate and to complete the circuit of the electric current by contact with a brass rod connected to the negative pole of the battery. The quantity of current passing must be proportionate to the surface of the plate to be steel-faced, and its intensity may vary from 1½ volts to 6 volts. It is essential that the copper should be chemically clean before it is put in the bath, and it is necessary to remove it from the bath every few minutes to wash and gently polish the surface with a paste of fine whiting and water, applied with a flannel, in order to keep the coating clear and bright.

"The steel-facing can be easily removed, when desired, by placing the plate in a mixture of nitric acid and water (1 acid to 7 water), which instantly dissolves the steel, leaving the copper untouched."

A good many wild statements have been made as to the effect of this process, and these need to be corrected. In the first place, it not only does not result in any loss of quality in the print, but it is impossible for the most accomplished expert to decide, from an inspection of proofs, whether they have been taken before or after the plate was steel-faced. Secondly, it does not prolong the life of the plate to the extent that has been claimed. It only makes it possible to produce some few hundred impressions—not thousands—of the best kind.

11. CHRIST BEFORE HEROD
A woodcut by A. Dürer, 1509

Wood Engraving. The old and beautiful art which made use of wood as a material for the printing of the artist's design has almost vanished under the stress of the competition set up by modern photographic processes. But it is so simple, and capable of effects so fine and characteristic, that many hope for its revival.

At the outset we have to indicate an essential difference between the wood-block and that made of metal. In the former the printing is done by the upper surface of the block, exactly as with type. The process is, in fact, *relief printing*, as opposed to the *intaglio printing* of the metal plate, in which the paper is forced by great pressure into hollows excavated in the metal. As a consequence, wood-blocks can be inserted in type without difficulty, and the paper shows no sign of that depression which is known as the plate-mark.

The Dürer Wood-cutting School. There are two methods of using wood for engraving. That employed by the great school of Albert Dürer [11], and for many years afterwards, was executed upon blocks cut plankwise—that is, parallel with the grain. A wood of comparative softness, such as that of the pear-tree, was chosen. The drawing having been made or traced upon the smooth surface, the lines thereof were outlined with a knife, and the superfluous wood cut away with convenient tools, so as to leave the design intact. To this method it has been found convenient to restrict the term "wood-cutting." It is, in all essentials, that employed by the Japanese in their colour prints,

The Bewick Wood-engraving School. At the end of the eighteenth century it was found that boxwood, from its extreme hardness and closeness of grain, was especially suitable for a use to which the term "wood-engraving" is well applied. The blocks were cut not with the grain but across it. The drawing was made upon the block, on a surface prepared for the purpose with Chinese white, and the engraving executed with burins of several sizes. The driving of the burin through the wood produces a white line, the ink being held by those portions of the block untouched by the tool; and this fact was made use of by Bewick and the best of the nineteenth century wood-engravers to produce their effects. Prints by these artists will be seen, on close examination, to consist of a series of white lines or dots, each made with deliberate purpose of expressing drawing. But the burin was also used for facsimile engraving, with a result similar to that of the knife, developing in this respect into a laborious reproduction of the exact lines of the artist's work, as compared with the individual translation of it secured by the white-line method.

The work of Bewick exemplifies the latter; that of Charles Keene in "Punch" is an admirable exposition of the former. EDWARD F. STRANGE

Conditions of Entrance and Service in the British Navy. Seamen and Artificers. Pay and Promotion. The Air Service. The Royal Marines.

THE ROYAL NAVY

THE Royal Navy appeals alike to the patriotic and the adventurous instincts of a boy. The modern tendency towards comfort has shorn the Service of its hardships, except those which are unavoidable in war-time for all active combatants; and the opportunities for advancement make an appeal to a lad who loves the sea, and is willing to work hard at an interesting career for a living wage and a comfortable pension. As the science of war advances, so does the standard of intelligence, and today it is necessary for a Navy man not only to be strong, but also to have brains to direct his energy aright. For the past fifty years the class of sailor has been improving, till now he ranks high among the skilled workers.

So high is the standard of efficiency required of petty officers that the barrier between the officer and man is no longer insurmountable, and a youth who enters the Navy at the age of 16 may well hope to reach a commission before he retires from the Service. Even should the hope fail to materialise, his training will have assured him an excellent prospect of obtaining civil employment ashore.

How to Join the Navy. Application may be made to the station officer of any coast-guard station; to the Royal Marine recruiting staff officer at Belfast, Birmingham, Bristol, Exeter, Glasgow, Liverpool, London, Manchester, Newcastle-on-Tyne, Nottingham, Southampton, or York; to the Commodore of the Royal Naval Barracks at Portsmouth, Devonport, or Chatham, and the naval recruiting officers attached to those ports, and to Oxford and London (East); or at one of the outlying stations which are scattered through the large towns of the British Isles.

The conditions vary from time to time, but it may generally be understood that a youth or man who possesses the qualifications set forth in the table may expect to be admitted as far as his physical requirements go. It should be observed with regard to chest measurement that the examining officer notes particularly the difference between the size of the expanded and contracted chest. This difference should not be less than two inches.

In reply to an application, a form is supplied to the candidate, which he is required to fill up, and if his replies be satisfactory he is provisionally examined. He is then sent to one of the depots for a final medical examination, the trade test (if the candidate desires to enter one of the trade openings), and a simple educational examination. If he fails to pass, his fare is paid home.

The physical standards required of candidates for the Royal Navy are as in the table on this page, but boys of good physique and education are sometimes accepted although slightly below the standard.

While the present war lasts, candidates for the ratings of seaman, stoker, engine-room artificer, and other trades may enter up to the age of 38, or 40 in special cases for service during hostilities only.

Special Service. There are two varieties of service—continuous and special. A Special Service man enters between the ages of 18 and 25, agreeing to serve for the first five years with the Fleet, and for the remaining seven years in the Reserve. After two years' service, however, he may re-engage to complete eight years with the Fleet and four years with the Reserve. He may earn one good-conduct badge at the end of his first three years' service. This bears 7d. a week extra pay. On transfer to the Reserve, with a retainer of 6d. a day, the man is liable to one week's training every year. In case of national emergency he is, of course, obliged to join the Fleet If, after his 12 years' service is complete, the reservist elects to continue to re-enrol for successive periods of five years, he will receive a gratuity of £50 when discharged on completing 20 years' combined service in Fleet and Reserve; but no man will receive the gratuity or be released from liability for active service until he reaches the age of 40 years. A Special Service man, be it observed, has no chance of rising to warrant-officer rank.

Ship's Stewards or Writers: No fixed physical standard		

NOTE. These standards are liable to alteration according to the supply of and demand for recruits.

Stokers may enter the Navy in the Special Service class in much the same fashion as seamen. They must complete five years in active service and seven in the Reserve, but can re-engage for eight years

and four in the Reserve. Good-conduct badges can be won in the same way as we have outlined above, and the gratuity on completing 20 years' combined service is the same. Special Service stokers do not, as a rule, rise above the rank of leading stoker, and it is hardly possible to rise even so far in the five years.

After two years' Special Service, men who pass the examination for able seaman or stoker and are strongly recommended may transfer to Continuous Service. They then become eligible for the higher ratings, and their Special Service is reckoned towards the 12 years' engagement. Apart from such a step, it may be said that in the Special Service there is no great prospect of a career. It is, however, an avenue for the men of the Mercantile Marine. They have five years' training, which is most valuable on returning to their civil occupation, and it secures them a retaining fee, which is a useful addition to their wages.

Continuous Service. Men of all ratings, except officers' stewards and cooks, sign on for 12 years, at the end of which time they may re-engage for another 10 years to complete their service for a pension. At the end of 22 years' service they may retire with a pension, or they may be allowed in special cases, if their conduct has been all that could be desired, and if they have progressed satisfactorily, to serve until the age of 50, with an increase to their pension for every year's further service as petty officer. To qualify for the long-service pension they must belong to the Royal Fleet Reserve up to the age of 50.

Men disabled or invalided out of the Service are dealt with fairly generously on a sliding scale by pension or gratuity, according to the nature of their disablement and the circumstances in which they are placed. Men disabled in the execution of their duty are awarded life pensions, irrespective of the length of their services. Furthermore, a grant of £22,000 a year is made by Greenwich Hospital for the assistance of seamen or Marines who have no naval pension or whose pension is small. Pensions to widows, etc., are another feature of the benevolent side of the Service. Another most excellent institution is the Greenwich Hospital School, where 1000 sons of seamen and Marines are educated and maintained free of cost. In addition, 100 boys and 150 girls are supported at various homes.

All men, whether for Continuous or Special Service, receive a free outfit, including a set of bedding. In addition to their pay they receive free rations on a scale greatly improved in recent years. Out of this, by careful management, it is possible to effect "savings," which are credited to the man, and go to buy luxuries.

Boys. A boy must be of good character, must produce a birth certificate, or a declaration made by his parents before a magistrate that he is of the proper age, and (if under 17) the written consent of parent or guardian to his entering the Navy and to his agreeing to serve until he has completed 12 years' Continuous Service from the age of 18. At present a boy may enter, if he wishes, for the duration of the war only. He must be able to read and write a passage from a Standard IV. reading-book, to write a similar passage from dictation, and to have a fair knowledge of the first four rules of arithmetic.

On acceptance, the boy is sent to a harbour training-ship, and is provided with a free outfit of clothes and bedding. After six or twelve months' training on board the harbour-ship the boy is drafted

PAY OF WARRANT OFFICERS, PETTY OFFICERS, AND MEN.

NOTE. During war-time, a Separation Allowance is paid to wives and children.

to a sea-going training-ship to gain a knowledge of seamanship and gunnery.

The cruise ended, and the boys having reached the age of 18, they are sent to take their place in the ranks of the Navy as ordinary seamen. No examination is required for this rating, and it is only now that the ambitious young man has a chance of showing what he is worth. He goes to sea in one of His Majesty's warships, and he has the opportunity of learning from his officers and the instructors something practical of gunnery, seamanship, and sufficient engineering practice to pass his examination for able seaman.

Examination for Able Seaman. The examination for able seaman is of the most practical nature imaginable, and consists of the following tests.

A fair knowledge of steering a ship, heaving the lead, rowing, knotting and splicing (hemp and wire rope), and general duties of seamanship; gunnery, torpedo, and field training, which he has learnt

during his novitiate. He must be able to use simple engineers' tools and do ordinary stokehold work, such as sweeping tubes, cleaning boilers, and the like. He must also have a knowledge of bunker-work, firing, and watchkeeping, all of which he will have learnt during his 30 days' course on board ship, during which time he is attached to the engine-room staff and is under the orders of the engineer. Furthermore, he must be able to make and read slowly a signal in semaphore, and understand the use of the flags used in flag-signalling.

As able seaman he will turn his mind to gunnery, and will receive instruction in gun-laying, sight-setting, and so on, from the gunnery lieutenant and the gunner, and in torpedo work, so as to gain the badges of seaman gun-layer, or seaman torpedo-man, or turret gun-layer, etc., each distinction earning him a badge, and each badge carrying with it a small increase of pay, varying according to the qualification.

He will bear in mind also the good-conduct badge which he will be permitted to wear after three years' service as seaman, with a "very good" character from his captain. These badges, awarded at the end of three, eight, and thirteen years' service, carry with them extra pay at the rate of 1d. per day each.

Leading Seaman. Leading seaman is the next step in the sailor's career, which means that he is a good helmsman and leadsman, able to assist in sailmaking and repairing; a practical rigger. He must have a thorough knowledge of the practical side of gunnery; he must be able to make and read semaphore signals, and he must know the use and colours of such flags and pennants as will enable him to look out a signal in the boat's signal-book. His examination is carried out in a sea-going ship, and qualifies him for promotion to second-class petty officer.

Petty Officer. As petty officer the man must, to a certain extent, remodel his existence. He is now in authority; he is directly responsible to his superiors that discipline is maintained, and that the men under his charge do their duty efficiently. By this time he will have made up his mind whether he prefers the duties of mere seamanship and the working of a ship, or whether the guns attract him more. In the first case his goal will be that of boatswain, and in the latter he will aspire to the position of gunner.

It is of the highest importance nowadays that men should take the earliest opportunity of qualifying in gunnery and torpedo work, for the war has directed even more attention to these branches of a seaman's education than in normal times, and it may quite easily happen that his promotion will be very seriously retarded by the lack of a certificate.

Ultimately the seaman reaches the rating of chief petty officer or warrant rank (gunner or boatswain), when he drops the bluejacket's characteristic garb for the blue cloth coat and peaked cap, or "fore and aft rig," as the sailors call it.

Chief Petty Officer. Candidates for chief petty officer are not put on the roster until they have five years' service, with a very good character. Then their names are put down for promotion, and in due course they are selected by seniority, tempered by selection, on the reports of service and attainments. Since a warrant officer or a chief petty officer comes into close contact with the officers of the ship, it is most desirable that he should have taken every possible step to improve his education and his manners, in the time of waiting, by the assistance of the instructor and by some private study.

Chief petty officer or warrant officer is the highest position reached by the majority of seamen, but a few still higher posts are available. Chief gunners and chief boatswains nowadays hold what are known as "lower-deck commissions"—that is, they are commissioned officers of warrant rank, who continue to associate with the warrant officers and chief petty officers of their ship. The man for whom this article is written, however, will aspire to climb yet one step higher—to the commissioned rank of lieutenant. For this rank it is essential that his education should be excellent, for he may have to live in the ward-room with college-trained officers, and this point is taken into consideration in selecting men for commissions.

Gunners and boatswains, and petty officers who have passed in seamanship for warrant rank, may be chosen for this distinction if not over the age of 25 years. After qualifying in certain subjects, candidates are given the rank of acting mate, being classed as ward-room officers and receiving 8s. a day pay and 2s. messing allowance. A spell of further instruction follows, and the selected candidate becomes a mate, with the relative rank of sub-lieutenant, being also eligible for further promotion to the grade of commander. Warrant officers under 45 years of age who distinguish themselves by acts of gallantry and daring may be promoted to be full lieutenants.

Promotion in the Navy. To give some idea of the rate of promotion in the Navy, it may be said that in peace-time a smart young man with a fair education might hope, with luck and diligence, to reach the rank of second or first class petty officer by the time he is 24, and to become chief petty officer at 28 or 30 years of age. Warrant rank would come in about the same time. War naturally quickens promotion very greatly for the fit and the fortunate.

It should not be forgotten that for chief petty officers and warrant officers there are many good shore billets in the shape of instructorships at the colleges, at torpedo and gunnery schools, which not only carry with them a handsome increase of pay, but provide a most comfortable home for a man who has, perhaps, tired of the perpetual change of quarters which the exigencies of naval service involve. These go, of course, to men who are favourably reported to headquarters as being energetic, trustworthy, and who, by their application to the theoretical side of their work, have fitted themselves for the posts.

Engine-room Staff. Boys may be entered as boy artificers between the ages of 15 and 16, after passing the usual medical examination and an educational test of ability to read and write. They agree to serve for 12 years' continuous service from the age of 18.

On entry, the boy artificer is placed on the ship's books for training at one of the home ports, and for the first four and a half years is learning his trade as a workman under an instructor; is instructed in steam and general engineering subjects by an engineer instructor, and in general knowledge by a schoolmaster. His duty in life will be the care and repair of engines, as compared with the stoker class, whose business is to drive them. After the 4½ years' course, and a final examination in the subjects studied, he is classed as an engine-room artificer, fifth rate. He goes to sea for about a year, and if he proves efficient he is rated as acting engine-room

artificer, fourth class. It is possible for a practical engineer between 21 and 28 years of age to enter direct if he is able to pass the examination, which is as follows: A knowledge of the first four rules of arithmetic; ability to read and write well enough to record the working of engines and boilers; a general acquaintance with the names, uses of parts of marine engines; ability to run engines and to effect the ordinary repairs of an engine-room. Candidates who hold a Board of Trade engineer's certificate, first or second class, are excused this examination. After one year's service as acting engine-room artificer, fourth class, the man, on obtaining a certificate from the captain that he is capable of taking charge of a watch in the stokehold, and that he is an efficient workman worthy of confirmation in his rank, becomes a fourth-class artificer.

After three years' service above the rank of fifth-class artificer, he passes to third-class artificer; in seven years to second-class artificer, and after 12 years' service, if he engages for another 10 years, to engine-room artificer, first class. Above this lies chief engine-room artificer, second class, for which he must pass an examination in arithmetic up to vulgar and decimal fractions, and show his practical knowledge by being able, for example, to estimate bunker capacity or a cylindrical oil tank's contents. His knowledge of engineering must be wide and practical. He must know the best methods of prevention and cure of ordinary engine and boiler room casualties; must understand the management of boilers generally, and the running and use of valves; have a good knowledge of indicator diagrams and the calculation of horse-power; understand the adjustment of bearings and the fittings of brasses.

Six years in this rating qualify him for chief engine-room artificer, first class. Chief engine-room artificers of 29 years of age are eligible for advancement to warrant rank on passing the examination for artificer engineer, and receive a gratuity of £25. These, again, may pass to chief artificer engineers, from whom, by selection, there are chosen a few engineer lieutenants.

Stokers. The men who tend the boilers are in a far better position today than they were formerly. "Once a stoker, always a stoker" used to be the saying; but now, by good conduct and willingness to work at the theoretical side of his trade, the stoker can rise to be chief petty officer, and even attain warrant rank, though few stokers expect the latter. An able-bodied man of good character and physical development, without previous experience, may enter as second-class stoker. After a period of instruction in his duties and in rifle, pistol, and cutlass drill (for a stoker must know how to fight nowadays), he is promoted to first-class stoker on completing a year's service.

After four years' service comes a short course of instruction, followed by a test examination, and, that being satisfactorily passed, he becomes leading stoker. After serving in this capacity he is eligible for advancement to acting stoker petty officer. It will now be necessary for him to work hard at his education if he wishes to rise further. He must attend a torpedo course to give him a knowledge of the engines and general working of these weapons; and after having served ten years in stoker ratings he may be promoted to chief stoker, which ranks as chief petty officer. The examination is the same as for leading stoker, but in addition he must have a general working knowledge of the parts and uses of engines and boilers. Acting leading stokers who have been selected for special ability are eligible to be rated as mechanicians, rising to warrant mechanician and chief warrant mechanician when they take charge of engines.

Signalmen. Signal boys are selected from the smartest of the second-class boys, or, if vacancies occur, from among the first-class boys. Occasionally they are entered direct from Greenwich School. They are given an elementary signal course, lasting some three months, and are taught the elements side by side with their instruction in seamanship. The work requires keen eyesight and a lively intelligence, for a signalman is one of the most responsible men in the ship.

The next step, that to ordinary signalman, is reached when the boy is over 18. The aspirant by that time must have gained a working knowledge of day and night signals. For this and the higher ratings men are not obliged to qualify in the same fashion as an A.B., but are exercised in gunnery and musketry. For the next rating of signalman is necessary a good working knowledge of day, night, fog, gun, and sound signals as applied to fleets, ships, and boats, as is a proficiency in the use of the Morse code, semaphore, and flash signals.

After a sufficient experience as qualified signalman a man is advanced to leading signalman, when he must be able to undertake the duties of a signal petty officer, and must understand the regulations for prevention of collisons at sea. Good men with experience are then promoted to yeoman of signals. Chief yeoman and signal boatswain are the next steps in the signalman's career, the appointments being made by seniority, tempered always by selection of the best workers and the steadiest men.

Wireless Telegraphy. Like the signal section, this branch is recruited from smart boys of the seaman class who have finished their harbour training. They undergo a special course of instruction, and at 18 are eligible for the rating of ordinary telegraphist. From this they progress according to ability, through grades equivalent to those of the signal branch, up to warrant rank, commissioned warrant rank, and, in exceptional cases, to that of full lieutenant.

Air Service. Candidates for the Royal Naval Air Service must have had experience in the construction or repair of aircraft, the care of petrol engines, motor-driving, cycle-making, or boatbuilding, or as electricians, coppersmiths, or carpenters. They are normally required to enter as mechanics for four years' active service, and four years in the reserve. During the war they may join for the duration of hostilities. Young unmarried men already serving in the Navy may be allowed to transfer to this branch. Experienced artificers entering the Air Service are rated at once as petty officer mechanics.

Airmen may be detailed for any branch of the service, whether seaplane, aeroplane, airship, seaplane ship, or kite work. It by no means follows that every member of the Air Service learns to fly. Only those who appear to have the special qualities needed for successful flight are chosen to be trained as pilots. An airman so selected receives an extra 1s. a day while under instruction, 2s. a day when he gains a second-class flying certificate, and 4s. as soon as he holds one of the first class. The crews of airships are paid 2s. "flying pay" daily while so employed.

Naval Craftsmen. A few boys between 14 and 16 years of age are eligible for service as boy shipwrights. They have to pass the Civil Service examination laid down for dockyard

apprentices, and agree to serve for 12 years after the apprenticeship, and are instructed in the yard until the age of 18, when they go to sea for training if they are found to be fit for the rating of carpenter's crew.

Among the skilled tradesmen entered for service ashore and afloat are the electrician, the carpenter, and the shipwright, the armourer, blacksmith, and the cooper.

Young men of good character between the ages of 18 and 28 who are sufficiently good carpenters to do panelling, dovetailing, and sash-making may join, with the prospect of ultimately rising to petty officer joiner.

Shipwrights. Skilled workmen with a good knowledge of shipbuilding in wood, iron, and steel, and of repairing boats, are admitted between the ages of 21 and 28 as naval shipwrights, with the rating of petty officer. They are eligible for promotion to chief shipwright, and to the warrant rank of carpenter, while specially able and well-educated men may attain commissioned rank as carpenter-lieutenants, with pay at the rate of £237 to £273 a year. Competent naval shipwrights who complete their time for a pension can obtain similar employment in the Government dockyards on quitting the sea.

Coopers who pass a trade examination in making a bucket, also armourers, plumbers, and cooks, with a knowledge of their respective trades, can all join the Navy with the prospect of rising to chief petty officer in due course.

Electrical Artificers. The electrician is another of the skilled tradesmen who are always welcome in the Navy. He must be between the ages of 21 and 28, and must have had five years' practical experience as fitter and turner, or instrument maker. Men are preferred who have some knowledge of electricity or who have gained their experience in electrical shops. The candidate must pass an educational examination equivalent to school Standard VI.; he must know arithmetic up to vulgar and decimal fractions, and be good at dictation and reading. The practical part of the examination consists in relining and readjusting metal bearings, metal turning and screw cutting on a lathe, and repairs to electrical apparatus and instruments.

During his training the electrical artificer enters the torpedo school, and goes through a course of instruction, at the expiration of which he has to pass a further examination in repairing and fitting electric motors and all electrical instruments required in the Service. He must gain a good knowledge of the construction and repair of Whitehead torpedoes, and he must understand the intricacies of electric lighting and wireless telegraphy. After six years' approved service, of which three must have been spent afloat, he is eligible for promotion to chief artificer, second class. The rating of warrant electrician lies at the end of the service after a thorough examination in every branch of the art.

Sick-berth Staff. A limited number of young men between the ages of 18 and 22 may join the Service as sick-berth attendants if they can produce evidence of very good character, and have an elementary education. Selected candidates are accepted on probation, and go through a course of training at Haslar Hospital. They rise from sick-berth attendant through the grades of sick-berth steward, to chief sick-berth steward. There are a few shore berths open at Royal naval hospitals as wardmasters, and in the warrant rank of head wardmaster, but promotion is not rapid; and unless the candidate has a special liking for the work, the position is rather trying.

Writers and Ships' Stewards. These ratings are being filled at present for the term of hostilities only. Candidates must be smart men, of good character, not less than 18 years old. They are examined in spelling, writing, and arithmetic; and, in the case of writers, in typewriting and shorthand also. The latter class are employed in correspondence and keeping accounts on board ship, while the duties of ships' stewards relate to the victualling and clothing of the crew.

The Royal Marines. The Royal Marines are soldiers with sea training and sailors capable of military duty; they are experts in artillery work, yet they can pull a boat as well as any seaman. About two-thirds are serving in detachments in seagoing ships, while the other third are at their various depots, undergoing courses of infantry and artillery training. The advantages of the Service are change of scene and occupation, greater freedom of action than is enjoyed by soldiers, a wider field of training, and better pay. There are two branches—the Royal Marine Light Infantry (the Red Marines) and the Royal Marine Artillery (the Blue Marines).

Entrance Conditions. Young men from 17 to 23 years of age are eligible, provided they can pass the medical test and can read and write, and know the first four rules of arithmetic. On acceptance, they are forwarded to Eastney Barracks, Portsmouth, if for the Royal Marine Artillery, or the Depot, Deal, if for the Royal Marine Light Infantry. Normally the Marine must join for 12 years; but owing to the European war, recruits for the Light Infantry only are specially accepted for three years, or the duration of hostilities, and in that case must be between the ages of 19 and 30. Free kit and bedding are issued to every man.

The infantry recruit, after completing a course of infantry drill, swimming, gymnastics, and musketry, is drafted to one of the three great stations—Chatham, Portsmouth, or Plymouth—which becomes his home ashore, as is Eastney Barracks for the artilleryman.

Work of the Royal Marine. On completion of the above-mentioned instruction, the recruit undergoes a course of field training and heavy-gun drill, and in about 15 months is considered a qualified man. He is then available for sea service, and, as soon as the exigencies of the Service allow, is drafted to one of his Majesty's ships. If his ship be serving in home waters, this period will be from one to two years, but if abroad it will be probably three years before he sees his "home" again, when he will take his leave on full pay, and come back to requalify in shore work. Promotion to the superior ranks is not so rapid as in the Line regiments of the Army, but he may expect to be promoted to corporal within five years, to sergeant in 10 years, and to colour-sergeant in 16 years. There are also a few quartermasters' and warrant officers' positions open by selection and seniority to non-commissioned officers. The educational standards required of the various ranks are the same as those of the Army for an infantryman, promotion being dependent on the passing of these examinations, and also on the sea service completed.

Bandsmen. Marine bandsmen join the service between the ages of 15 and 23. They must be able to read and write, and have some musical knowledge. They are sent for training to the Royal Naval School of Music for instruction, and at the age of 18, or when fully trained, they become available for service. The pay ranges from 4s. 8d. a week for boys to 38s. 9½d. for the highest ranks, with an allowance of 1s. 2d. per week for instruments, and good-conduct pay up to 3s. 6d. per week.

Different Classes of Catalogues. Preparing a Trade List. Export and Special Lists. Retail Catalogues and Departmental Lists.

CATALOGUES AND PRICE LISTS

One of the most important branches of advertising is the preparation and distribution of business catalogues and price lists. No matter whether the firm be a wholesale house, a retail establishment, or a manufacturing concern, if it has a business of any size it must issue a price list for the information of would-be customers, where detailed particulars can be obtained of the goods the firm sell.

The preparation of the catalogue is, however, not such a simple and straightforward matter as it may seem at first sight. Apart altogether from the question of production in an attractive form, it must first of all be clearly decided to whom the catalogue is to appeal, for what particular class of people it is intended.

Different Classes of Catalogues. Catalogues and price lists may be divided into three main classes—(1) those that are intended for the trade—that is, for the use of the retailer; (2) those that are intended for the consumer—the members of the general public; and (3) those that combine something of both characters, and are intended for the trade, but are so prepared that they may be shown by the retailer to his customer. The first class of list is that issued by the manufacturing firms throughout the country, small and great, and by the wholesale houses; the second is issued by the large stores like the Civil Service, Army and Navy, etc., and by the better class of tradesmen, such as grocers in a good way of business; the third are issued by such firms as hardware manufacturers, makers of gas and electric-light fittings, etc., and enable builders, ironmongers, and so on to show a variety of designs to their clients without the necessity of keeping the actual articles in stock. In such cases the client selects his design from the pictures in the catalogue, and pays the price therein printed, the dealer getting a substantial discount off this price from the manufacturer.

It will be realised, with a little thought, that these three classes of catalogues are entirely different propositions, and must be approached in different ways. Then, again, in each class different businesses need entirely different treatment; and whereas an engineering firm in an extensive way of business may need a very large catalogue—large both in the number of pages and in the size of the page—because of the great variety of lines it turns out, and the need for well illustrating many or all of these, the makers of some household commodity, such as an infants' food, or jams and jellies, or a cocoa, may need a comparatively small price list, because the number of lines produced is very limited; the vast turnover is done in one or two articles only.

In the case of a retail price list, too, the size may vary from a twenty or thirty page list issued by a suburban grocer to a great volume of fifteen hundred pages or more, strongly bound in cloth, thumb-indexed, and illustrated with thousands of pictures, like the lists issued by the great stores. Such catalogues are veritable encyclopædias of the articles used by people in everyday life, ranging from clothes, games, furniture, and books to foods, soaps drinks, and medicines.

General Principles to be Followed. In planning out a catalogue, whether it be for the trade or for the consumer, there are a number of general principles that must be taken into consideration. And the first is that the list must be got up as attractively as possible consistent with reasonable expenditure. This statement needs elaborating. It goes without saying that a cheap and nasty price list, badly printed on common paper, with poor blocks and ugly type, is a bad advertisement. But in producing the list it does not follow that all firms are to go to the opposite extreme, and turn out catalogues that are works of art, beautifully printed in choice types on calendered paper, with rich blocks, the whole being splendidly bound in cloth. Such a list would, of course, be an excellent advertisement, but the cost of production may be so great as to increase the selling cost of the goods beyond what is remunerative. Then the list becomes a losing proposition. Some high-class articles on which there is a very large margin of profit may warrant the catalogue that rivals a magazine in appearance, but the style of the list in all cases must depend upon the amount of money that can fairly be devoted to it, and this must be arrived at by the heads of the firm after careful consideration.

Then a list should be as comprehensive as possible, and this for two reasons. In the first place, it should be in actual fact what it professes to be—a list of the things manufactured, dealt in, or supplied by the firm issuing it; and no one going to the list to look for a certain article supplied by the firm should fail to find it there, with all necessary details explicitly set forth.

In the second place, the mere fact that the catalogue is complete, and has other lines besides that for which a customer may consult it, is likely to result in business, for many an article is bought by the consumer, or stocked by the retailer, not because he wanted it definitely in the first place, but because he was attracted to it by seeing it portrayed and reading a description of it. This is why price lists should as far as possible be well and copiously illustrated. Even a common, everyday article like cocoa, jam, or salt may sell, where it would not otherwise do so, because it is nicely packed, and the package makes an attractive show in itself and when reproduced as an illustration.

A third principle to be followed in the preparation of a catalogue is that it should always be clearly and systematically arranged, so that anything that is looked for can be quickly and readily found; and however small the list may be, and however few the lines referred to in it, it is always wise to have an index.

Blocks for Price Lists. As the question of the kind of blocks to be used in a list applies equally whether the list be for the trade or for the consumer, a word or two may be said here on this subject. Where an art paper or an imitation art paper can be used, the blocks should, of course, be

half-tones of as fine a screen as possible. The technicalities of block-making are dealt with in another part of this book. For many articles photographs make better pictures than drawings, as in the case of machinery and clocks, etc., for example; but for things like furs, dresses, hats, and so on, drawings can be made to give a better idea of the article than photographs. Even in the case of machinery it may sometimes be an advantage to have a drawing instead of a photograph, so as to bring out clearly some particular feature of the mechanism.

If the paper has a not very glossy surface, then the screen of the blocks should be coarser, or the blocks will get clogged with ink in the printing, and the pictures will be smudged and muddy. For papers that have no surface, rough papers and common papers, it is better not to risk half-tones, but to use process blocks made from line drawings, or wood-blocks. These, if well done, can be made to give quite a good effect, certainly infinitely better than badly printed half-tones.

The Selling Force of a Catalogue. Many firms when they start to prepare a catalogue overlook the fact that it is, or should be, advertising. They think that so long as their various lines are mentioned and illustrated, all that is necessary has been done. Others go a little further, and see that a thoroughly competent printer takes real pains in producing the work artistically and well. The printing is good, the type is attractive, and the blocks are well made and well reproduced, but from beginning to end the book has no selling force.

Now, the first step in producing an effective price list is to have the right matter. The catalogue is not the same thing as a booklet, and cannot have a long and connected story about the firm and its goods, but, very briefly told in a few words, there should be something said about the various lines, some reason given why the tradesman should stock or the public should buy the article. This need not take up a great deal of room, but in the baldest of trade catalogues it will tell. In fact, it is almost better to have a good selling list printed in second-class style than to have a list first class from the typographical point of view but inferior from the advertising, and therefore the selling, standpoint. Certainly, success depends as much upon the matter as upon the get-up of the list.

Preparing a Trade List. The first thing, then, in preparing a trade price list, as it is in preparing all kinds of catalogues, is to get the matter together. This must be arranged in the proper sequence, the various lines kept together in their classes, and every size and style of package in each line set forth clearly, with its price. Thus if it is an engineering catalogue, and a certain pattern gas-engine is made in three different sizes, each must be referred to, with full particulars as to dimensions, horse-power, size, price, etc. Or if the list is that of a jam and marmalade firm, each size package must be mentioned and priced, one pound, two pound, three pound, seven pound, fourteen pound, etc.; and if these sizes are packed in various styles of receptacles, as in glass and stoneware, then each size in each style must be set out, with its price. Where a commodity is sold in bulk the bulk price must be given; and if goods are sold in cases and the cases are charged for, this, with the price per case, must be stated. The allowance, if any, for returned empties should be clearly mentioned; and where goods of the same class are sold in assorted lots the make-up of the assortment should be set out for the guidance of the buyer. In some instances it is wise to give the weights and measurements of the cases.

There should always be a page of general information, and very often the second cover—that is, the inside of the cover in the front of the list—or the title page is used for this purpose. There should be stated the terms and conditions on which the firm does its business, the various addresses of its branches and depots, its telegraphic address, telephone numbers, codes used, and any Royal and Government appointments it holds.

Illustrations for a Trade List. Having prepared the matter in manuscript, it is necessary to get the illustrations ready. For this purpose the various articles to be portrayed must be photographed. Of course, where they are large and heavy, as in the case of machinery, the photographer must attend the factory and take the pictures there, and every facility should be given him in the way of light, backgrounds, and so on, for the success of the price list from the selling point of view will depend to a certain extent on the pictures of the articles it is bringing to the trader's notice. If, on the other hand, the articles are small, as when they are food packages, boxes of soap, bottles of wine, and so on, it is much better to let the photographer have them at his studio, where he always has greater facilities for taking pictures than any ordinary factory can provide.

As so much depends on the pictures, only a really first-class photographer should be engaged. The pictures need taking only once, and a little extra cost does not amount to much when spread over thirty or forty thousand copies of the catalogue. The photographs, being taken satisfactorily, are not quite ready for the blockmaker. It is here that so many pictures that might be excellent are spoilt, just as the historic ship was spoilt for lack of a ha'p'orth of tar. To get the best results in the blocks for printing it is necessary that the photographs—that is, the prints—should be touched up by an expert retoucher. In many cases—in most cases, in fact—it is best to have the backgrounds painted right out, so as to leave the object standing right out before the observer, with no surrounding objects to distract attention. Special points can be emphasised; and it is astonishing how much a skilful retoucher can paint out or paint in on the print which will appear as part of the photograph when the block is made and printed.

The question of the photographs is very important, and must be treated as a whole, for it is quite possible for each individual picture in a catalogue to be excellent, but for the whole to give an odd and scrappy and disconnected appearance to the book. For example, if a number of boxes are to be portrayed on the different pages, then these should all be photographed at the same angle. The main label must, of course, be the principal feature that stands out, whether it be the top or the side of the box, but the photograph should not be a full front view; a little of the other sides of the box should also show. All the pictures being thus taken at one angle, there is a harmonious feeling that appeals to the person looking through the list, although possibly he may not be conscious of what gives the unity. Nothing can be more incongruous than to have a number of boxes or packages, more or less similar in shape and appearance, printed on the same or opposite pages in a list, some showing a little of the right-hand side,

some a little of the left, some the top, and some the bottom, and so on.

Another point must be mentioned in this connection. If the objects to be photographed are round, as in the case of tins and bottles, then it is important to get all the label into the photograph, so that it can be read easily. Very often a commodity may be packed in receptacles of several sizes; and while one bottle or tin may be so small in diameter that the label goes too far round on either side for the name to come out completely in a photograph, a larger size with a greater diameter to the receptacle may take the label so that the photograph will get it all in clearly. In selecting a picture to illustrate the line, the size bottle or tin that looks best in the photograph should be chosen. This seems a simple matter, but it is astonishing in how many thousands of catalogues it is overlooked or ignored.

Still one more point in connection with pictures illustrating a price list needs a reference, and this is the size of the blocks. It is, of course, always wise to give the pictures as large as possible. Small blocks are apt to look mean, and make the object they illustrate insignificant. But while fairly large blocks should be the rule, it is not wise to make every block as large as space will allow. Some sort of relation must be maintained among the various articles portrayed. Thus while a one-pound tin of coffee and a seven-pound tin cannot be given to scale, yet the seven-pound tin should appear somewhat larger in the list than the one-pound. A one-pound tin appearing in the picture twice as great as the seven-pound tin would make the catalogue ridiculous. On the other hand, the same sort of relation as to the size need not be maintained in regard to entirely different lines appearing in different parts of the book. Common sense should be the great guide, although an examination of some hundreds of price lists does not suggest that it has come much into play in this matter of the relative sizes of blocks.

Size and Shape. Before actually making the blocks we must decide upon the size and shape the catalogue is to be, and this is, of course, guided largely by the amount of matter that has to be got into the list and the nature of the pictures. While for the purpose of showing machinery or other objects as well as possible it is an advantage to have a large page, so as to get the blocks big, it is unwise to have the page so large as to be ungainly. The whole point of a trade catalogue is to keep it in the hands of the dealer; and if the size is too large it is likely to be folded and get pushed out of sight. It is better, therefore, in a general way, to conform to the custom of the trade, and make the list more or less in size and shape like those of other manufacturers in the same line of business. Of course, there are pioneers even in the production of trade lists and catalogues, men who strike out in new shapes and sizes, but, as a rule, in these days the best form has already been arrived at, and there must not be too much striving after novelty.

Another consideration has to do with the printer and papermaker. Paper is manufactured in sheets of certain stock sizes, and these fold up into eights, twelves, and so on, of certain recognised page size. It is always costly, therefore, to depart too much from stock sizes, as the paper has to be folded and cut to considerable waste. Then the number of pages should, if possible, be kept in multiples of sixteen for a large list, of eight for a smaller list, and of four for a still smaller list. If the cover is not being printed on a separate paper, but on the same paper as the body of the list, then it should form a part of one of the sixteens. Thus the list will consist of a four-page cover and twelve, twenty-eight, forty-four, or sixty, etc., pages. If, on the other hand, the cover is on a separate paper, coloured or white, then the body of the list would have sixteen, thirty-two, forty-eight, sixty-four, etc., pages, independent of the cover.

The matter and the pictures that are to go in being ready, the best size of page for the list and the exact number of pages must be decided; and it is always well in this matter to confer with the printer. This matter being settled, a selection of types for the headings, paragraphs, prices, etc., must next be made; and before going on with all the list it is advisable to get a specimen page set up. In actual practice, a type that looks well in the type-book or in another advertisement may not prove so suitable as was supposed; and by having one specimen page set up it is easy to make alterations until something that commends itself as typographically satisfactory is obtained. The list is to be printed in large quanitties, it is to be revised from time to time, but kept in the same form for the sake of continuity, and it is therefore worth while in the beginning to take a little trouble to get it as nearly perfect as possible for the object it is to fulfil.

Filling Blank Pages. It very often happens that after getting all the matter set up and arranged in page form there are one or more pages out of the sixteen that are left with no matter for them. Incredible as it may seem, some manufacturers actually issue their catalogues with these pages empty. Could anything be more futile? Here is an opportunity, at practically no cost at all, to tell the story of the goods, to provide some really good selling talk, to give pictures showing the equipment of the factory, and yet the opportunity is often missed.

The advertising man will take full advantage of such a chance. If the factory is an engineering works, pictures and descriptions of the up-to-date plant should be given; if the factory turns out food products, the cleanliness should be emphasised and illustrated, reproductions being given of any certificates of purity that have been obtained from official and authoritatvie sources. In all cases, extracts in praise of the factory from responsible newspapers and journals, testimonials from well-known customers, and similar recommendations should be reproduced.

The Cover. The question of the cover is one to which some time and thought should be given. If the paper is to be different from and better than that of the body of the list, it is as a general rule an advantage to select a coloured paper. Where, however, half-tone or even line blocks are to appear on this, the colour should be a light one, or the blocks will not show up to advantage. Where a calendered paper is used, if white be selected, this begins to look shabby and old directly it is handled, as every mark of the fingers shows up. No hard-and-fast rule, however, can be laid down; each case must be treated on its merits.

Another question which has to be decided in connection with the cover is whether it is to be printed in one, two, or three colours. Here it may be said that save in exceptional circumstances it is never worth while to go to the expense of three-colour blocks for the cover of a trade catalogue,

attractive as such may be for a list that is being issued to the general public. It is sometimes worth while to print a trade list in two colours, but usually this is an unnecessary expense, as a two-colour effect can always be obtained by using a coloured ink on a coloured paper. Even for trade catalogues the cover design should not be left to the tender mercies of the printer. He will make up a more or less elaborate border or design to fill the page, but it will always smack of the mechanical, being composed of stock ornaments pieced together. For two or three guineas a very good, plain design for a catalogue may be obtained from a competent artist, and this will serve for years. In getting a design that is to last, see that such wording as is likely to be changed from time to time—date, telephone number, and so on—is not part of the design, but can be let into boxes or panels drawn by the artist as part of the general scheme.

Reading the Proofs. Great care must be taken in reading the proofs of a price list, and every figure should be checked in the final proofs just as they go to press, a duplicate being kept with all the corrections in the printer's copy, so that in the event of any mistake the responsibility can be fixed. The advertising manager should see that the proofs are placed before every member of the staff who has any concern with the facts set forth; that is, the official responsible for the stock should see that no lines appear in the list that are out of stock and likely to remain out of stock; the official responsible for fixing the prices of goods should see the prices, and so on. The importance of this can be realised when it is understood how serious a matter it may be for a firm if an offer of goods is scattered broadcast through the trade with a wrong price on the offer, or when no stocks are available.

If it is desired to draw special attention, in any particular issue of a catalogue, to some one line or item, this may be done by printing a line on the page in red, or by inserting a loose sheet with the necessary particulars. Of course, these methods involve extra cost, but the cost is usually worth while in such cases. Wherever possible, the price list should contain an easily detachable order-form, with everything tabulated as far as possible, so that all a would-be customer has to do is to fill in a figure stating the quantity he requires. It may be argued that anyone who is requiring goods will order them, whether there be a form handy or not, but all experience goes to show that the more you can help a man to give an order, the more likely he is to give it; and providing an order-form, so that the minimum of writing is required on the part of the customer, is certainly helping the buyer.

Making the Catalogue Valuable. There are various little devices by which a price list may be made additionally useful to its recipient. If it is at all thick, the various sections may be thumb-indexed in some such way as that mentioned below under the description of retail lists. Then it is of supreme importance that the dealer should keep the list at hand, so that he can refer to it easily whenever he wishes to do so, and for this purpose it is wise to eyelet the top corner and have a cord loop so that the list can be hung on a nail. In this way it will not only be handy, but its mere appearance hanging on the nail will be a continual advertisement to all who see it.

In some trades it is worth while to devote a page or more of the list to general information which is constantly in demand but is difficult to remember. Various weights and measures used in the trade, references to certain laws affecting the trade, hints, and so on, make the list valuable, and it is to the dealer's interest to keep it handy for this information. In this way you are getting him familiar with handling your list, which is one of the steps towards making him a regular customer. Along the outside of the cover in its greatest length can be printed a rule, of six inches or more, marked off into eighths, or with any other particular measurements commonly used in the trade.

Loose-leaf Catalogues. The latest development in the production of trade catalogues is that adopted by some large manufacturers and importers of special patented machinery, who issue loose-leaf catalogues which they lend instead of give to probable buyers from whom they get inquiries. The cover is in the form of one of the many patent files on the market, and any sheet can be easily removed or added to the list at any particular place. The advantage in this is that the lists are kept up to date, but, of course, such a system can be adopted only where the list is lent.

Distributing the Lists. Having produced a serviceable and attractive price list, it remains to distribute it, so that it gets into the hands of the people for whom it is intended. The usual method is, of course, to do this by post, and envelopes should always be used. A list enclosed in an ordinary wrapper with open ends is so obviously printed advertising matter that it stands far more chance of being thrown away unopened than of being taken from its wrapper and perused. For this reason envelopes should be used. They should be of fair quality, and it is better to have no printed matter—possibly not even the name of the firm issuing the catalogue—upon the envelope. Curiosity will then almost certainly ensure the list being taken out and looked at.

In posting lists, always use adhesive stamps instead of sending the packages to a post-office in bulk to be franked. The franking process—in which no adhesive stamp is used, but merely the word "Paid" in a circle is impressed on the wrappers—renders each package so obviously one of thousands that the recipient is quite likely to throw it away unexamined. In posting catalogues in large quantities it is, of course, unnecessary to use penny stamps. Halfpenny stamps are quite sufficient, the flap of the envelope being turned in.

Export and Special Lists. Firms that are doing a big export trade usually produce one or more export lists. One list, for example, may be for America, another for South Africa, and another for Australasia. In such cases, it is well, for the sake of distinction and in order to avoid confusion, to use a different coloured paper for each particular list. Thus pale pink might be used for the home list, buff for the American, blue for the South African, and green for the Australasian. The advantage of this is that the same design may then be common to all, and yet the distinctiveness remain.

For the Continental countries and for South America the lists would probably have to be in foreign languages, and it is quite usual for manufacturers and merchants to combine the principal languages into one list. Thus, the particulars of each article might be given in English, and then underneath in four columns, in smaller type, the matter might be repeated, translated into French, Spanish, Portuguese, and German. If a South

American trade is being catered for, it is necessary to use both Spanish and Portuguese, for not only is Portuguese spoken in Brazil and Spanish in the other countries, but there is much jealousy in regard to the language question among the South Americans; and even if a Brazilian could understand a list in Spanish, he would resent the fact that it was not in Portuguese.

These translations have to be made very carefully, and it is not enough to leave the work to one of the many translation bureaus that are found in all our large cities. Their idioms are often very faulty, they are somewhat hazy on trade and technical terms, and the result of their efforts should be checked by someone actually in the trade who understands the language in question. In food catalogues, all English measurements given in directions need to be not simply translated, but changed into the metric system—pints into litres, and so on. This question of translating the matter of a catalogue into the language of the country to which it is being sent is very important, and no firm that intends to do business should omit it. It is by our failure to make ourselves and our products understood in this way that we British have lost so much trade in the past to Germany, who, wherever she has gone, has been wise enough to advertise to the buyers in their own language. The prices, too, should always be in the money of the foreign country and not in English coinage, which the buyer is not at all likely to comprehend.

Other points worth remembering when preparing a trade catalogue will be found set forth in the particulars, below, of retail lists. As already explained, although they are entirely different propositions, there is much that is common to both kinds.

Retail Catalogues. Retail catalogues vary tremendously in size and appearance, according to the firms which issue them. The preparation of a large catalogue such as the great department stores send out to their customers will be described, and it will be understood that smaller establishments issue similar lists, but on a smaller scale. The great store must get into its list practically everything that the public uses, and the majority of these things must be illustrated. The blocks are, in the majority of cases, stock-blocks, some, such as brushes, tools, dish-covers, etc., being supplied by the firms that make and sell electros to printers; and others, such as proprietary articles made by special manufacturers, being supplied by the manufacturers themselves. The customers of these great stores are in the habit of doing all their shopping at their favourite establishment personally or by post or telephone, and for this reason it is essential that everything from a pin to a motor-car should be in the list.

Arranging the Items. The great stores and all similar establishments are arranged in departments, and it is the custom—a custom proved to be the most convenient by long usage—to arrange the matter in the lists in a similar way. The particular order in which the departments are given in the list is not essential, but it is customary for the grocery department to stand first, although this is not invariable. Whatever particular arrangement, however, is decided upon, it is wise to place the essentially household departments close together in the early part of the book—grocery, ironmongery, etc.; and the clothing sections, hosiery, tailoring, dressmaking, lingerie, drapery, etc., should also follow one another.

The arrangement of departments having been settled, the next point to be decided is the order of the various items in each department. No invariable rule can be followed; for while grocery with its hundreds, if not thousands, of lines is best arranged alphabetically, such a system cannot so well be followed in jewellery, where page after page will deal with articles of the same kind, like clocks, watches, etc., the alphabetical idea being thereby lost. As far as possible, however, the alphabetical arrangement should be followed, but any necessary departures are met by the copious index, which will enable a searcher to find without delay any particular line he or she wants.

Of course, there are many headings that will come in a particular department, such as the grocery, which will themselves have a large list of sub-headings indented under them. Take, for instance, biscuits. This will come in its proper place under B, and then there will be the various kinds of biscuits, the whole list being indented one or two ems. In some stores' catalogues, as many as 240 different kinds of biscuits are mentioned by name. This is only an instance, but there are many such. Hence it is necessary to give the main entries in a black type, so that these sub-lists of varieties can be distinguished by printing them in a smaller and lighter type for distinction. In the case of the heading "Biscuits," it is well to give under it only the varieties of biscuits for people. Dogs' biscuits should be a separate main heading, thus: "Biscuits, Dogs'. See Dogs' Biscuits." Common sense must be used in such matters when compiling the lists.

Preparing the Matter. From the nature of things in a catalogue of this kind there can be no long description of the majority of the items. In fact, in most cases there will be simply a picture, with two or three lines of descriptive matter, a list of sizes and prices, and a reference number which can be quoted in ordering. Special lines, new inventions, and so on will, however, be described more fully. A combined billiard and dining table on some new or unusual plan should have its mechanism and advantages set out fairly fully; furniture such as bookcases, pianos, gramophones, etc., needs more than the average amount of letterpress, as it is necessary to give a fairly full specification—style, wood, size, pattern, and so on. The grocery department will, of course, have fewer pictures than most of the other sections, although here facsimiles of the packages of proprietary articles will brighten up the pages and at the same time serve a very useful purpose described below.

Making up. Making up a list of this character is a big job; and while a good deal may have to be left to the printer, it is necessary for the advertisement manager or his deputy who is editing the list to indicate as far as possible the arrangement desired. In fact, the best method of obtaining a satisfactory result is to have proofs of all the blocks and all the cutlines and matter, and to paste them up page by page. After the pages have been made up, alterations in the positions of blocks and so on can be effected, but as little as possible of this kind of thing should be carried out, as it all means extra expense for corrections. A little more time spent on the make-up will obviate a great deal of this.

General Matter. In addition to the main catalogue in which the various articles for sale are described, there will be a number of pages of general matter, such, for example, as an almanac, a list of suburbs to which deliveries are made by motor-car,

and the days of delivery; regulations as to packing-cases and empties; plans of the various floors at the establishment, so that customers may be familiar with the topography when they visit the place; a list of departments; map of the district, with the position of the establishment clearly marked; a list of 'bus, tram, and train routes, nearest stations on various lines, and so on. In addition, there will be a title page; and at this point it may be mentioned that in sending out the lists to customers it is well to insert a few loose order-forms.

The Index. Next comes the index, and this must be very carefully compiled, and still more carefully checked, for nothing is so fatal to business as for a would-be customer to look up in the index a certain item she is in need of, and then, when she turns to the page indicated, to fail to find the article upon it. Of course, this means that before the index can be begun the pagination of the body of the book must be definitely settled. Many items may need a double entry, some proprietary articles, for instance, which would be given under the manufacturer's name where it was a household word, and also under the particular article in question. The type need not be large; and the page—if it is quarto size, the usual size for large lists—can be divided into four, five, or six columns.

Different Coloured Papers. It is a great advantage if the index and any other special sections to which it is desired to draw attention, or which it is wished to distinguish from the main body of the book, be printed on a coloured paper. Where an export section is given this could be printed on one colour and placed at the end, while the index could be printed on paper of another colour, and should always be placed at the beginning of the book.

At every opening of the book, the head of the left-hand page should have printed in bold, readable type—though not so large or black as to be ugly—the full name of the firm; and the top of the right-hand page should have the name of the department in which the goods described on the page are sold.

Thumb-indexing and Binding. The American system of thumb-indexing is a splendid one for large catalogues of this kind; and as it makes reference easy and therefore assists the customer, it must be a selling asset that is worth using. The various sections of the catalogue can be thumb-indexed in the same way as the books of a student's Bible are, and the alphabetical index itself may be divided at the margin in the same way.

Where a catalogue is going to run to a thousand pages or more, the binding should certainly be something more substantial and lasting than paper or cardboard. Such a book is an expensive production; it is interesting enough for a person to keep, but a flimsy cover will cause the corners of the pages to be dog-eared in no time. The book then looks very untidy, and is pretty certain, very soon, to be thrown away. If, on the other hand, the catalogue is bound in a good, sound, stiff cloth cover, the book looks far more important, its life is much longer, and it is a great deal more serviceable.

Manufacturers' Advertisements. The cost of turning out these very large catalogues such as the big department stores issue is enormous; and as they have to be given away free, the question of finding some source of revenue which shall help to pay the cost is an important one. Such a source of revenue does exist, and a very large sum is realised by letting space in the lists to manufacturers of proprietary articles for the purpose of advertising their specialities. These advertisements take a variety of forms. In the first place, there are a number of pages given up entirely to advertisements, and these are let as whole pages, halves, quarters, eighths, and in some cases sixteenths. The pages are sometimes distributed through the book singly or in groups, and sometimes they are grouped together at the beginning or end of the list. This latter arrangement, however, is not so satisfactory to the advertisers; and as in a matter of this kind it is always well that both sides should be mutually benefited, it will be better to distribute the pages instead of bunching them in one place.

Another source of advertisement revenue is found in the body of the list. Where proprietary articles are mentioned—and of course if the list is to serve its purpose and be complete it must mention them—a charge can be made for putting the manufacturer's name in black type, or at any rate in heavier type than is usually adopted for the various lines of goods. It will be found that in most cases the manufacturers will be willing to pay for such an advantage, or, rather, to be saved from the disadvantage of not appearing thus prominently when their rivals are adopting the plan. Many of the manufacturers who take space in the advertising pages and pay for the setting of their names in the body of the work in a bolder type will make it a condition that their advertisements shall face the quotations of their goods. This is a reason for distributing the advertisement pages through the book, as thereby an opportunity is given for meeting the wishes of the manufacturers in this respect.

An Alternative Plan. In order to give a greater uniformity to the catalogue, and to avoid the collection of advertisement pages at the beginning or end, or the dividing of the body of the work by such pages being distributed throughout, there is another plan which gives an excellent result, and is being adopted by some large stores. Instead of having whole pages given up to the manufacturers' announcements, a certain space—say, a couple of inches—is set apart at the foot of each page, and these spaces are let out at a fixed rate to the advertisers. Certain restrictions can be made as to the kind of blocks or type which shall be used, and this will prevent heavy and ugly blocks spoiling the general effect and distracting attention too much from the blocks illustrating the items in the list itself.

In many cases, second, third, and fourth covers can be used for advertisements at higher prices than the pages or spaces inside; and if the cover is cloth, or is printed in two or more colours, still higher rates can be obtained. Advertisers' own insets, too, can be taken, and either inserted loose or bound in when the body of the work is bound up. A certain number of these from the best manufacturers should be sought, as they are usually in colour, well printed on stiff paper, and form an additional attraction to the list. Carpet firms, china firms, soap and scent makers, playing-card printers, fountain-pen makers, and cigar firms are among those who prepare some very fine and attractive insets for this purpose.

The Cover. The importance of binding a big catalogue in a substantial cover which shall preserve the book in a healthy and presentable condition for the term of its natural life has already been referred to, but a word or two may here be said about the colour and design of the cover itself. These should certainly be attractive, but this quality must not be allowed to interfere with the serviceable character of the work. In colour, for

instance, we may select a cloth that is bright, but not so light as to be easily soiled. A grubby-looking catalogue is apt to convey an impression to the mind of the beholder which connects up the firm issuing the list with its appearance. A fairly dark-coloured cloth with a gold-blocked design is perhaps the best that can be selected.

In this design, on both the front of the book and on its back, the name of the firm or store must be the most prominent wording. If the building is a fine one, then a representation of it will enhance the appearance of the cover, and will familiarise the customer with it, so that when she visits the place, even for the first time, it will not seem to her strange. If, on the other hand, a card cover is to be used, the design should be a very attractive one—in colour if possible. On the cover should always appear the address of the firm, the telephone number, and telegraphic address. These should, of course, be repeated on the title page and at various places inside the book; and if they can be given, say, at the foot of every page right through the catalogue the convenience to the customer will be greatly increased.

Departmental Lists. Some large stores, instead of using one large and complete list of almost ungainly size, publish, at intervals of a week, month, or quarter, a series of departmental lists, one devoted to grocery, another to drapery, and so on. Each of these is, of course, of pamphlet size, with paper cover, and some are issued much more frequently than others. This method has its advantages, one of which is that it is less expensive than the big annual list system. Further, when prices are advancing, or otherwise, it enables the customer to have at hand at all times a list with current prices. But in the majority of the homes to which a list goes it is far less likely to be preserved if in the form of a pamphlet or series of pamphlets than if it is in the form of a large, well-bound, and well-illustrated volume of 1500 pages. The latter will probably have some definite place reserved for it in the home, and so will always be at hand when it is wanted. Thus there will be regular publicity all the year round. Anyway, if the departmental pamphlet system is adopted, every list sent out should, if possible, be eyeleted and corded, so that there may be an inducement for the housewife to hang it up in the kitchen for ready reference.

Local Lists. Where a firm has a number of establishments in different countries, as for instance in London, Edinburgh, Dublin, Toronto, Sydney, and so on, it is often the practice to issue local lists. The body of all these will be more or less alike, but the prices are arranged for each locality. In such cases it is best to use different-coloured covers for the various lists for distinctiveness, just as the manufacturer uses various shades for his home and export lists. On every local list of this kind all the addresses of the firm should be given in more places than one, so that people may take note of the various addresses if they are about to travel.

Lists for Small Establishments. The retail catalogue thus described at length is, of course, one of considerable size, such as only a great department store could afford to issue. But thousands of smaller retailers, right down to the moderate-sized grocer's shop in a town suburb, issue annual and half-yearly lists. These are, of course, little more than pamphlets. They consist of anything from 32 to 96 or 128 pages, and are prepared on the same lines as their more pretentious brethren. Octavo is the most usual size, but it is now getting the fashion to produce them in a long, panel shape, which is very convenient. They are usually more or less illustrated, should be well indexed, and certainly eyeleted and corded for hanging up.

Lists of this size are not usually arranged in departments, as, being for grocers' shops, chemists', or establishments of practically one trade, they have not the many departments of a great store. The method generally followed, therefore, is to put the whole list in alphabetical order from beginning to end.

It may be asked how a small tradesman can afford to issue a list, seeing that the expense of printing is so large. The answer is that he recoups himself for a very large portion of his outlay by securing advertisements from the firms from whom he buys his goods. They have a system of paying for these advertisements by making an allowance—1¼ or 2½ per cent.—on the total amount of business done with them during the twelvemonth; and thus, if the shopkeeper is doing a progressive trade, his list produces a progressive revenue which may more than cover the cost of printing and distribution.

The percentage arrangement is a much more satisfactory plan for all parties than the charging of a fixed rate per page. The shopkeeper, as he does more business with a manufacturer, finds his rate per page automatically increasing without any bother or effort on his part, and the manufacturer has no objection to paying a constantly increasing price for his announcement if a progressive rate means that he is doing a constantly increasing business.

Every retail list of this kind should contain one or two order-forms for the use of the customer into whose hands it falls.

Distributing Catalogues. Having produced an issue of a retail catalogue or price list, the all-important question now is, how shall it be distributed? First of all, we must know to whom we are going to send it, and secondly by what means we are going to get it into their hands. In the case of the large and expensive catalogues issued by the great stores, these will, of course, go only to customers of some standing. They are too costly to distribute broadcast, and even where applications are made for them such applications should be well sifted. There are always a number of people who are ready to obtain something for nothing, and among a certain class of people who are essentially non-buyers these great illustrated catalogues seem to exercise a strange fascination: they like to possess them. Others, again, are known to ask for such volumes in order that they may provide picture-books for their small children. Needless to remark, all such applicants for catalogues should be weeded right out, for lists sent to such people are absolutely non-productive. Only regular customers should receive the large bound volumes. A list of all persons to whom they are sent should be kept and revised each year. They should in every case be addressed to the customer by name, carefully packed so as to avoid damage, and despatched by carrier, as soon as possible after they are ready.

In the case of the smaller departmental lists, a wider distribution may be thought advisable. Every customer should receive a copy, whether he or she buys much or little, and in this case, of course, the lists will be forwarded by book-post.

The small retailer who issues a list will probably send copies round by hand to all his customers, and he may find it worth while to send also to people who are not customers, or, at any rate, not regular

customers. In selecting these he will take only the best roads, striking out any people who are notoriously bad payers, or for other reasons undesirable as customers. The remarks about posting given above under trade lists apply also to retail catalogues if they should be posted. They should always be sent in envelopes and stamped with adhesive stamps; and it is much better in such cases for the envelopes to be addressed by hand than typewritten, as the typed envelope to the lady of a house is more suggestive of circulars than a handwritten envelope. In many ways it is better for the small retailer to post his lists, as they are then quite certain to come into the hands of the lady of the house, whereas if they are delivered by hand they may never get beyond the servants.

Of the third class of catalogues referred to above —namely, those that are intended for the trade, but are so prepared that they may be shown to the public—little need be said. As mentioned, the best examples are those issued by the makers of gas and electric-light fittings. Builders and others show these to their clients, so that the latter may pick their fittings. The lists are compiled in just the same way as ordinary illustrated trade catalogues, but the prices given are such as the public will pay, the builder or other dealer getting a substantial discount, which is his gross profit.

The Standard Export Catalogues. Recently a new idea in export catalogues has found much favour with manufacturers. This is the Standard Catalogue system, which was initiated in 1910, and has now passed far beyond the experimental stage. The idea is a simple and valuable one, and is being carrried out most admirably by the Standard Catalogue Publishing Company, who have already issued about sixty thousand catalogues. Hitherto the overseas buyer has had to rely for his information, when purchasing, upon a heterogeneous mass of price lists of all sizes and shapes and styles. The mere multiplicity of style has meant that there was no adequate method of filing these, or of referring to them when necessary. The Standard Catalogue is a system of bringing all the essential information of all the manufacturers' individual lists together into one volume, or series of volumes, uniform in size and style, completely indexed, and available for reference at a moment's notice.

The great Standard Catalogue is divided into series: hardware and earthenware; cutlery, plate, and jewellery; textiles; groceries and provisions; drugs and toilet requisites; printing, stationery, and fancy goods; sports and toys; furniture and musical instruments; motor-cars, cycles, and accessories; building materials; and engineering. Some of these series are already issued, and have run into two editions, 1400 of the leading manufacturers being represented in two trades alone. Other series are in course of preparation; and as it progresses the work is, in the business world, becoming in fact what it is in name—the British Standard Export Catalogue. Manufacturers take so many pages, supplying matter and blocks, as they would for lists of their own. The matter is translated into French and Spanish, so that being in these two languages, and in English, it is practically available for most parts of the world.

The volumes are large, handsome books, strongly and handsomely bound, with the various sections thumb-indexed, and a copious index to make ready reference easy. A certain charge per page is made to the manufacturer, and the producers guarantee to distribute complete copies of the great work among the biggest and best buyers throughout the world, so that not only is the manufacturer able to issue an export catalogue at much less cost than if he did it himself, but he is absolutely certain of getting it into the hands of all the best buyers throughout the world, thereby securing all the advantages which may be possessed by his keenest competitors.

For the purpose of distributing the great Standard Catalogue, the producers have compiled, with the aid of the best official and non-official sources, probably the most useful list of export buyers that has ever been made up. The countries covered by the British Standard Export Catalogue include Canada, South Africa, Egypt, United States, France, Belgium, Russia, South America, Australia, New Zealand, East Indies, West Indies, Spain, Norway, Sweden, China, Japan, India, Straits Settlements, Malay States, Portugal, and Italy. Special attention is being given to those markets hitherto largely exploited by Germany.

Everything has been most carefully thought out. Each page, section, and volume of the catalogue has a three-letter cypher word to itself, so that any foreign buyer or manufacturer can cable a reference to any particular line at a minimum cost. Already with the series issued the position of the Standard Catalogue is so high that no manufacturer or advertiser who desires to do an export trade can afford to be out of its pages.

The House Magazine. A comparatively new form of advertising that is coming more and more into favour in England is the house magazine, and, as it is analogous to the catalogue and price list, it may be referred to here. It is a magazine issued periodically by a firm and sent to its customers and probable customers, in order to keep the name of the firm before them. It is a valuable medium for those firms who confine themselves to one or two particular commodities which are more or less steady in price, and have no reason for issuing price lists regularly. In America the idea of the house organ has been very extensively adopted, and has proved highly successful. It is from America that we have borrowed the idea.

While the main and primary object of the publication is to advertise the firm and its goods, it must not be a mere collection of advertisements cast into the form of a magazine. It must be distinctly a magazine in the true sense, with articles of general interest, and if the firm is a wholesale one these articles should be more or less connected with the business in which the firm is engaged. Thus, an engineering firm will find in recent achievements and discoveries a wealth of matter from which interesting, up-to-date articles can be compiled, and, of course, these should be well illustrated. The magazine should be nicely printed on good paper, and should have an attractive cover printed in two colours.

There should, of course, be a number of definite advertising pages, among these being the second, third, and fourth pages of the cover, and possibly some pages at the end of the body of the magazine could be given up to the same purpose. But, in addition, there are great possibilities in the articles themselves. A new machine or product that has really interesting points about it, especially if they have a bearing on modern scientific discovery or industrial and commercial development, is well worth a special article; and where anything technical and difficult can be illustrated by a picturesque and lucid diagram, explained in a popular style, the interest of the reader will certainly be arrested and held. Importance of Machinery in Woodworking. Woodworking Economy. Sawmill Arrangements. The Principal Machines.

THE MODERN SAWMILL

PRACTICALLY all the industries of the world are indebted more or less to woodworking machinery. The hand methods of the carpenter or joiner are not applicable to manufacturing in quantity, and machinery, therefore, supplants the human element, with resulting advantages from the points of view both of output and of accuracy. The classes of operations include those of cutting, scraping, and abrading, by which the cutting up and finishing of wood are effected. Both plane and curved faces are treated. The division of timber is carried out with saws in the first place, termed *breaking down* or *breaking up*, followed by *re-sawing*, which cuts it into smaller pieces of various shapes. These are further treated on machines which plane, mould, mortise, tenon, carve, dovetail, turn, bore, smooth, and polish as required, some of the operations being obviously unnecessary on certain work, while on other classes every one may be carried out.

There are five classes of machines used for converting logs into deals, flitches, planks, and boards. They are the *frame* saws, the *horizontal reciprocating* saws, the *horizontal band* saws, the *vertical band*, and the *circular* saws.

A Railway Sawmill. An excellent idea of the appearance of a sawmill may be gained from the photograph [1], taken in the carriage and waggon department of the Midland Railway Company's works at Derby, and shown here by the courtesy of the superintendent of that department, D. Bain, Esq. A large quantity of timber is used by the company in connection with the production of carriages and waggons, and carts, drays, barrows, etc., including repairs. The average annual output is 5500 new waggons and 200 carriages. A gantry is provided outside the mill, carrying two overhead travelling cranes, which pick the logs off the railway trucks, and set them on a cross-cut saw which cuts them up into suitable lengths. The mill, which has a floor space of about 10,000 square yards and is driven by engines developing about 800 i.h.p., has a cellar in which the shafting and belting are placed. An overhead traveller is seen in the illustration, holding a short balk, and various circular-saw benches and frame-saws are visible. The aim in the design of the mill is to keep the timber moving in a straight line as much as possible from end to end, passing on the way to machines that re-saw, plane, mortise, and tenon.

Figure 2 represents a rather different lay-out, and shows the interior of the sawmill of Messrs. Marshall, Sons & Co. The machine in the foreground is a horizontal band-saw, and a trolley track runs the length of the building for the easy conveyance of logs and sawn timber. The view illustrates the system of roof-lighting and the loftiness of the buildings.

Log-sawing Machines. The first operation upon logs coming into a sawmill is to part them off into suitable lengths for cutting down into boards, etc., unless it should happen that the whole length of a log is wanted. A direct steam-driven machine (Haigh, Gruban & Co., Oldham) is shown in elevation and plan in 5, with a log in position. The steam cylinder, A, by means of its piston reciprocates the piston-rod, and the saw-blade, B, attached thereto, the teeth being set to cut on the inward stroke. The reversal of the piston is not effected by ordinary valve gear, but steam is admitted and cut off by a valve, C, operated through the medium of the guide, D, which, sliding on the guide-bars cottered to the front cylinder cover, turns a flat twisted strip, E, as it moves, and causes the latter to turn a lever, alternately opening and closing the valve. The strip, E, turns easily by its round ends in bearing holes. The cylinder, A, is suspended by spigots in trunnion bearings on the baseplate, and a quadrant bolted on the rear has worm teeth upon it, engaging in a worm on a vertical shaft turned by the handwheel, F. This mechanism enables the attendant to raise or depress the saw-blade and to feed it downwards through the log. The latter is tied to the machine by two long rods pivoted to the baseplate, and having spiked ends, which are hammered into the log. The reason for making the saw cut on the inward stroke is that it is thus put in tension, and does not buckle as it would if pushed outwards. It may be mentioned that this method of steam-driving was originally devised by Messrs. Ransoms, of Newark-on-Trent.

Felling Trees by Sawing. An adaptation of this mechanism is made for tree-felling by turning the blade on its side, and employing a horizontal quadrant guide to let it slew around as the tree is cut through. A wedge is driven into the saw-cut after the blade, in order to keep the kerf open and prevent excessive friction on the blade. When these machines are portable, the steam is conveyed by a flexible hose from the boiler, which may serve several fellers and cross-cutters. Trees 3 ft. or 4 ft. in diameter can be felled in five or six minutes. Some large tree-fellers are mounted on wheels like a gun. A hydraulic jack, with a concave-headed ram, is employed to raise trees which have been felled and are being cross-cut, to prevent the blade from being pinched in the kerf; wedges are sometimes used instead.

Circular saws are not used so much as these reciprocating blades, partly because of their greater cost and the limitation in the diameter of log that can be cut through, but they work more rapidly.

Breaking-down Machines. Logs are divided longitudinally into portions of various sizes, known under different names, and the operation may be effected on a single machine or in two successive ones. Boards may be cut direct from the log, or the latter may be first broken down into deals (in the case of pine), flitches, or planks, which are further treated on other machines.

Log saws are those which begin work upon the logs and balks; *deal* and *flitch frames* are used for re-sawing the deals and flitches into boards. The first class of saw may be either a *log frame* or *timber frame*, a *reciprocating saw* or single-blade *board-cutter*, or a band-saw. The deal and flitch frames are of reciprocating type. Circular saws are

also employed for breaking down logs. Each kind has its advantages and disadvantages, which are discussed as the different types are illustrated.

Log Frames. The log or timber frames comprise a vertical *housing* through which the logs pass, and are divided by a number of saw-blades moving up and down. The frame-saw is the oldest type of machine, and is employed most extensively, though it is slower in operation than later machines which are coming rapidly into favour. The advantage is that logs may be divided accurately into boards, etc., without re-sawing, one pass sufficing for the operation. Means are provided for feeding the logs through at varying rates. The roller feed is suitable for straight, even timber, on which the rollers can get a good bite all along ; the rack feed is used for crooked, uneven logs, or on those which are frozen, and would not be gripped easily by rollers. The advantage of the roller feed is that the logs can be passed through quickly in succession, and there are no carriages to be run back for starting fresh logs, as in the rack feed, the result being a considerable saving in time.

The rack feed is more positive, and is better for hard woods, on which rollers are liable to slip under the strain of feeding. The rollers and the carriages are actuated by a feed motion derived from the driving mechanism of the machine, arranged so that the feed is imparted just before or on the down stroke of the saws, which, as they cut only in one direction, cannot have a continuous feed, as band or circular saws may. The saws, which, to work efficiently, must be strained very tightly, are fastened in a *saw frame* or *working frame*, or *swing frame*, or *saw gate*, with cotters and *buckles*, and the frame slides up and down between guides which are adjustable to take up slackness.

There may be only one, two, three, or four saws for opening out a log into thick pieces, which may or may not be re-sawn, or 40 to 50 blades can be used for cutting a log into thin boards. A frame must be strong enough to resist bulging out sideways when all the saws are cottered or *hammered up* in it, otherwise it will bind in its guides, although many machines embody provision for a little latitude in this way, so that if the frame is bulged it will still slide freely.

Log Frame with Rack Feed. Taking up the details of log frames, we first give side and front elevations [3] of a 24-in. frame, with rack feed, by Messrs. Haigh, Gruban & Co. The upright cored frame, A, which is seen to be well spread out, in the side view, receives all the working portions, and ensures rigidity and freedom from vibration. The fast-and-loose pulleys, B, drive the crank-shaft, C, the heavy flywheel on the other end of the shaft steadying the running, which is apt to be irregular, as the saws cut on the down stroke and run free on the up stroke. The combined connecting-rod and crosshead, D, couples the crank-pin to the two long rods, E, E, which are pivoted to the saw frame, F, sliding between the guides in the frame, A.

The timbers, G, G, bolted to brackets on the frame, A, are for the purpose of carrying rails upon which a *rack carriage* runs, the top of G being at the floor level of the mill, the rest of the frame and driving mechanism lying, therefore, below the floor. A bit of the table is seen at H, and on top of this the log is supported in a manner which will be seen later. The *feed* to this table is effected through a row of rack teeth on its under side, worked by pinions on a shaft lying immediately below it, and connected by two sets of gears with another shaft, J, having a large wheel with a rim of V section. This is given a partial rotation at each down stroke of the saw-gate by a smooth pawl cut eccentrically to jam into the vee as the lever, L, lifts it, through the medium of the short slotted lever, M, rocked up and down by a lever coupled to the top end of one rod, E. The position of the lever L on M is variable by means of a short screw and a hand-wheel which makes provision for obtaining different rates of feed to the balk, N. The device, which is universally adopted, is termed the *silent rachet* or *silent feed*. A rapid motion can also be imparted to the table in either direction for bringing a log up quickly or returning the carriage for another log.

The belt pulleys, O, carry open and crossed belts, either of which may be slipped on to the central fast pulley to drive through the shaft, J, clutched into or out of action, and connected to the pinions driving the table through two sets of gears having varying ratios, either of which can be employed, for fast or slow movements. The timber is held down firmly by rollers, P, on shafts which are supported in sliding racks moved up and down by pinions and gears, operated by the handwheels, Q, Q, which have weighted levers allowing a little freedom of movement should the log require accommodation in passing through. Two rollers are located beneath the log, so that it is held steadily.

Figure **4** illustrates a class of dog commonly employed for gripping the log at each end upon the rack table, the pincers or jaws being connected with toggle levers, and opened or closed by means of a central screw. The set of levers is carried on a shaft held in bearings, and a screw is placed at one side to enable the attendant to adjust the dogs laterally to suit crooked timber.

Log Frame with Roller Feed. The roller-feed frames, of which an example is given in **6**, propel the log by the contact of fluted rollers, positively driven. In some machines rollers are used only beneath the logs, the top rollers being simply plain, but in the *compound* types both top and bottom rollers are driven, thereby giving a powerful drive which will even carry logs covered with ice past the saws without slipping. In the drawing of the machine (also by Messrs. Haigh) several points of similarity to the previous design will be noted, but the mode of driving is different, being effected by belt pulleys located on the shaft at the bottom, rotating crank-discs at each end, and moving connecting-rods on the outside, connected to extensions of the saw-gate. The feeds are derived similarly to those already described, with a silent V wheel, but the motions have to be conveyed to the four shafts of the serrated feed-rollers, which are revolving simultaneously, by connecting them up with mitre gears and shafts. The log is supported on two carriages, one being shown in the side elevation and separately in plan view, running by trolley wheels on the rails secured to the top of the beams that are flush with the mill floor. Each carriage has a pair of pivoted arms carrying screws which clamp the timber, and as the arms are held on a shaft they are able to slew a little should the log rise or fall in passing through the feed rollers. The screw forming part of the pivot shaft [see the plan, **6**] provides for side adjustment to suit crooked logs. The machine is arranged also to saw deals, for which purpose a couple of *fences* (seen in the front view) are placed in position, and side pressure is given to the deals by flanking levers which are mounted on vertical shafts, twisted by quadrant racks operated by handwheels. When it is impossible to get out

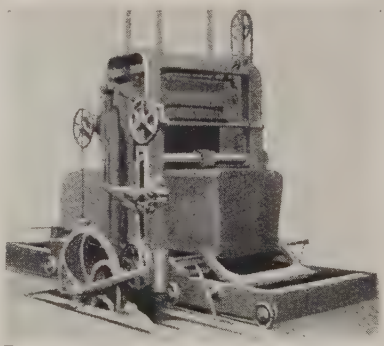
5873

deep foundations in the mill, *top-driven* frames are installed, by which the length of frame below the floor is reduced to a small amount.

A very heavy Robinson frame, constructed for cutting up massive logs of round or square section, is illustrated in **7**, with a big log in place. The capacity of the largest machine is up to logs 48 in. by 30 ft., the pulleys making 100 revolutions per minute. The connecting-rods work on the outside of the frames from crank-discs below the floor, and the feed is by a silent ratchet and fluted rollers of *duplex* or compound pattern, the bottom ones being driven by spur gears and the top ones by pitch chains. The frame shown is carrying 36 saws.

Semi-Portable Frames. In what are called *colonial* breaking-down frames, the uprights and horizontals are often constructed of timber, built on the spot where the machine is erected, the makers of the frame supplying only the iron portions. The machines are then of *semi-portable* type—that is, they can be readily dismantled and removed.

Portable Frames. The strictly *portable* frames are mounted on trolley wheels, as in **8** (A. Ransome & Co., Ltd.), with shafts and all appliances for hauling. The machines are drawn into an excavation of sufficient depth to allow the horizontal sleepers, on which the log carriages travel, to rest upon the ground; the carriages run upon the rails, which may be continued out to any length desired. Belt driving is adopted, working a central crank, connected to the crosshead of the saw-gate. The feed is derived from an eccentric or slotted disc on the face of one flywheel working up by a rod to the silent V wheel, this being a method often followed instead of getting the movements from the saw frame itself.



7. HEAVY ROLLER-FEED LOG FRAME

Double Frames. *Double* log frames have two sets of saws, which operate on two different logs simultaneously, though at different rates of feed, if necessary. The capacity is thus greatly increased without much increase in space occupied. In what are termed *equilibrium* frames, the two sets of saws are worked up and down by connecting rods attached to cranks at different angles, so that as one frame is rising, the other is going down, thus balancing the irregular forces, and enabling steady running to be obtained without the use of heavy flywheels.

Steam-driven Frames. The steam engine is applied to log frames in a direct manner, by attaching the piston-rod of a cylinder placed on top of the frame to the crosshead of the saw-gate to produce the reciprocal movements. Two advantages accrue: deep foundations are dispensed with, and the machine is independent of belting and other engines, which may be already fully loaded, although at the same time there is steam to spare from the boilers. A steadying effect is obtained by carrying connecting-rods down from the saw frame to cranks on a flywheel shaft just below the feed rollers, this shaft also operating an eccentric to work the cylinder valve. Sometimes one of the flywheels is turned to receive a belt, driving on to the pulley of a separate circular saw for re-sawing the product of the log frame.

The rates of feed employed on log frames vary from 6 in. to 5 ft. per minute, with quick return. The travel of the saw teeth ranges from 450 ft. to 800 ft. per minute. The output, of course, varies enormously, according to the class of timber and the condition of the saws.

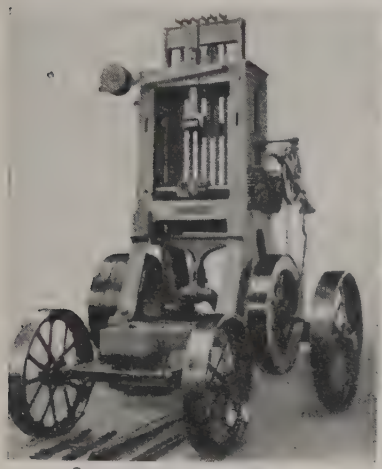
Deal and Flitch Frames. The deal and flitch frames are constructed for re-sawing deals and flitches *broken out* from logs in the log frames. They bear some resemblances to the latter, especially in methods of driving, but the feeding arrangements are modified, chiefly because the deals are not irregularly shaped like logs. The double principle is also carried out more frequently for sawing two deals at once, and even then the frames are narrow by comparison with those for logs, as the deals are sawn edge-ways up. Overhead-driven and under-driven frames are employed, as in log machines. The timbers are fed through the machines by fluted rollers, which are pressed on the under side and top of the deals as well as at the sides. These side rollers are carried on springs to take up automatically any unevenness in the thickness of the deals. The frames are arranged to take four of five saws per inch in width, as against the coarser pitching in log frames, of one per inch, or thereabouts. Speeds are higher than for log sawing, ranging from 600 ft. to 900 ft. a minute, and feeds up to 8 ft. per minute.

Double Deal Frames. The double feed frames are usually preferred on account of their greater output, the single ones being employed in sawmills where there is not a sufficient volume of work to keep a double frame properly occupied. The speeds of frames range up to as high as 360 revolutions in the equilibrium types, but these high speeds are not possible when the frames are worked from a single-throw crank-shaft. The reason for combining deal-sawing apparatus with a log frame is that many users have insufficient work to warrant the installation of both a log frame and a deal frame. The combination machine, therefore, meets cases of this kind. After a number of logs have been broken down into deals and flitches, the deal-sawing apparatus can be set up, and boards can then be cut.

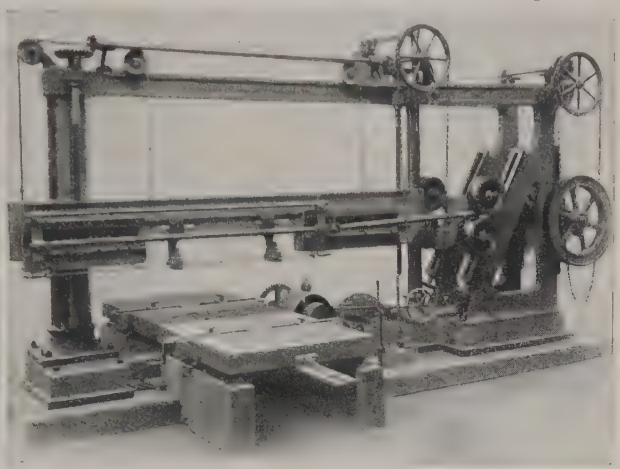
Horizontal Saws. We may now leave the vertical reciprocating saws and consider those of horizontal type, which are confined to one pattern, employing either one or two blades. They are used for cutting up hard and expensive woods, and, though not so rapid in action as the frame-saws, they possess some advantages.

A very thin saw may be employed, which wastes a minimum of wood in sawdust, and the power consumed by the machine is small. A very important point is that, the boards being sawn but one at a time, the sawyer may examine the timber, and alter the cut for any one board in order to avoid bad places concealed inside. The *figuring* of the timber may also be watched when cutting up for wainscoting or cabinet-work. In a frame-saw there is no chance to do anything of this kind, because all the blades are set, and must complete the division of the log simultaneously.

A 36-in. horizontal *board-cutter* (as these machines are called) is shown by elevation, plan, and end view in **12** (Haigh, Gruban & Co.). The framing comprises a bedplate supporting two standards, on the front faces of which a saddle, A, may be adjusted up and down by screws, operated by a hand wheel and bevel gears, or through a belt-pulley. The saw-blade, B, is strained between the extremities of a light steel frame sliding in guides on the saddle, A, the blade being passed through two wood-packed guides, seen inside and below the saddle, these coming close up to the log. A long connecting-rod, C, is coupled with a pivoted joint to the end of the saw-frame, and embraces the pin of a bent crank at the other, the crank being turned by a belt-pulley, which, together with another, is made as a heavy flywheel. The crank throw is 14 in. The *log table*, D, travelling by rollers upon vee-shaped rails, is racked along through the medium of a set of gears which derive their motion in the first place from the stepped cones at E, driving thence a worm, worm-wheel, and rack pinion. High-speed movements, in either direction, can be given to the table by open and crossed belts on the pulleys, F, connected to the shaft of the table pinion. The table, which is made in any length required, has dogs at its edges, set inwards by screws, to grip the log and prevent it from rolling about.



8. PORTABLE LOG FRAME

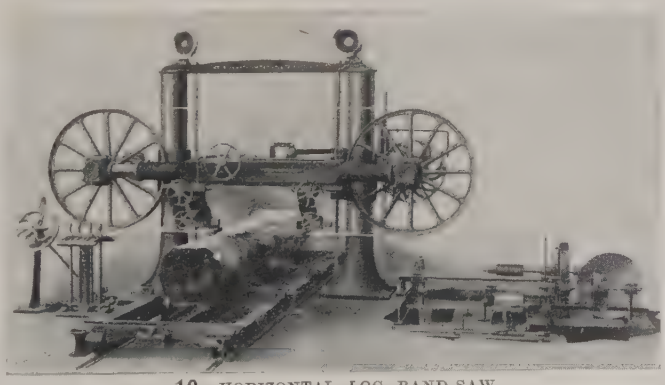


9. HORIZONTAL BOARD CUTTER

Figure **9** gives a good idea of the general appearance of a saw-frame, with a single blade, one of Messrs. Robinson's designs. The cross rail is adjustable on the pillars by hand or by power, and a graduated scale, recessed into one pillar, enables the sawyer to see the depth of cut in the log at a glance, and to make his adjustments accordingly. The crank-shaft, which is balanced, lies between the sloping standards to the right, and, with its bearings, is adjustable up and down the sloped guides, to keep the connecting rod in a central position relative to the saddle, as the latter is set high or low to suit the cut. The log carriage, a short portion of which is seen in the photograph, is fed by variable friction gearing, and returned at a high speed, all the controlling levers being brought to one place for convenience of operation.

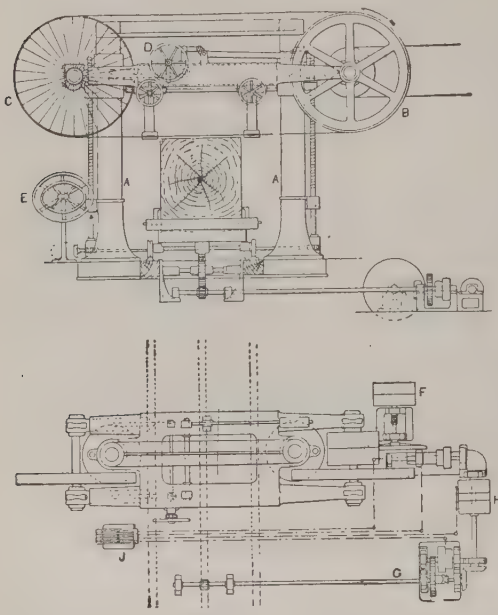
As the saws in the classes of machines described cut in both directions, the feed is continuous. The speeds of horizontal saws average 1000 ft. per minute. Rates of feed lie between a few inches and 5 ft. per minute.

Band-saws. All the reciprocating saw machines which have been described suffer from one defect—slowness of cutting. There are two classes of saws which work at a far greater rate, the band and the circular. The former especially is entering into rivalry with the frame-saws, and in many cases ousting them from their position in the mill as log-converting machines, a fact due to the enormous cutting capacity of the saw, a steel ribbon having teeth running at a rate of 7000 ft. per minute. The feed is correspondingly increased, ranging from 5 ft. up to 80 ft. per minute. A subsidiary advantage also gained by using band-saws is that, the blades being very thin (from 16 to 19 gauge, B.W.G.), the waste of wood in the kerf (say, $\frac{1}{11}$ in. wide) is greatly lessened by comparison with the thicker frame-saws; when dealing with costly timbers this matter cannot be ignored.



10. HORIZONTAL LOG BAND-SAW

Horizontal Band-saws. Band-saws are constructed in two types, horizontal and vertical. A horizontal machine by Messrs. Haigh, Gruban & Co., illustrated in front view and plan by **11**, embodies the principal features found in such saws.



11. HORIZONTAL BAND-SAW

Two circular pillars, A,A, bolted to a bedplate, receive sockets supporting a cross-rail, in the ends of which the bearings for the wheels, B, C, are held in pivots, to let the wheels align exactly with the saw. The pulley B is driven from fast and loose pulleys on its shaft, and it is of heavier construction than the other pulley, C, as the latter is an idler, driven only by the saw. The blade passes through *guides* seen adjacent to the log. Tension is given to the saw by pushing out the pulley C in a socket bearing by means of the handwheel, D, operating a worm gear and screw. A balance weight arrangement (seen above the cross-rail, adjacent to D) maintains an even tension on the blade when running by keeping a pressure on the pulley socket. The entire affair is raised or lowered on the columns, A, A, by two screws, worked from worms turned by a horizontal shaft driven through bevel gears from a handwheel, E. An indicator shows the attendant how thick a board will be cut.

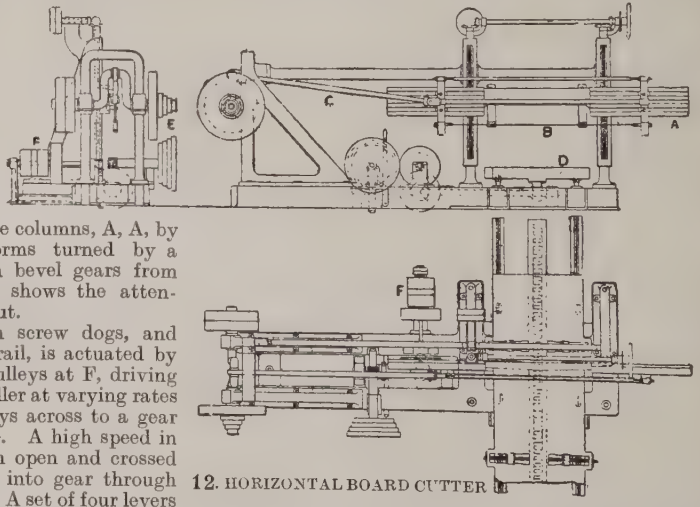
The log carriage, fitted with screw dogs, and travelling upon a V and a flat rail, is actuated by rack and pinion from the belt-pulleys at F, driving a friction disc, which rotates a roller at varying rates and communicates by belt-pulleys across to a gear turning the rack pinion shaft, G. A high speed in either direction is obtained from open and crossed belts on the pulleys, H, thrown into gear through bevels, and a claw clutch with G. A set of four levers at the stand, J, connects by rods to the three belt-shippers and the claw clutch, so that the sawyer has complete control.

Figure **10** shows a machine by Messrs. Robinson, with a log in position, and the *feed works* shown by the breaking away of the floor. The attendant's stand in front of the left-hand pulley is also clearly shown. The pulleys are 5 ft. in diameter. The friction feed gear gives any speed up to 60 ft. per minute, and quick movements of the carriage are obtained independently.

Vertical Band-saws. The *vertical* log band-saws are rather less expensive to construct than the horizontal types, and they occupy less width in the mill, while they are capable of breaking down the largest sizes of logs. An objection to the design is that the lower pulley is partly or wholly buried under the floor of the mill. At the same time, very large pulleys can be used, as much as 9 ft. in diameter in the biggest machines, with wide and powerful blades. The difference in the attitude of the saw, lying as it does vertically, necessitates presenting the log sideways, and as the pulleys are fixed the log must be fed inwards for each cut.

Feeding Devices. Two modes of feeding other than by rack and pinion are employed largely in the States. *Rope feed*, suitable for very long logs, embodies a friction drive, or a separate steam engine to wind an endless wire rope around a drum, and pull the carriage in one direction or the other, for cut and quick return. Direct-acting *steam feeds* include a long steam cylinder lying below the carriage, with a piston-rod connected to it, so that as the piston is driven in either direction the carriage is drawn along, the rate of feed being variable by the sawyer admitting more or less steam by a controlling valve. A combination of a steam cylinder and a rope passing over pulleys is used.

Loading Appliances. A special class of appliances is employed for loading logs on to the carriages from a sloping *skid* upon which the logs are stored, lying parallel with the carriage. The *log turner* is a kind of friction winch, operating a chain, at the end of which there is a hook, to engage in the log, and roll it into position on the carriage, after which it may be turned and adjusted. The *log loader* comprises a steam cylinder fitted below the bottom of the log skid, and actuating arms



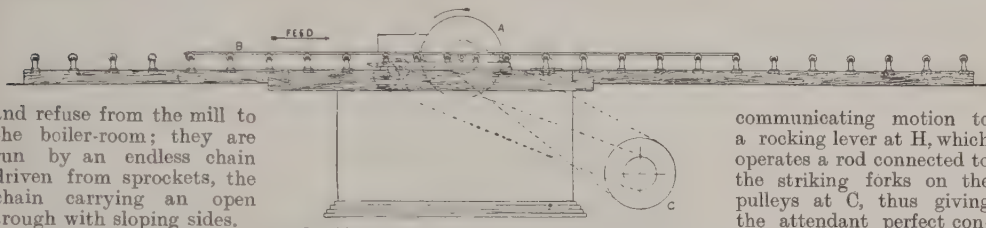
12. HORIZONTAL BOARD CUTTER

which release a log and allow it to roll on to the carriage of the saw. A foot pedal operates the steam valve. The *steam nigger* is the quickest

means of handling; it consists of a long, vertical *arm*, to which are attached hooked spikes. The arm is moved up and down, or canted by two steam cylinders of direct-acting type, and the spikes may be made to catch in a log, pull it from the skid, roll it on to the dog carriage, and turn it into any position most convenient for sawing. The skids are supplied with logs from a haul-up slipway.

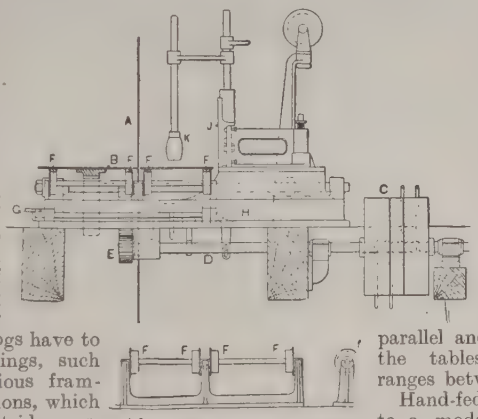
Live rolls, consisting of a train of rollers positively driven by bevel gears, are useful for transferring material from the band-mill to the re-saws, and they save a great amount of time which would be occupied by hauling about by hand and cranes. The timber is transferred to or from the live rolls by mechanism which avoids handling on the part of the men; the lateral motion is produced by an endless pair of chains, which are raised into contact with the lumber when desired, or by spiral rolls making contact underneath.

Sawdust conveyors are used to transport the dust and refuse from the mill to the boiler-room; they are run by an endless chain driven from sprockets, the chain carrying an open trough with sloping sides.



13. 72-INCH CIRCULAR SAW RACK BENCH

Circular Saws. The circular saw as a log-converting machine possesses the advantage of great speed of cutting, and outdistances the reciprocating saws easily in this respect. As a set-off, two objections are: that there is a considerable waste of wood in the kerf, and the saw takes an excessive amount of power to drive it, due to the leverage of the teeth acting on the periphery of the disc. Notwithstanding these objections, circular saws are employed when logs have to be cut into heavy scantlings, such as sleepers, posts, and various framings of square or other sections, which involves taking off the outside portions. They are not used to such an extent for the cutting of logs into very thin boards or strips of different sections.



14. DETAILS OF RACK BENCH

Rack Benches. The log saws are constructed with travelling tables, which carry the logs past the projecting saws. There are two patterns—one in which the tables are divided to embrace the saw on each side, the other in which the logs are held on dog-carriages and presented laterally to the saw, enabling successive settings to be made for cutting off planks or boards.

Figure **13** gives a side elevation of a *rack bench* for a 72-in. saw (Messrs. Haigh, Gruban & Co.), from which the elements of such machines may be studied.

The saw, A, runs in fixed bearings, and the timber rests upon the table, B, which has a longitudinal opening to receive the saw. The table is made of steel plate, and moves upon a series of rollers, seen underneath, resting upon a timber framing.

The driving of the saw is effected through the line shaft and pulley at C, belted up to the saw mandrel; the table drive is also derived from a pulley at C, from which a belt goes up to a pulley connected to a train of spur gears, coupled with the rack underneath the table. The rates of feed can be varied from 10 ft. to 40 ft. per minute, with a quick return movement at 120 ft. per minute. Some details of the machine are illustrated in **14**, the saw being seen at A, the table at B. The feed is from pulleys at C, carrying open and crossed belts, either of which is shifted on to the central fast pulley, driving the shaft D, and thence a train of spur wheels, which end in a pinion meshing with the rack fastened underneath the table B, to the left. The four rollers supporting the table across its width are seen at F F F F, all of these being mounted upon a common spindle. There is a foot pedal at G, which, when depressed one way or the other, turns a short shaft having mitre gears communicating motion to a rocking lever at H, which operates a rod connected to the striking forks on the pulleys at C, thus giving the attendant perfect control over the feeds and return. The *fence* at J is for guiding timber in a straight line past the saw, and to keep the timber against the fence the *pressure roller*, K, is brought into use. It is held on an upright bar that can be pivoted in its socket, and pulled over by a cord attached to a balance weight, the cord passing over the pulley adjacent. In this manner the timber is pressed up to the fence, and the resulting cut is parallel and smooth. The length of the tables in these rack benches ranges between 20 ft. and 40 ft.

Hand-fed rack-tables are made only to a moderate extent, the motion being obtained from a crank handle turning the rack pinion. No fastenings are necessary for the logs, as their weight is sufficient to keep them steady. Round logs are flattened on the bottom to make them stand firmly, or else wedged and packed to keep them from shifting.

Rack Benches with Dog Carriages In **15** we illustrate a machine (Messrs. Thos. Robinson & Son, Ltd.) in which a log is seen gripped by some of the quick-acting dogs of the carriage. The carriage as shown is arranged to take logs up to 30 ft. in length, but there is practically no limit in this direction. The circular saw is 66 in. in diameter, and runs at 500 revolutions per minute. There are three speeds, or rates of feed, to the log, and a rapid return.

A circular steel disc of wedge section is placed immediately behind the saw, to enter the kerf after it, and force the two sawn portions apart slightly, thus relieving the saw of undue side-

friction, which would tend to heat the saw, greatly augmenting its work and decreasing output. There is a long, vertical roller located in a sliding bearing in advance of the saw, against which the log takes a bearing when travelling. The roller is adjustable by a hand wheel, and serves as a fence.

Double Saws. As the capacity of a circular saw is limited as to the diameter it will cut, it cannot be employed to cut up big logs. But by mounting another saw above, the capacity is much increased, as the two blades, working up from below and down from above, can reach through a greater thickness. The top saw is usually of smaller diameter than the bottom one—say, in the relation of 72 in. and 36 in. in the case of the larger machines. Figure **17** represents a double machine, a type similar in all other respects to **15**. The upper saw is carried on a spindle in sliding bearings on an upright, and the driving belt passes around a jockey pulley by which the slack is taken up. The teeth of the saws face in opposite directions to each other, and the direction of rotation is also opposite. The two are brought as close as possible without actually touching.

Re-saws. We now come to a group of machines termed *re-saws*, the function of which is to cut up deals, flitches, planks, etc., which have already been sawn out from logs, into portions of various sizes. The deal frames already described are strictly re-saws, but there are also the smaller band and circular saws, which are both rapid in operation and handy in respect of the variety of work which they can be adapted to turn out. Adjustments can be made very quickly to cut a small number or hundreds of similar pieces. A feature in which these circular and band re-saws differ from log-sawing machines is that the tables do not usually travel, but the timber, being more or less even, is slid along smooth surfaces, with or without the help of rollers. The three chief methods of feeding are rope, chain, and roller. The *rope-feed* is suitable for irregularly shaped timber or for driving small logs. The bench [**16**] (Thos. Robinson & Son, Ltd.) embodies a cored casting, carrying three bearings for the saw spindle. The timber is drawn along on the top of the table past the saw by a rope fitted with a drag hook at the end, as seen, and the rope is wound around the drum at the left-hand end of the bench. Four rates of speed, from 15 ft. to 60 ft. or upwards, per minute, can be obtained through the medium of cone pulleys, and the movement of the rope can be instantly started or stopped by throwing a clutch in or out of gear. The speed of the drum is reduced by back gears. The rope is passed up over a roller at the edge of the table, this roller enabling it to run over the edge without friction. In cutting long pieces which overhang the ends of the bench to a considerable distance, some extraneous support is required; this is afforded by a *trolley* at each end, running on lines of rails laid down in line with the machine. The timber, therefore, rests on one trolley, and gradually leaves it to pass over the bench past the saw and be supported by the other trolley. The fence for keeping the timber straight is fitted with a counterbalanced roller, pulled over by a weight, in a similar manner to that described in connection with **14**.

15. CIRCULAR SAW LOG MILL

16. SAW BENCH WITH ROPE FEED

Some rope-feed benches have, instead of the small drum, a large grooved wheel placed with its spindle at right angles to the saw mandrel. It lies close up to the end of the bench, and the rope is conducted over a small pulley on to the table. The rope is subjected to less strain while running on the large pulley than it is on a small drum. When the rope has been pulled along to its drum or wheel, the return, in readiness for another feed, is effected by pulling at it with the hands, the clutch being thrown out meanwhile, so that the drum revolves freely upon its spindle.

Chain-feed Benches. *Chain-feed* benches, which are employed principally for cutting up sleepers and the various short pieces of waggon framings, have a greater output than the rope-feed machines, because the action is continuous. One, or in some cases two, endless pitch-chains are driven over wheels at the ends of the table, and they run in grooves past the saw. The timber is fed by the pressure of dogs dropped on to the chains between the links. As the chain, or chains, are always running, the timber can be pushed along as fast as it is placed in position. Rates of feed vary from 40 ft. to 120 ft. per minute. Some machines will split 2500 balks in a day of ten hours, resulting in the production of 5000 sleepers.

Roller-feed Benches. The best method of feeding, providing the work is suited thereto, is by continuously revolving *rollers*, either horizontal or vertical, the latter method predominating. A horizontal roller bench is shown in **18**, one of Messrs. Robinson's designs. The rollers, which are smooth, lie at the ends of the table, and their top surface is raised slightly above that of the table. They are driven at any one of three different speeds, and the weight of the log, or flitch, combined with the downward pressure of the revolving saw, gives sufficient friction to feed. The rollers can be reversed at a quick speed, in order to return heavy pieces after each sawing. The largest of these machines takes saws up to 5 ft. in diameter.

One of the most useful forms of roller-feed bench is that shown by the drawings in **19** of a bench taking 42 in. saws, and having a table measuring 6 ft. by 3 ft. (Messrs. John Sutcliffe & Son, Ltd., Halifax). The saw spindle, A, is supported in two bearings, the outer one being placed outside the driving pulley. The latter is made slightly larger than its adjacent loose pulley, on which the belt is slid to run idle and slack. The belt slipper is seen to be actuated by a pivoted lever worked from a rod passing through to the front of the

bench, where the control is best effected [see the plan view]. Removable plates are fitted over the bearing and the spindle end, to facilitate examination and the changing of saws. The feed rollers, B, B, serrated in ratchet form, are revolved against the timber, and force it along while making contact with the fence, C. A number of small plain rollers are set in the fence, to relieve the friction. Lateral adjustment, to suit the thickness of wood which it is desired to cut, is effected by a transverse screw passing through the table, and turned by a small knob seen near the right-hand end. Quick adjustment is provided for by a locking handle, which releases the fence, enabling it to be shifted to and fro instantly.

The mechanism of the feeding rollers includes a radial arm, D, pivoting upon a pillar bolted to the table, and carrying a rod in clamp bearings, which rod holds the vertical shaft bearing of the rollers, and is adjustable in the clamp bearing to accommodate different diameters of saws. Pressure against wood is produced by a rope or chain pulling at the side of the bearing, leading over guide pulleys at E, to a weight at F. The rollers are driven in a positive manner by a pitch chain on the top of the shaft, worked from another shaft, G, which passes down through the table pillar to the floor, where a worm drive is received from a four-stepped pulley, H, belted from another pulley, J, which derives motion from a pair of pulleys, one on its shaft and one on the saw mandrel at K. A claw clutch, put into mesh by a handle at the front of the bench, enables the sawyer to start and stop the rollers instantly; the clutch works into teeth on the stepped pulley. At each end of the bench a smooth roller rests in bearings to take the weight of the wood as it passes over, and so to lessen the friction. If it is desired to use the machine without the roller feed, the radial arm can be swung out of the way, leaving the bench free.

17. DOUBLE SAWS FOR LARGE LOGS

18 HORIZONTAL ROLLER-FEED SAW BENCH

Combination Feeds. Several types of benches are constructed with a combination of feeds, as rack and roller, or rope and roller, the idea being to use one for rough logs, which cannot be fed by rollers, and the other for regular pieces, like deals. Such machines are very useful to sawyers who cannot have two separate benches for the different classes of work.

Canting fences are designed for use with the roller-feed benches, to cut feather-edged boards, etc. The fence tilts bodily with its rollers, so throwing the stuff over in relation to the saw.

Band Re-saws. Band-saws for re-sawing are not quite so handy as the circular saws for general work, but they are popular in many cases on account of the thinness of the blade and the minimum of waste incurred in cutting. It is not a difficult matter to fix a self-acting feed to a band-saw table. In a few types a short rack-operated slide is placed on top of the table, to traverse the stuff, but the majority of machines use friction rollers, either one set, propelling the wood in contact with a fence, or a double set, both of which roll against the timber.

Cross-cut Saws. We have to note the *cross-cut* saws, which are employed for parting off deals, planks, boards, etc., to definite lengths. A good deal of this work is of a repetition character, especially for box-making and joinery, and means are provided for cutting numerous pieces to gauged lengths by the employment of fences or guides, or by putting two or more saws side by side to cut off the ends accurately. The *pendulum* saw [20] (John McDowall & Sons, Johnstone) is a pattern that is very commonly used. It comprises a rigid frame swinging in trunnion bearings on brackets attached to the roof or the wall, and carrying pulleys which are belted down to the saw spindle at the bottom; the saw can therefore be swung to and fro by pulling at a handle in the front, while a counterbalance, on levers at the upper part of the frame, draws the latter backwards automatically on letting go the handle, so keeping the saw out of the way until it is required. The spindle is started and stopped by shifting the belt on the fast and loose pulleys at the top shaft. The stuff to be parted is supported on the special bench seen in the illustration, a gap being cut through where the saw swings across.

For cutting pieces to uniform lengths there is provided an adjustable *stopper* that can be clamped in any longitudinal position, for the end of the timber to butt against, and so locate it accurately. To save lining off the lengths of timber previous to cutting various pieces, it is sometimes the practice to fit a metal rule with clamp stops, so that accurate sub-divisions of the inch can be made by the sawyer. The largest saws used in these pendulum machines usually range up to 36 in., capable of working to 12 in. deep, but in a few instances saws up to 60 in. are employed for heavy work, including small logs.

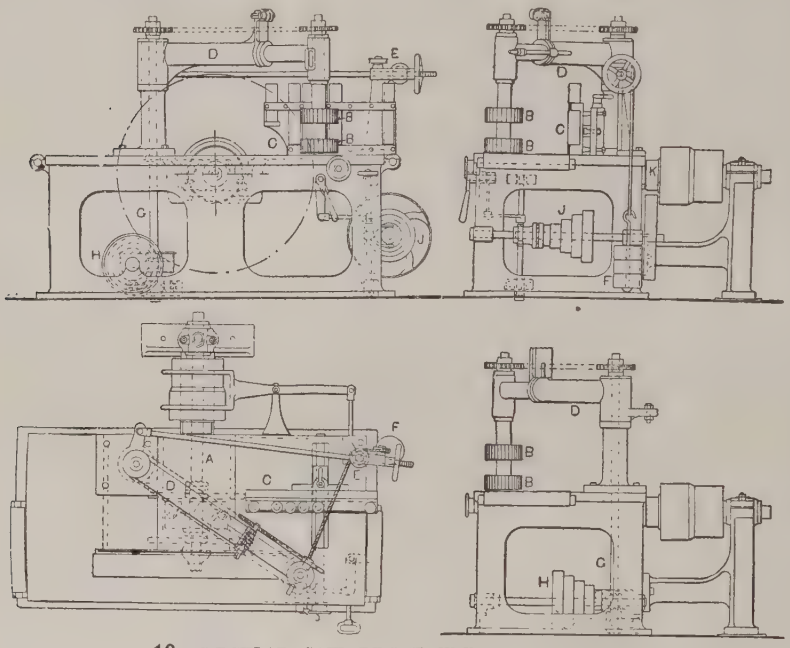
A guard is always fitted over the upper portion of the saw, as a protection against injury to the attendant at the machine.

Sliding Table Cross-cut Saw. The pendulum saw is especially handy for long or heavy pieces of wood, as they remain stationary. But when the length and weight of a piece permits, one of the several special cross-cut benches can be brought into use. The object is to traverse the timber across against the saw teeth, this being effected generally by a table running by rollers upon rails. The spindle is made to rise and fall in some of these machines. Double or *equalising* saws, which trim off the two ends of a piece simultaneously, comprise a table travelling above a bed on which two headstocks are set in any desired position, to give variable widths. As the stuff is drawn over on the table the saws part it off at both ends simultaneously. Lengths from 4 in. up to several feet are handled on these machines.

Multiple Cross-cut Saws. *Multiple* saw machines are principally of two classes. In one a number of saws are set side by side to the required distance to part off a length of stuff into several pieces, such as paving blocks, the movement of the saws or of the wood carriage being continuous, so

that at each stroke a piece of wood is completely cut up. Sometimes the saws are of differing diameters, gradually getting smaller, so that the work of sawing is gradual, and does not put so much strain on as though all the blades penetrated simultaneously. As many as 30,000 paving blocks can be sawn out in one day on these machines. In the other class of machine several saws are set in a long table, at differing distances apart, in order that stuff may be cut to various lengths, the pairs of saws being set in advance of each other, or, alternatively, sets may be caused to disappear below the table, leaving only those standing up which are required. The travelling tables are abolished in certain designs, and their functions performed by endless chains, having dogs which engage in the sides of the timber, and push it against the saws.

One particular design of bench, which differs from those already described, is intended to deal with heavy planks and scantlings that are too heavy to be conveniently handled about and fed to a saw. The timber is laid upon a fixed table, and cut by a circular saw projecting up through a slot therein, the spindle running in bearings that can be fed longitudinally on a subsidiary bed. The foregoing machines for re-sawing and cutting off prepare the stuff for further treatment (when required) on other kinds of saws, which we shall now deal with.



19. CIRCULAR SAW BENCH WITH ROLLER FEED

Plain Benches. The lighter types of circular and band saws, which are not fitted with mechanical feeds, appear in several forms, modified variously to suit the classes of work they have to do. The *plain* circular-saw benches resemble those in **18** and **19**, but without the special attachments required for feeding, the only fitting being a fence, which is adjustable to and from the saw. The usual method of attaching the fence is by means of a circular steel bar at the end of the table, enabling lateral adjustments to be made, or, if necessary, the fence can be thrown back out of the way, leaving the table quite clear for cross-cutting. For bevel cutting, a canting movement has to be provided for the fence. The larger machines have rollers placed at each end of the table, similarly to **19**, to assist in the easy handling of heavy pieces.

Portable Benches. *Portable* saw benches, mounted on four trolley wheels, are used by shipbuilders and contractors, the machines being run to any locality where they are wanted, instead of transporting the timber to the saw. An electric motor drives the spindle direct, and the table is swivelled upon a turntable, to present the saw at any horizontal angle to the work, instead of shifting the latter.

Rising and Falling Types. The range of the plain benches is rather limited, and other types are therefore used for an extended class of operations, especially in joinery work. In one type, with *rising and falling* spindle, the spindle may be moved upwards or downwards in relation to the table; in the other the movement is imparted to the table. The object in each case is to vary the depth of cut, so that the machines are adapted for grooving, tonguing, rebating, beading, and tenoning, by fitting special saws or cutter blocks to the spindle. The saws are either *thick* for grooving, or *drunken* for grooving and tenoning. The objection to altering the spindle height is that the belt-driving arrangements are complicated by the variations, and the rising and falling table machines are therefore preferred. The only disadvantage possessed by them is that the varying height of the table is sometimes apt to become awkward to the sawyer, but there is not much weight in this objection. There are two devices employed for operating the tables—racks and screws. The latter are better for the purpose, and are used in the majority of machines.

A groove is sometimes planed longitudinally in the tables to take a sliding fence, for use in cross-cutting, the fence lying at right angles to the main one; mitre cutting can be done by attaching a supplementary mitre fence.

Dimension Saws. The *dimension* or *two-spindle* saws are designed for both ripping and cross-cutting, and have two saws sharpened for cutting with and across the grain respectively. The spindles run in bearings at the opposite ends of a strong arm, pivoted about its centre in order that either of the saws may be brought up to the top ready for action, a hand wheel accomplishing this movement. The drive to the spindles is arranged so that the lower saw is thrown out of action. The special value of the dimension saws lies in repetition work, where large numbers of pieces have to be sawn

to uniform sizes, as in cabinet work, pattern making, parquetry work, etc. Angular and bevel sawing is readily done by the aid of the canting and swivelling fence.

Universal Benches. *Universal* saw-benches embody the two-spindle arrangement, together with a tilting motion of the table, to present the stuff angularly in relation to the saw. Several auxiliary fittings, as gauges and angular fences, are provided, so that every class of sawing can be done, to build up the most intricate framings accurately.

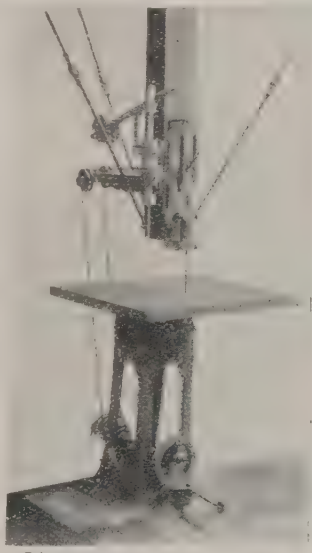
Band-saw Machines. The band-saw machines are particularly useful for general sawing which includes curved work, because they can tackle sweeps for which the circular saw is useless. The chief drawback is the trouble caused by breakages of saws, though this is often avoidable if care is exercised.

Figure 22 gives a good idea of a typical machine in side and front elevations, the example being from the practice of Messrs. Thomas White & Sons, Paisley. The saw pulleys are of 30 in. diameter and make 400 revolutions per minute. The framing, A, is of box section, cored out, which affords a very stiff form, able to resist the effects of vibration at the high speed necessary. The cast iron pulleys, B, C, have no flanges, and are rubber tyred to avoid damage to the saw teeth, and the top wheel C is mounted on a spindle which runs in a hinged bearing that can be tilted to make the saw run on any part of the pulley. The hand wheel, D, operates a screw which slides the bearing of the wheel C up or down to suit the length of saw, and a constant tension is maintained afterwards by the coiled spring at the top. A balance weight and lever is fitted in some machines instead of a spring. The belt drives to the fast and loose pulleys at E, and is shifted across to start or stop the machine by the forks and hand lever passing through the frame. F is the table, constructed with an extension to cover over the pulley B and prevent pieces of wood from falling on it. The table is tilted or canted for angular sawing by turning the hand wheel, G, which rotates a worm engaging in a worm segment on a quadrant bolted to the table, and turning the latter upon its pivot. The saw passes through a timber casing at H, and through a *guide* at J. Rolling contact is the proper method, and there are several designs of guides in use. The blade is confined sideways between two hardwood strips, adjustable for width of opening. The guide is brought down as close as possible to the stuff being sawn, and is therefore held in a vertical bar passing a socket in the frame A, in which it is clamped in any position by a hand screw. The bar is counterbalanced by a rope and weight to prevent it from dropping when the hand screw is loosened. The saw passes through hardwood strips let into the table, and a rotary guide is also often fitted below the table, though in some instances nothing but wood guides are employed. The lower saw pulley is in many machines provided with a little brush to keep the pulleys clear of sawdust, etc.

A fence is fitted to the tables of band-saws when wanted, to guide straight stuff past the saw, otherwise the operator must work to a scribed line on the timber, as in sawing curves.

20. PENDULUM CROSS-CUT SAW

Fret or Jig or Scroll Saws. These have but a limited scope, and are used for internal cutting and scrollwork which a band-saw could not manage, as the fret-saw blade can be disconnected and passed through a hole in the piece to cut out a central portion. The mechanism is simple, comprising a small crank-disc driven at a high speed, working a connecting-rod which reciprocates the saw-blade, gripped in sliding holders above and below a table. The rate of working is about 1000 strokes per minute. There are two types of machine; one has a curved cast-iron framing reaching round the table and up to the top holder, the framing, therefore, preventing very large work from being placed in position. In the other type, a suspended tension head of wood is used, consisting of a vertical beam attached to the ceiling, and strained tightly by three tie-rods, put in tension, by nuts on right and left-hand screws [see 21]. The entire space around the table is free, and work of any area can be put on. In the machine illustrated, tension is given to the saw by means of a couple of spiral springs, which constantly maintain an even pull. A boring attachment is shown alongside the framing, to prepare work by making holes where they are necessary to insert the saw.



21. FRET-SAWING MACHINE

Saw Details. Devoting now a brief space to the consideration of the saws which are used in the various machines hitherto described, we begin with the frame-saws. The types employed in the log and deal frames [23, A and B] are long, flat blades, or *webs*, to which are riveted *buckles* [*a*] held at the bottom end of the swing frame by a hooked portion, or by a head, and strained up in the top by *tillers* and cotters. Enlarged views of the buckles and cotter are given in C. The horizontal board-cutting machines have saws like D, attached and strained with buckles and screws tightened up with nuts.

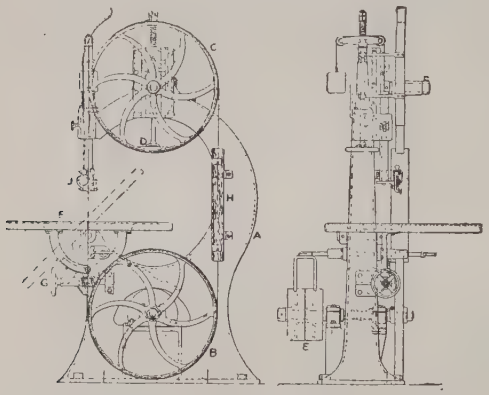
The shapes of the teeth for such saws are shown in 24, A and B being triangular, with a moderate amount of radius at the roots, C, with a *gullet* tooth, while the horizontal machines use webs with double sets of teeth, placed in reverse fashion, D, to cut in both directions alternately.

Band-saws. Band-saws are necessarily very flexible, to lap around the pulleys, and endure the constant bendings and straightenings which go on, and the temper must be uniform throughout the blade, in order to avoid cracks and breakages. The sizes range from $\frac{1}{8}$ in. to 16 in. wide.

The most common shape of tooth is that at A in **25**, while other shapes are shown at B, C, and D, with a greater amount of radius at the roots. The pitch, or distance apart of the tooth-points, is greatly varied, according to the size of the saw and the class of work which it has to do. Thus an $\frac{1}{8}$-in. blade will have nine teeth to the inch, $\frac{1}{4}$-in. six, 1-in. three, and so on. The blades are made in lengths, from which bands of suitable size are prepared by brazing the ends together.

Tension of a Band-saw. The *tension* of a band-saw blade relates to a certain slackness of the centre, produced by a hammer, or by rolls, the effect of which is to cause the blade to bear on the pulleys with its outer edges, and not in the middle plane. The amount of tension varies for different saws.

Another point is that, to run properly, the back of the saw must be perfectly straight. A long straightedge is applied to test the accuracy or otherwise, and the matter put right by hammering or by rolling. Should the back be concave, the surface is



22. THIRTY-INCH BAND-SAWING MACHINE

worked over near the back with a series of blows extending to the central portion; if convex, the hammering must be done near the toothed edge. The necessary side-clearance of a band-saw blade in the timber is obtained either by forcibly setting over each tooth alternately to right and left, so that the resulting cut is wider than the blade itself, this being termed *spring set*, or by *swaging* the points of the teeth—that is, applying pressure to the front of the teeth, so spreading them sufficiently to clear the blade in the cut. This is the *swage set*. The latter is not quite so smooth cutting as the spring set, but operates quickly.

Circular Saws. Circular saws have teeth of very diverse types, the shapes of which depend upon the class of cutting, whether with or across the grain, and the relative hardness or softness of the timber. For ripping soft woods the teeth are spaced widely, and are formed more acutely than for the harder varieties. Figure **26** illustrates some of the commoner shapes of circular-saw teeth in use. A, B, and C are triangular teeth, with more or less rake, for softer woods; D has gulleted teeth, which afford great freedom for the sawdust. Two other shapes for ripping are shown at E and F. G is for ripping hard wood, the rake being lessened accordingly. Cross-cutting requires a different form of teeth, because, instead of passing down and forcing the fibres asunder, as with ripping, the saw has to sever the fibres at right angles, which imposes much more resistance. The shape of the tooth is that of an equilateral triangle, called a *peg* tooth, H, and it is bevelled to produce a keen edge, each tooth having the bevel facing in an opposite direction to that of the adjacent tooth. There is no hard and fast rule for the use of the peg-tooth, since some of the other previous shapes of teeth, notably D, are used freely for cross-cutting in the soft woods, but they are limited to these woods.

Inserted Teeth. The Americans have developed a class of circular saws with *inserted* teeth, which are used largely for diameters above about twelve inches. The advantages claimed are that a better class of tooth can be produced, as regards temper and clearance, than when the teeth are formed out of the solid plate, and also that in the event of nails or spikes being encountered in the timber, the damage to the saw is far less, because at the worst a few teeth are broken off or torn out without damaging the plate, and can be quickly replaced with new ones. But a solid-tooth saw under the same circumstances may have several teeth broken out, necessitating the reduction of the entire diameter to bring it down sufficiently to make a new set of teeth all around. The fitting in of the tooth is effected by vee edges, which prevent lateral movement, and the actual cutting portion or *bit* [A, **27**] is secured by a *shank*, B, the two wedging together firmly when slipped into place by the help of a special wrench, having a pin fitting in the hole in B. The shank is split in some cases to produce a decided spring, to retain the parts in place [**28**].

Special Saws. *Ground-off*, or *bevelled*, or *swaged* saws are tapered off in thickness from the centre to the edge, which may be very thin, while still leaving the body stiff. The grinding off is done only on one side. The result of thinning the saw thus is to save wood in the kerf, and to enable fine sawing to be done, so that these ground-offs are very suitable for fine cabinet and box work. The teeth of swaged saws are pitched rather closely together, and are smaller than those of ordinary or *plate* circular saws.

Hollow-ground saws are a class which work without set, the clearance being provided by grinding each face tapering from the teeth to near the centre, where a parallel portion is left for the spindle collars to grip. As the teeth are wider than the blade behind them, there is no side-friction. These saws make a very smooth cut, and are used for the finer classes of work, including mitre cutting.

Grooving saws are hollow-ground saws, made of definite thicknesses to cut grooves, ranging from $\frac{1}{8}$ in. to 1 in., or more. They leave a smooth surface. The teeth are coarsely pitched for good clearance.

Drunken Saws. Another class of saw employed to cut grooves or tenons is the *drunken* or *wobble* saw. The blade is held in an oblique position, so that it wobbles while revolving, or alternately travels from one side to another, so that when fed into the wood a slot is cut out. Bevelled washers are employed in some fittings to cant the saw. Figure **29** illustrates a saw by the Carron Company, Carron, Stirlingshire which has a ball centre, A, upon which the saw, bolted to a socket, B, embracing the ball, may be moved to give any required inclination within its range. B has a stud fitting in an inclined groove cut inside in the surface of a washer, C. The whole arrangement is firmly clamped by the nut, shown dotted, at the end of the spindle, and the saw cannot alter its angle until this nut is slackened.

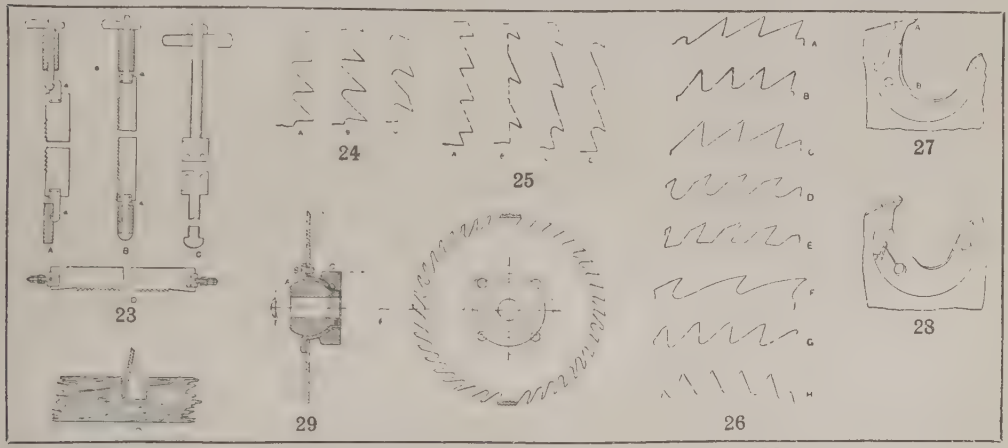
The diagram at D shows the action of the drunken blade in a groove.

A few other special saws may be mentioned, such as the *segmental* types, which have their blades built up of radial segments mounted on a central boss, by which device a thinner edge can be obtained than by using a solid plate. These are used for thin re-sawing work and fo. veneers. *Concave* saws are dished to form the envelope of a sphere, and are employed in cutting curved pieces, such as for wheel felloes and barrel parts. *Cylinder* saws, which are in the form of a large tube, with teeth on one end, saw out barrel staves to the correct curvature on one side.

Tension and Packing. The *hammering* of a circular saw is done to bring it into a proper condition for true running ; there may be tightness or *tension* at the rim or near the centre, according to the manner in which the hammering is done. The apparent rigidity of a saw plate disappears as it attains a high speed, and it becomes limp and pliable, and is very susceptible to lateral pressure. There is a certain critical speed for every saw, at which it will run true, if hammered

have occurred through sawyers getting their hands caught in the teeth, chiefly on account of the fingers slipping when feeding the stuff. One of the best-known guards is the "Ideal," constructed by Messrs. M. Glover & Co., of Leeds. It is so made that the saw is completely protected, no matter what the height of the wood being sawn.

Planing Machines. The *planing* machines constitute a large group, which operate by *cutters* or *knives*, either revolving or fixed. They true up narrow or broad surfaces, cutting on one or on several sides of the timber, and have hand or power feeds. The simplest class of planer is that represented in **31** (Messrs. John Sutcliffe & Son, Ltd., Halifax), termed a *hand* or *overhand*, or in America a *buzz*-planer. The frame carries bearings for a revolving spindle, which holds two or three long cutters revolving at a high speed, the spindle being driven from the belt pulley at one end. The timber is passed over the two tables projecting out at each end, and adjustable vertically upon sloping ways by screws and hand wheels. The fence on the right-hand table guides the wood in a straight line, and can be canted over for angular work.



23. FRAME SAWS **24.** FRAME-SAW TEETH **25.** BAND-SAW TEETH **26.** CIRCULAR-SAW TEETH
27 AND **28.** INSERTED CHISEL-POINT TEETH **29.** DRUNKEN SAW

accordingly, but if the speed is altered, or the saw becomes reduced in diameter through repeated sharpenings, in the course of time re-hammering is required. Another feature of great importance is the *packing*, which usually consists of hemp, plaited and packed in on each side of the plate, being supported by boxes or strips underneath the table. The object is to support the saw laterally, and enable it to stand up to the work without running out of truth, which it would do on encountering variations in the timber. There is another effect, that of imparting a certain amount of warmth to the saw plate, regulating the tension, and preventing buckling. The running of the saw can be controlled by packing harder or softer. Thus a saw that is "loose" on the rim may be made to run properly by packing rather tighter near the centre than towards the periphery, so that the central area is warmed up, and the metal expands more, pressing on the rim portion, and checking the unsteadiness. The packing is lubricated by some class of rather thin oil.

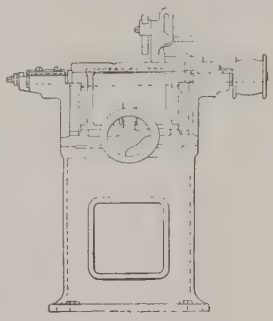
Saw Guards. The question of a provision of a *guard* to a circular saw has to be considered. It is a very dangerous tool, and many accidents

The two curved springs passing down the front keep the timber upon the table. In operation, the right-hand table is set lower than the left-hand one by the amount necessary for the cut, and the workman, standing alongside this right-hand table, passes the wood over it and the cutter spindle until the other table receives it. The machine is often termed a *jointer*, because one of its principal functions is that of preparing edges for glueing together. Planing out-of-wind, surfacing, chamfering, rebating, etc., can be done also, or, by putting in special cutter-blocks, mouldings and tongues and grooves can be produced.

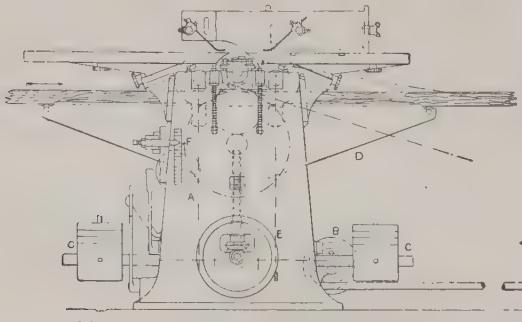
These planers are sometimes adapted to the requirements of wheelwrights by fitting curved guides at the front, to pass felloes over an extension of the cutter-block, and so to plane the inside to a regular curve. A boring and mortising attachment is also included when desired ; it is fitted similarly to that mentioned previously in connection with circular-saw benches.

The hand planer is one of the most dangerous machines to operate, because the knives revolve between the lips of the tables, and the attendant's fingers are very liable to slip into the opening

and become mangled. The safest class of work is that of shooting the edges of boards, in which case the hands are raised up to a considerable height from the knives. A safety guard, as applied to such planers, comprises a bridge spanning over the opening, its height being variable to suit the thickness of wood being planed, so that there is no chance of the workman's hands touching the cutters. If thin boards, etc., are being surfaced, the guard reaches across to the fence; but if edges are being planed, the guard is drawn away from the fence sufficiently to let the stuff pass, leaving the rest of the gap covered. The opening between the tables is made as narrow as possible in most machines by screwing thin tapered steel lips on to the table edges, projecting over the cutter-block as far as practicable.

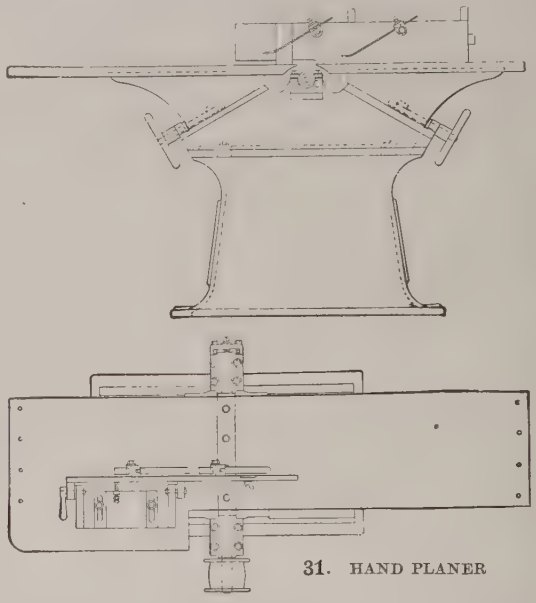


Surfacing and Thicknessing Machine. An advance on these machines is the combined surface planer and *thicknessing* machine [**30**], which has a power-feed by rollers, passing the timber through between the rollers and the cutters, and reducing it to an even thickness. One side of the stuff is previously trued upon the surfacer. The upper portion of the machine in **30** (by Messrs. McDowall) is formed like the preceding one; the arrangements for thicknessing include four serrated rollers, lying to right and left of the spindle, and passing the stuff between them, the upper rollers being positively driven by spur gears (the dotted circles of which are indicated), deriving various rates of speed from cone pulleys at A and B. Heavy adjustable weights at C, C, press upon levers which pull down the top rollers and enable them to get a bite on the wood. The table, D, supporting the latter, is raised or lowered by a vertical screw, operated by the hand wheel, E, and an index scale at F shows the thickness being planed. The arrows show the directions in which hand and power feed are given, these necessarily being in opposite directions, on account of working above and below the cutter-block respectively.



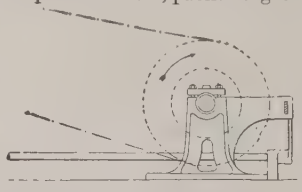
30. 15 IN. × 7½ IN. SURFACE PLANING AND THICKNESSING MACHINE

Trying-up Machines. Before describing other classes of planers which bear resemblances to those already illustrated, we have to notice a particular type of planer—the *trying-up* machine—which is adapted for truing up heavy pieces of timber. Such timbers are often too irregular and hard to pass through a roller feed with true results, so it is clamped to a travelling table and fed under the revolving cutters, leaving the planed face quite flat. The general form of the machine is represented in **32** (Messrs. A. Ransome & Co., Ltd., Newark-on-Trent), which shows the timber gripped on the travelling table, A, passing under the adze block at B (covered with a guard). The height of the adze block spindle is adjustable, by sliding it up or down the sloping housings, through hand, or belt, operating vertical screws. The driving of the spindle is by belt from the countershaft C, at the rear. The traverse of the table, with a quick return, is effected by belt pulleys behind the upright, actuating a train of spur gears, the last engaging with the rack on the under side of the table, A.



31. HAND PLANER

The machine is adapted not only for plain, large work, but can be used for truing and planing a large number of moderate sized pieces, such as the parts of doors, packed together on the table. Moulding and grooving can also be done by replacing the plain adze block with suitable cutters; and in machines provided with additional vertical side spindles, carrying cutter blocks, the edges of timber can be planed. A roller feed is fitted, when necessary, to the tables of trying-up machines for the continuous feeding of thin boards, which do not require to be clamped by the table dogs.



Panel Planers. The surface planing and thicknessing machines, or *panel* planers, which are used for all classes of boards and panels of moderate size, are constructed to pass the timber over a table, above which the cutter cylinder is revolving. The thickness is varied by altering the

height of this table. Another variety of these machines is the *two-side* or *double* surfacer, which has two cutter cylinders, one above and one below, so that a board or panel is finished at one operation.

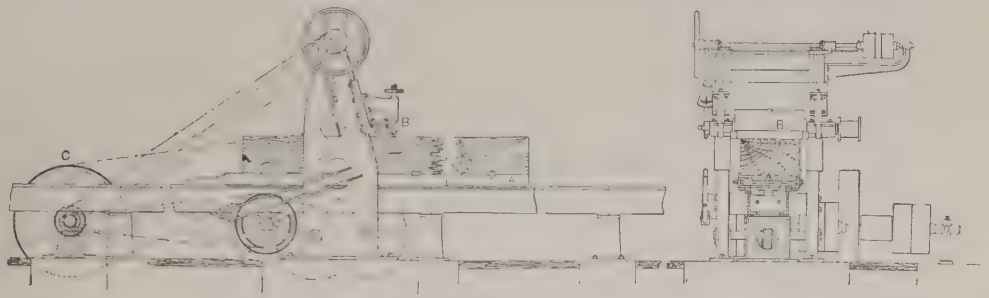
Four-cutter Planers. The most complete types of machines are those which work all four faces of the wood simultaneously—the *four-cutter* machines. These have the highest output, and a very good finish is imparted provided proper care is taken in working the machine. They embody a *fixed* knife in addition to revolving cutters, this knife giving a very smooth surface to the work. But as good results can be obtained only by feeding the stuff past the knife at a high rate, and as this demands great power, it is more convenient to use a fixed knife on one side of the wood only—the under side—working the other side and the edges with rotating cutters. In **33**, which gives a side elevation and end view of a 16 in. by 6 in. four-cutter machine for heavy work (A. Ransome & Co., Ltd.), the respective positions of the cutters are indicated at A, B, C, and D, these letters being put on the timber for clearness. The timber is fed in at the right-hand end, first by two pairs of large serrated rollers, driven by gearing, and weighted through balanced levers. On arriving at A, the wood is attacked by the bottom cutter block there, which trues the under side. Passing on to B, the fixed knife is encountered, this finishing the under side. A series of pressure rollers is placed above A and B, each roller being provided with an independent weight, so that any irregularity is accommodated. Other large feeding rollers at the centre of the machine continue to carry the timber on and past vertical cutter blocks at C, which plane or mould the edges, weighted pressure rollers keeping the wood down at this point. Finally, another horizontal adze block is met at D, finishing the top face. By means of the hand wheel, E, the operator can raise or lower the whole of the top feed rollers at once for timber of different thicknesses.

The fixed knife at B is rapidly dulled by its work, notwithstanding that the block at A has roughed off the outside of the timber, and it is therefore fixed in a removable drawer, that can be pulled out and changed rapidly. The fixed knife cannot be applied successfully to cutting hard woods. It is set angularly across the machine to give a shearing cut, and the pressure rollers above it are placed to correspond. An extra cutter spindle is sometimes added at the delivery end for *sticking* a light beading on the top of the plank or board. A *shavings cutter* is a useful adjunct to a machine having a fixed knife; it comprises a hopper containing revolving cutters, which cut up the long shavings into short portions, that can be readily sucked up by a pneumatic exhausting system.

Rapid Planers. The *lightning* or *rapid* planers are a special class, using a fixed knife only. The work is carried over it by a large roller covered with indiarubber, and the rate of feed is very high. The class of planing done is that on box boards, lap boards, blind laths, which are light, and which require only a thin shaving off to produce a highly finished surface.

Four-cutter Moulders. Four-cutter machines, designed for producing mouldings only, resemble the planers in many respects, but the fixed knife is not used. A good idea of a moulder can be obtained from the drawing [35] (John Sutcliffe & Son, Ltd., Halifax), showing a 16 in. by 4 in. machine in elevation, plan, and end view. The cutter block spindles are at A, B, and C for bottom, edges, and top respectively. The fluted feed rollers, situated under covers at D, can be driven at any of six different rates, from 18 ft. to 70 ft. per minute of feed, the variations being produced by sliding spur gears, as seen. The wood is held firmly to the cutters by weighted *pressures*, which can be adjusted to suit requirements. Combined planing and moulding machines are employed for either class of work, as desired.

The spindles of planing and moulding machines run at from 4500 to 5500 revolutions per minute, and the cutters must be very accurately balanced in order to produce true work and to avoid damage to the machine through irregular running. The bearings must also be good, with ample surface, and making a close fit without shake, which is fatal to accurate results in planing or moulding.

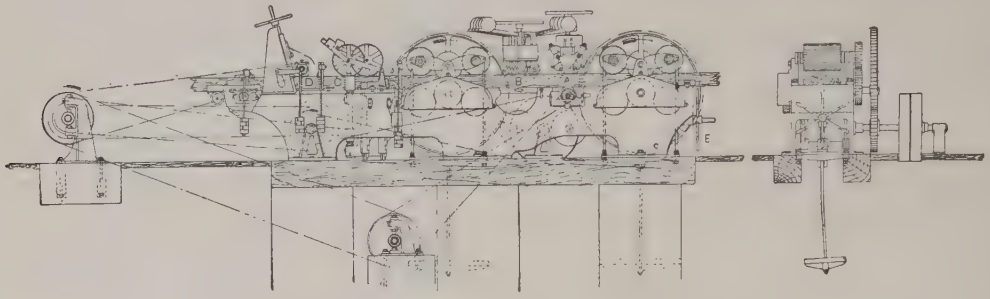


32. 20-IN. TRYING-UP MACHINE

Vertical Shaper. The *vertical* spindle moulding machine, or *shaper*, has either one or two spindles, projecting up through a table, on which the work is laid. The spindle carries a moulding iron, and as the work is traversed past it cuts the surface into a form corresponding with that of the iron. A fence guides the wood in a straight line. Figure **34** shows a double-spindle machine by Messrs. Thomas White & Sons, Paisley, from which it is seen that the spindles, A, A, have long pulleys driven by half-twist belts from the countershaft. Each headstock carrying its spindle is adjustable up and down in slides, the adjustment being obtainable by turning the hand wheels at the front. The treadle in front, near the ground, enables the operator to start and stop the machine by slipping the belt on the fast and loose pulleys at the countershaft. Concentric rings are fitted into the table around the spindles, to allow of putting on differently sized cutters. The object in having two spindles is to enable curvilinear work to be done expeditiously, by using one or other of the spindles, which revolve

in opposite directions, according to the way which the grain runs; otherwise, clean work cannot be ensured. If the machine has only one spindle, that has to be reversed, and a different cutter block also put on, or else doubled-edged cutters are used. The working of curves is effected by using a template of the correct outline, placed beneath the moulding, and bearing against a ring encircling the shaper spindle. The template can often be dispensed with and the moulding alone brought into contact with the guide-ring, or collar. It is best simplest of which are those for plane surfaces, having flat knives bolted to the sides of a cylinder or block in the manner shown in **57** [page 4245], the length ranging from a few inches to two or three feet. Moulding cutters are also made as shown at **56** on that page.

The vertical spindle-moulding machines uses a variety of cutters. In the *French* or slotted spindle a thin steel blade is fixed in a slot in the spindle end, and, its edge being formed to correct outline, it is turned over forcibly like a scrape to produce



33. FOUR-CUTTER PLANING MACHINE

to fit a guard over the revolving cutter, as a protection to the operator. A cage made of strips, or of netting, completely covers in the top and the sides as far down as the work will allow. There is then no risk of the workman getting his fingers caught through the wood slipping.

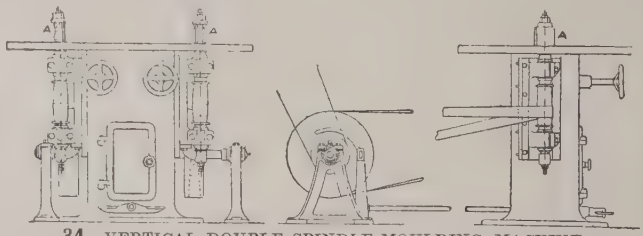
A special attachment for cutting dovetails is often fitted to these shapers, comprising a clamp, which holds the wood vertically, and presents it to the dovetail cutter on the end of the spindle. The pitch of the dovetails is determined by a template plate, having notches which lock the clamp at definite positions while the cutter is at work.

Another class of moulding machine, which possesses a greater range than the foregoing, is made with an overhanging arm supporting a vertical spindle, below which a large table is located. In this design the work can be passed *under* the tool, and operations be done on the central portions of a board or panel, such as raising or recessing various patterns, cutting grooves or trenches, in string boards for stairs and shelves. The table can be moved about freely, and is fitted with fences.

In the most complete machines a vertical shaping spindle is included, projecting up through the table, by which ordinary mouldings can be worked. The term *variety* moulding machine is commonly applied to this class.

General Joiner. The *general joiner*, or *universal* joiner, or *complete* joiner, is a combination machine of great utility in situations where a number of separate machines cannot be installed. It combines a circular saw, with rising and falling spindle, with which sawing, tonguing, grooving, and rebating can be done; a band-saw apparatus, a four-side planing and moulding apparatus, a vertical spindle for circular moulding, and a tenoning apparatus. Boring may be done also by attaching a bit to the tenoning spindle.

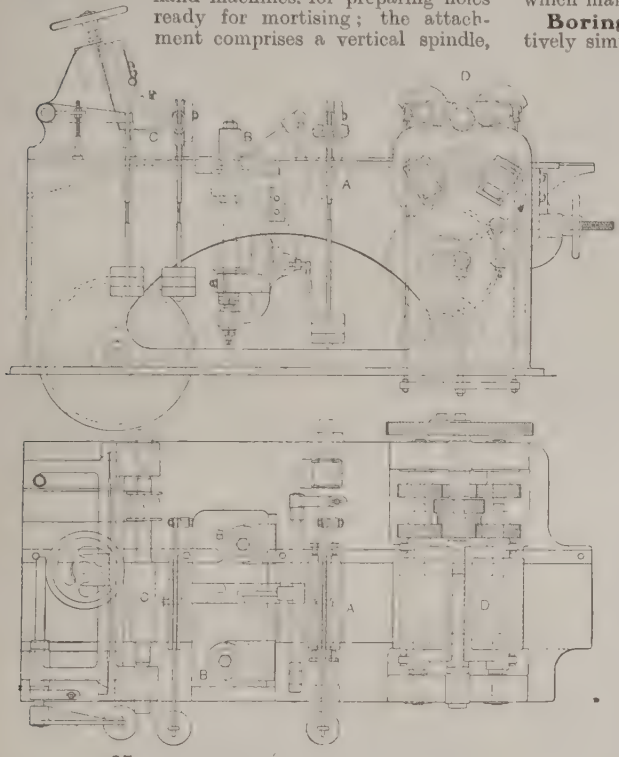
The cutters and cutter-blocks employed in the planing and moulding machines described in the previous article embody numerous shapes, the a working edge. The French cutters are used chiefly for special classes of work, as the blades can be made cheaply and quickly. A common method is to fit flat cutters between grooved collars, as illustrated in **34**. Sometimes also an ordinary square block is fixed to the spindle end, to receive flat moulding cutters. Solid cutters bear some resemblance to milling cutters for metal, in having the moulded outline formed on the circumference. Sharpening is done on the flat between the teeth. The non-reversible types have a clearance in one direction [**36**]; the reversible class are flatter on the periphery [**37**], so that either edge may come into operation as the machine spindle is reversed. Four, eight, or ten cutting edges are produced, according to whether the cutters have two, four, or five teeth [see **58**, page 4245]. Figs. **38** and **39** illustrate their application, the first showing the use of the work itself to press against the guide collar under the cutter, the second that of a separate pattern plate to which the moulding is attached.



34. VERTICAL DOUBLE SPINDLE-MOULDING MACHINE

Mortising Machines. These, which are intended for cutting the slots or mortises in timber, are of vertical or horizontal types, the latter chiefly for light work. The commonest method is to use a chisel [**40**], resembling a hand mortising chisel, but held in a spindle, and fed down by hand or power. An improved form in general use is the *self-coring* type [**41**], which has two projecting lips, which, being tapered inside, have the effect of drawing the chips from the mortise at each stroke, thus keeping the hole clear. Figure **42** shows a

plain hand mortising machine, by the Carron Company, in which the timber is gripped in a vice by a hand wheel and screw upon an upper slide, which can be moved longitudinally by rack and hand wheel, and also laterally, while vertical adjustment is produced by the screw and hand wheel beneath the knee. The spindle, which fits within a sleeve sliding in a hexagon bearing, is reciprocated up and down by the long pivoted lever, counterbalanced to bring the spindle to the top of its stroke automatically. A handle and collar is fitted on the spindle, by means of which it can rapidly be reversed, to make the chisel face round in the opposite direction for finishing both ends of a mortise. A boring attachment is often fitted to hand machines, for preparing holes ready for mortising; the attachment comprises a vertical spindle, carrying an auger, revolved through bevel gears and handles.

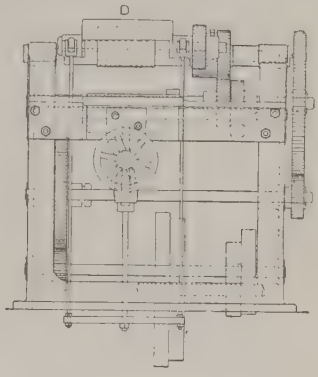


35. FOUR-CUTTER MOULDING MACHINE

A peculiar class of tool used for mortising comprises a combination of an auger and a chisel, the former revolving inside the latter, and clearing out the centre of the hole, while the square corners of the chisel finish the angles. This, the *hollow* chisel [43], is used in both vertical and horizontal machines, and is very rapid and neat in its action. The auger, which has a support near the cutting edges of the chisel, draws the chips out of the hole and away through the openings in the side of the chisel. Another remarkable style is the *chain* mortiser, which runs an endless pitch-chain around a sprocket wheel and a plain roller, while the back is supported by a flat bar. Each link of the chain has a tooth formed on it [44], so that as the chain travels it cuts a slot equal to its width. The rate of movement is about 1500 ft. per minute. The chips are drawn out of the mortise on the rising side of the chain. The work is done with great rapidity, and the tendency to split the wood is not nearly so marked as is the case with a reciprocating tool.

Tenoning Machines. Tenoning is performed by cutter blocks or by tenoning irons. The first-named operate laterally, and the machines which use them have two spindles, above and below the timber, both driven from a single belt, which is provided with a tightening jockey pulley. The cutter or adze blocks have their irons set on the skew, and have provision for cutting the shoulders on the timber. The timber is clamped to a carriage which runs by rollers on cross-rails. In cutting double tenons, a vertical spindle is required on the machine to carry a drunken saw, or a narrow cutter-block, which makes the centre cut.

Boring Machines. These are comparatively simple in construction. Spindles are single or multiple; the plainest class is the wall or pillar machine, which consists of a framing supporting a spindle, a sleeve, mitre gears, belt pulleys, and a lever arrangement for feeding. The self-contained machines include a pillar, on the front face of which the table is adjustable up and down to suit the thickness of the work. The multiple spindle machines embody a number of spindles, each holding a different-sized auger, so that any size hole within the range can be bored without the trouble of changing tools. The railway carriage and waggon shops especially favour these machines for boring the heavy framings. In some instances the spindles may be angled for boring sloping holes. Horizontal boring machines are used to much less extent than vertical ones, being chiefly designed for small work, such as boring dowel holes in the edges of boards. The augers used in the machines described are of the usual twist types, some of which are illustrated in **41** on page 4245.



Dovetailing Machines. Dovetails are usually cut by revolving cutters, having two lips, and a body the form of which corresponds to the tapered outline of the dovetail. In the single spindle machines the timber is clamped and moved along in definite stages, controlled by a slotted driving plate matching the pitch of the dovetails. But a much greater output can be secured by increasing the number of spindles, to cut all the dovetails in one side of a board at one traverse.

Corner locking is practised very largely in place of dovetailing, and consists in forming rectangular teeth which interlock and hold very firmly. As the form

of cut lends itself to very rapid output, a good deal of box and case work is now corner-locked instead of dovetailed. The machines employed have a table on which the work, which may include a pile of boards, is clamped, and a revolving spindle holding a number of narrow cutters attacks the edges and cuts out the series of notches.

Lathes. An ordinary turning lathe is illustrated in **45**. Here we only concern ourselves with special types, which are designed for repetition work. The *Blanchard* or *copying* lathe produces objects of regular or irregular shape from a pattern or copy. Gun-stocks, spokes, hammer-handles, boot-lasts, brush-handles, etc., are among the chief pieces turned out. The principle is that of rotating the copy and the work, and causing a roller to press against the copy, thus coercing a rocking rest which carries a revolving cutter head in contact with the wood. The contour of the copy is therefore reproduced on the work.

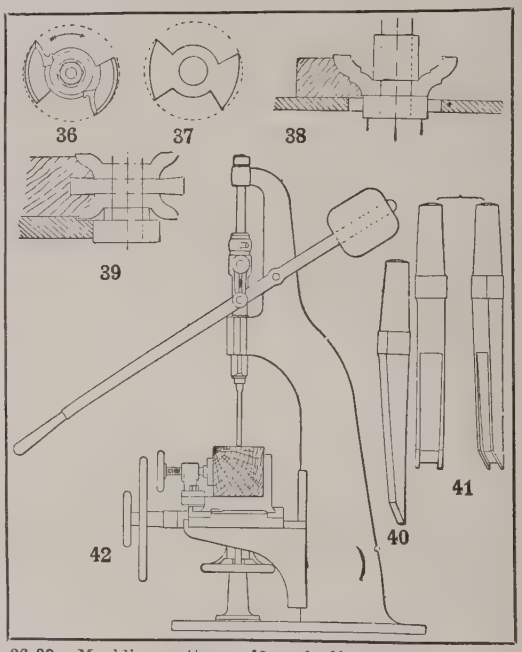
Back-knife lathes are a class for producing circular work of varied contour, such as chair and table legs, balusters, etc. The tools are held in a rest, and controlled by a pattern; the back knife is held in a frame in a sloping fashion, and the movements of the slide-rest and the knife are timed so that the latter comes down the back of the work and finishes it to correct outline as the roughing tool passes along.

The *rounding* machines perform a plain class of turning by very simple means, comprising a revolving mandrel carrying a cutter, which acts on the stuff, which is simply slid through.

Sandpapering Machines. These include the use of drums, discs, and belts, each suited to particular classes of work. The belts are run over pulleys, which can be drawn apart to give the required tension. Articles having curved outlines are treated on the belts, which give to the conformation and enable curves and hollows to be treated. The drum machines are of two types—one with a flat table, over which the work is passed, touching the drum surface; an exhaust fan removes the dust as fast as it is created. The other drum type has three drums, over which the wood is passed by eight geared feed rolls. Each drum has a side oscillating motion to prevent the formation of scratches. Small sanders with vertical spindles are constructed on the lines of the vertical shapers. Disc sanders resemble the disc grinders used by metal-workers, and the work is presented upon a table to the disc. For large areas the *flexible* arm machine is of great value. The sandpaper is strained over a wooden disc, supported at the end of an articulated frame, which, by virtue of its jointing, can be brought anywhere over a large table.

Wood-turning. The craft of wood-turning is very ancient. It was formerly done by a reciprocating mandrel, operated by a bow and cord; or by an overhead spring pole, operated by a treadle. The bow and cord still survive in the East. All modern wood-turning lathes are fitted with continuously running mandrels. Lathes for woodwork are much plainer than those for metal turning, seldom comprising more than a plain ungeared headstock, a simple poppet, and a hand tee-rest. For some engineers' pattern turning, a plain slide rest is fitted and a large face-plate, or a special face lathe. But with these exceptions, and that of the ornamental turner, wood-turners' lathes have no aids to supplement the work of the hands. The fact is, a skilful turner is more nearly independent of his lathe and tools than most craftsmen, and excellent work is done by such men on lathes that would excite the derision of the engineer or the wealthy amateur. Wood-turning is one of the crafts in which manipulation is the supreme factor, one in which the essential tools are few and very simple in character.

A large, high-class lathe, much superior to those usually found in wood-turners' shops, is shown in **45**, made by T. White & Sons, of Paisley. It is all of iron, while wood figures largely in much lathe construction. It is of large size, 12-in. centre, designed for pattern turning and general utility. The following are the principal parts: the *bed*, A, having at one end the *headstock*, B, with the four-stepped cones, C, turned inside and out for perfect balance, and driven from the cones, D, on the



36-39. Moulding cutters **40** and **41**. Mortising chisels **42**. Hand mortising machine

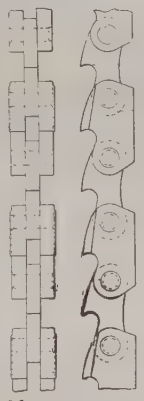
countershaft, fitted with fast and loose pulleys. E is an iron *face-plate*, to which work can be screwed directly, or through an intermediary plate of wood. F is the *fork*, or *prong* centre. G is the *loose poppet*, or back poppet, or movable poppet, or loose head, and its centre is the *back* centre. It is fitted for turning long tapers, as on columns, by utilising the cross-traverse movement provided. The tool rest commonly used is the *tee-rest*, H, with which nine-tenths of woodwork is done. But for long pieces, a *slide-rest*, J, is provided, comprising the tool holder on a cross slide, adjustable across the top of the saddle, which is fitted to the bed with vee'd edges, and an adjustable strip. The saddle is travelled up and down the bed by a rack, K, the pinion of which, L, is actuated through a pair of gears, N and O, by the lower lever handle, M, the upper handle being for the cross traverse. A nest of drawers, P, is formed underneath the bed to receive the tools, and a rack, Q, adjacent, receives face-plates. R is the *back board* for tools in use.

Wood-turning Tools. The principal operations are performed with two tools only, the *gouge* [**50**] and the *chisel* [**51**], each being used in three o

four different sizes. Both are true cutting tools, both require practice and skill in their manipulation, and all conceivable shapes are outlined by deft handling of these two. True, there are many others which complete a turner's kit, but they are only used for occasional finishing, smoothing, and correcting. All the roughing out, and by far the greater portion of the finishing also, are done by these two very simple tools. We will consider them and their work in turn.

The Gouge. This [50] is like no other gouge. It has a considerable convexity of the cutting edge, the reason of which is to prevent, or to lessen, risk of hitching or catching of the revolving work against one corner of the tool, which would happen if an ordinary firmer gouge were used for turning, or if the gouge were ground like 46, instead of like 47. It is this rapid revolution of the work, with the centrifugal action, tending to knock the gouge away, that the turner, consciously, or instinctively, born of habit, always has to bear in mind. The beginner, after sundry hitchings, and damage to the work, his hands, or the tool, or all in unison, soon learns to present the gouge warily. The thing to remember is not to allow the work to catch in the sides of the gouge, but to do the cutting at and near the point *a* only. Bearing this in mind, faces that are perpendicular to the axis of rotation can be roughed down safely, the back of the gouge being held next the face being cut. Concave and convex portions are also easily cut, the back of the gouge always lying next the face being turned.

43. HOLLOW CHISEL



44. MORTISING CHAIN

When turning a parallel, or straight portion, the gouge can be held straight forward [52]; but, generally, more rapid reduction can be effected by turning with a diagonal cut, or sideways, changing the direction of cutting towards right and left alternately. Deeper cutting can be done by this device than by straightforward presentation, though the latter is suitable for taking finishing cuts. To suit details of work of different dimensions, gouges are made in different sizes, from $\frac{1}{4}$ in. to $1\frac{1}{4}$ in., so that either fine details or heavy roughing down can be done by selecting suitable gouges. The *handles* of these gouges [49 and 52] will be noted as being characterised by much leverage. To this, in fact, they owe so much of their value. The workman is thus able to control their movements in opposition to the severe stresses caused by the revolution of the work. A firm grip is taken at the fulcrum—that is, the place where the gouge lies on the rest [52]. The gouge is gripped there between the forefinger and thumb of the left hand, while the end of the handle, gripped in the right hand, is kept in constant movement in arcs of circles to suit the nature of the cutting being done. In some cases the side of the gouge is presented, as in taking a finishing cut in a bore [49]; 53 is a gouge used on the slide rest.

The Chisel. This [51] is the only turning chisel with a doubly bevelled edge like that of the axe, though used in quite a different manner. It is presented and traversed against the revolving work, cutting shavings at and near the obtuse-angled end. The degree of pressure exercised is controlled by the hands of the workman. The tool is gripped on the rest [59] by the forefinger and thumb of the left hand, similarly to the gouge while the right manipulates the handle. Like the gouge, the chisel will turn straight and convex portions, though not concave ones, unless of large radius. The point to observe is that cutting must not be done far away from the point, *a* [48], and, say, over one-third of the width from the point, otherwise the tool is liable to be caught, and damage the work. It can be used indifferently in right and left directions [55]. The chisel, like the gouge, if used properly, leaves a very smooth surface. The acute-angled corner of the chisel fulfils the special function of cutting down perpendicular or nearly perpendicular faces [58], and of severance. Being so keen a wedge, it will cut deeply and rapidly, leaving the smoothest face. It cannot be used for turning like the other angled corner, but would be caught by the work if presented thus.

Scraping Tools. Though the gouge and chisel are the sheet anchors of the turner, it is obvious that they cannot cover all details of work, and especially in pieces of large dimensions. Thus, a disc on the face-plate cannot be turned and finished with the side chisel. For this a *firmer* chisel, acting as a scrape, must be used. A deep hole can be roughed with the gouge, and partly smoothed with the keen edge of the side chisel, but a true, smooth face must be finished with a *side tool*. A concave portion can be roughed with the gouge, and is often finished with it; but frequently it is finished with a *round nose*, especially in work of large diameter. These and some other tools act by scraping only. Hence, as scraping roughens up the grain, the object always sought is to do as much preliminary work as possible with the gouge, and take the merest film off with the scraping tools.

Hard and Soft Woods. The relative utilities of scraping differ in the practice of turning hard and soft woods. It is done much more extensively in the first named than in the second. The reason is that the grain of hard wood does not become roughened up nearly so much at that of soft timbers. This, of course, is not an argument in favour of scraping, when turning can be done by the gouge and chisel. But when work is of a highly ornamental character, and of large dimensions, as in much of that done on the face-plate, the risks of hitching are lessened by the use of scraping tools. The harder the wood, the more nearly the conditions approach to the turning of the softer metals. Thus, Spanish mahogany is harder than baywood, and lignum vitæ or box is more suitably scraped than beech or birch. Also, dry, well-seasoned woods can be more readily scraped than moist and spongy stuff. So that there is room for exercise of judgment. When details have to be turned to exact dimensions the scrapes are valuable aids, because very minute amounts can be removed by their assistance, and further finishing may be avoided.

The hardwood turners, therefore, have a large assortment of scrapes for turning concave and convex portions, for recessed work, right and left handed, besides special forms of tools for internal shoulderings, etc., in some of which it would be quite impossible to use the turning gouge or chisel.

All turned work may be classified under two heads —that done *between centres* and *chuck work*.

Work between Centres. This signifies that the piece to be turned is supported and revolved between the fast headstock and the loose poppet. It includes all pieces the length of which exceeds the diameter by so much as to require support besides that afforded by the headstock. Generally, such pieces are held and rotated by the fork or prong centre [**51**]. This is interchangeable with other chucks on the mandrel nose. It derives its name from its fork or prong like character. The end of the wood, if soft, is driven against it, or, in hard wood, a saw kerf is often made to receive it. The back poppet centre is entered readily by screwing up the mandrel slightly. Occasionally other chucks are used to drive work between centres, but in most instances the fork is employed; **65** shows a piece of wood roughed out with the axe preliminary to turning.

Chuck Work. This signifies that pieces are held at the headstock end only, and without other support. Pieces the length of which does not greatly exceed the diameter or which are of less thickness are turned thus.

Face-plates. These are the principal chucks. They differ from those for metal turning in their greater simplicity, comprising only two forms, in a range of dimensions. One is the *screw point chuck* [**57**]—that is, the work is held on it by a central, short, tapered screw, having a coarse thread. This is sufficient to hold a small piece of wood—say, not exceeding 4 in. or 5 in. in diameter. Thick blocks —say, above 3 in. or 4 in. diameter—are generally secured in addition with a couple or three wood screws put in from the back of the plate.

Large Face-plates. These [**60**] have countersunk holes for the attachment of work by wood screws inserted from the backs of the plate. They are made in as large a range as the capacity of the lathe will admit. For very large face work, lathes are made either with a deep gap in front of the headstock, or the headstock is made to turn round through 90° or 180°, so that work can be taken as far down as the floor. In such cases a special rest is rigged up on a heavy *floor stand*, sufficiently massive to remain steady under the stress of turning. In many cases the trouble of reversing the headstock is avoided by carrying the mandrel out at the rear to hold the large face-plate, so that it is always ready for use. Pattern-makers, as well as wood-turners, use these face lathes for wheel-work of all kinds.

Wooden Plates. The face-plates are made of iron, except in the very small sizes—say, under 4 in.—for which brass is commonly used. But a large proportion of turners' work, and much the largest in pattern turning, is done not on the metal plates directly, but against an intermediary plate of wood screwed to the metal. The advantages are these: The wood plate can be faced up truly, while the metal plates often run slightly out of truth, due to wear on the thread. Turning can be done right up against the wood without inflicting damage on the tool edges. There is a slight elasticity in the wood, noticeable when turning, by comparison with turning done close down to the iron. But the principal advantage is that the wooden plates can be recessed to receive work for re-chucking centrally, often, too, without using screws, the friction of the work in its recess—or over a check standing out, in the case of chucking by a hole—being sufficient to retain it in place for light turning. In time, as a face-plate becomes turned down thus, a new one is substituted. Small plates are made of solid stuff, but those over 12 in. to 18 in. diameter are built up, the plainest with patterns, the largest with a cross and diagonals [**56**]. Much work is chucked, not directly on the plate, but blockings screwed to it. The reason is that plates of several feet in diameter are rather expensive, and would soon wear out if frequently recessed. The face is therefore retained plane, and chuckings are done on temporary blocks screwed to the face. This is done in large gear wheels, pulleys, and various rings.

There are some classes of turned work in which it is undesirable or inconvenient to insert screws, yet which must lie against a flat face-plate. Then *paper joints* are useful. These are adopted extensively in pattern turning, and it is surprising how great a mass paper will hold. Newspaper is suitable. It is glued on both sides, one side going next the plate, the other receiving the work. On large pieces, narrow strips of paper at intervals are sufficient; pieces of a few inches diameter may be carried with one piece of the same diameter. The joint is broken after turning by lifting the work with a chisel inserted in the joint, when the paper splits in two.

The Bell Chuck. The bell chuck is termed the *cup chuck* [**61**], and is used for some classes of work too small or too long for the face-plate, and also for pieces which have to be bored, or for objects that have to be turned and cut off in succession [**61**]. Boxes, egg-cups, vases, are examples of the first; drawer-knobs and cord-pulleys of the second. The wood is driven into the cup and holds by friction alone. The chuck is usually of brass.

There are many very delicate objects which will not bear any driving into the bell chuck, or into a wooden chuck driven into the bell, and recessed to receive work. For such objects the *spring chucks* are valuable. These are made generally in a hard wood, box being the best; sometimes also in brass. The body of the chuck, slightly tapered outside to receive a ring, is split by several saw kerfs cut radially nearly to the bottom of the chuck, and the metal ferrule is made to compress the body round the work by tightening it down the tapered body. Turners make these in several diameters.

Methods of Measuring. The diameters of turned work are mostly taken with common calipers. When large numbers of similar pieces have to be done the calipers are often fixed with a thumbscrew. A sizing tool [**62**] is also used with a guide at the back, for repetition parallel turning.

Dimensions in the longitudinal direction may be taken with a rule; but when quantities are done a strip is generally used, having the various lengths marked across it, whence they are transferred to the work. In such cases the piece is roughed out approximately parallel to the largest diameters, and the lengths set off on the rotating piece. Then these are set in with the keen angle of the side chisel down to the various diameters, which are turned, and checked by the calipers. Every portion is first turned as a parallel section, after which the different moulding sections are shaped with the gouge and other tools. Compare **63** and **64**.

Templets. These afford much aid to calipers in repetitive work. They are cut from a thin strip of wood and tried upon the work [**63**] from time to time as the final corrections are being made. A little chalk or red lead may be rubbed on the edge, to indicate the localities where contact takes place.

Straight Shafts. When a long portion of turned work is to be perfectly straight, as in the shafts of columns and pillars, and in pattern pipe-

turning, much time may be saved by first turning down at each end and in the centre to the correct diameter, and then planing a flat along from end to end, forming a tangent to the diameters. This, being chalked or red-leaded, becomes a guide to rapid reduction of all the intermediate portions, which can be turned almost to size without stopping the lathe. It is then easy to finish with a side chisel, and correct, finally, with a firmer chisel.

Steadies. When long, slender pieces are being turned between centres, they wobble, and cannot be turned truly without support intermediate with the centres. These steadies are very plain by comparison with those used by metal turners. Sometimes a rigid rod only is wedged between the ways of the bed, to be kept in contact with the back of the work; but generally a block of wood or an iron bracket is bolted to the bed to carry either a vee-block or to receive semicircular blocks. A single vee-block will cover a moderate range of diameters, but semicircular blocks will fit only one side. The practice is to turn down a portion to the correct size, somewhere about the centre of the length; grip that with the steady blocks, and then proceed with the remainder of the turning. In very flimsy work the steady is shifted to two or three successive positions, or more than one steady is used. Lubrication is necessary, or the friction between the work and the steady will cause smoking, and char the wood. If a lathe has a slide-rest, then a travelling steady which follows the work behind the tool can be used.

Square Turning. The principle of this is illustrated in **66**. The articles to be turned are arranged round the periphery of two or more discs, which are driven between the centres, driving with a face-plate at one end attached to its disc, the other end being supported on the back centre. The pieces of wood are attached with screws, the lengths being in excess of the finished article, to allow of the portion with the holes to be cut off subsequently. It is not necessary to fill in the spaces between the pieces with a view to prevent breaking out of the grain by turning, but those who are not skilful in the use of the tools glue strips in, as shown at *a* in **66**. The blocks, A, in the illustration are simply distance pieces, by which the end discs are retained rigidly. Of course, the larger the diameter of the ends, the less will the slight curvature due to the radius be in amount, and generally such ends would have to be framed up with a cross and segments. After the faces have been turned corresponding with one position of the articles, they are turned round and rescrewed in successive fresh positions.

Ornamental Objects. The work of the geometrical turner requires special high-class chucks and a special lathe. But very beautiful, effective ornamentation can be produced by the plain wood-turner by the repetition of similar figures, such as those shown in **63** and **64**, and allied forms, for there is no limit to the possible combinations of curves and straight lines.

J. G. HORNER

A STATION FROM WHICH WIRELESS MESSAGES ARE SENT ACROSS THE ATLANTIC

THE WIRELESS TELEGRAPH STATION OF THE MARCONI COMPANY AT CLIFDEN GALWAY

The Receiving Apparatus and Aerial. Detection of Signals. Detectors. Einthoven Galvanometer. Brown Relay. Portable Sets. Wireless Compass.

RECEIVING STATIONS

In the previous chapter methods were described of producing the electromagnetic waves which travel outwards from the aerial or antenna, and form the means of establishing communication. We have now to see how these waves are intercepted at the receiving station, and to deal with the various parts of apparatus essential to "picking up" the signals.

Resonance. How a receiving circuit will respond to a transmitting circuit can be seen from the experiment represented diagramatically in **15**. Here L_1 is a Leyden jar excited by an induction coil, so that sparks cross the gap, G, and L_2 is a similar Leyden jar, the inner and outer coatings of which are connected by wires, the contact of which can be varied at K. When the capacity and self-induction ($L \times C$) of the Leyden jar L_1 circuit setting up the waves is the same as that of the jar L_2 circuit (the *tuning* being effected by sliding K up and down until the self-induction of the wire and the capacity of L_2 is the same), a responsive spark will fly across a gap, F, made between the outer coating of L_2 and a piece of tin-foil, T, nearly touching it and connected with the inner coating. In other words, when the two circuits, sending and receiving, are in resonance, electromagnetic waves sent out from L_1 will excite oscillations in L_2 and cause a spark at F.

The Receiving Apparatus. In actual practice the current produced in the receiving circuit is infinitesimal, and instead of producing a spark it is made to excite a detector, which is described later. It will be convenient if we first study a simple receiving apparatus, shown in diagram form in **16**.

A represents, as usual, the aerial or antenna, and E the earth. They are connected by a coil of thin wire, J_1, acting as the primary of a very small induction coil, which induces an oscillating current in the secondary coil, J_2. This coil is placed in series with a condenser, K, and shunted on the condenser is the detecting device, D, and a sensitive telephone, T. If the circuit comprising aerial, coil J_1, and earth has the same capacity and inductance ($L \times C$), or a simple multiple or sub-multiple of the capacity and inductance of the transmitting circuit, it will be in resonance with it; and when the electromagnetic waves reach the aerial, oscillations will be set up in this circuit, which will induce oscillations in the secondary circuit, including J_2 and K. These alternating currents will cause vibrations in the telephone, T, producing a buzzing sound audible to the ear.

The simplest form of receiver would be one in which the aerial was of exactly the same dimensions as that of the transmitting apparatus, but this, of course, would be impossible in general practice. Consequently, if the aerial is too short to be in resonance naturally with the transmitting circuit, we add to it a certain number of turns of wire represented by J_1. Sometimes it happens that the aerial is too long, and in such a case a condenser is placed between the aerial and earth at the point C, shown in **16**.

In the majority of amateur wireless stations a transformer is used consisting of one coil only, with sliding contacts, as shown in **17**. Here the turns of the tuning coil, *ab*, represent the primary of the small transformer, and the turns, *cb*, the secondary winding. A very small condenser, K, often termed a *blocking condenser*, is used, and on this is shunted the telephone, T; *a* and *c* are sliding contacts, so that the number of turns in both *ab* and *cb* can be varied in order to tune up the circuits. For not only must the capacity and inductance of the aerial and earth circuit respond to that of the transmitting circuit, but the capacity and inductance of the small secondary circuit represented as within the dotted line must respond to the aerial and earth circuit.

The Receiving Aerial. The receiving aerial is thus connected to the primary of the oscillation transformer or jigger, the other end of the jigger being connected to a plate buried in the earth. A good earth connection is very necessary; and although for small stations a domestic water-pipe usually answers the purpose, in large stations, as we noted in the last chapter, a number of copper strips buried in the earth, with as large a surface as possible, or even galvanised iron sheets, are employed. In the case of a ship the hull of the ship, or any metal part of the vessel, is used, as this is in direct contact with the water, and forms an ideal earth. If a condenser is placed between the earth and the lower end of the jigger winding, it must be of the variable pattern, so that the capacity can be varied at will. The jiggers used are of various patterns; the primary is generally of thicker wire than the secondary, and has fewer turns, and both are wound on wooden or ebonite frames.

The receiving aerial has a certain amount of capacity, and the larger it is the better. The primary coil of the jigger supplies further inductance, and the two have together a natural time period of electrical oscillation. When the secondary of the jigger and the small condenser are in tune with the antenna circuit, the oscillations set up in the aerial have their energy transferred to the secondary circuit, and there is thus produced in the receiving apparatus a replica on a feeble scale of the actual oscillations set up by the transmitting circuit.

Detection of Signals. These currents are exceedingly small, in a fairly large station often amounting only to small fractions of a micro-ampere ($\frac{1}{1,000,000}$th of an ampere), and to be able to render their detection possible is in reality very wonderful. Minute as the currents are, they appear to be capable of producing heat; in fact, the micro-ammeters used to measure the currents received are often dependent on the heating of a fine wire. One effect of these minute oscillatory currents is to render a bad electrical contact good, and on this property is based the *coherer*, the first detector used for commercial work, but now completely superseded by more delicate and reliable apparatus. In Fig. **18** is seen a small glass tube, having had

the air exhausted so as to produce a vacuum. The terminals, T T, are each connected with a silver plug, S. These plugs are placed near together, and between them are a few nickel and silver filings. The filings cause the contact between the silver plugs to be very bad, yet when an electrical oscillation passes through them the contact is improved to such an extent that a current of electricity can pass through the coherer. In early wireless work this weak current was passed through a relay [see page 4467], and the relay, when actuated, worked a Morse inker, so that the dots and dashes of the Morse code were actually printed on a strip of paper as recorded.

The objection to the coherer is that after each oscillation has passed through it it has to be "decohered" by means of a tap or knock, in order to shake up the filings and render them again non-conductive. This entails special apparatus which is not always easy to adjust. Moreover, the coherer is particularly easily upset, or actuated, by atmospheric discharges of electricity, which produce the same effect upon it as wireless oscillations.

The Magnetic Detector. A great advance was made when Mr. Marconi introduced the *magnetic detector* [26], which has as its outstanding feature remarkable reliability. This detector is sensitive to wireless oscillations, and produces in a suitable telephone receiver a buzz of long or short duration in accordance with the length of the signals transmitted. It consists of an endless "string," made of fine iron wires, which passes round two moving wheels or pulleys actuated by clockwork. In its motion the string goes close to two magnets, with their north poles together, as shown in **19**. The particles of iron in the soft iron wire string become themselves small magnets under the influence of the lines of force of the magnets, and as the band is moving the string drags the lines of the force along in the direction of its motion.

The oscillating currents from the aerial and earth are passed through the coil, A, and they cause this lag in the magnetism of the iron band suddenly to disappear. A second coil, consisting of a much greater number of turns of fine wire, B, is wound over the coil, A, and connected to a telephone receiver, and the sudden change in the magnetisation of the iron band or string induces a current in the secondary, whose terminals, T T, are connected with the telephone receiver. A vibration of the diaphragm in the receiver is thereby caused which produces an audible sound.

The sounds in the telephone receiver last just as long as the sparks in the spark gap of the transmitting apparatus, and hence the signals transmitted are "heard" at the receiving station.

Details of Receiving Stations. A feature of all receiving stations is that the circuit does not only respond to oscillations of its own frequency, but to oscillations whose frequency is a harmonic of those transmitted; hence the detector will respond to oscillations of a frequency of one-third, one-fifth, and so on, of that of the circuit in which it is placed. Where the receiving circuit has the natural or fundamental frequency of the transmitting circuit, the signals are always the strongest; but the fact that harmonics will produce the desired effect renders the tuning very much easier. With damped oscillations, more especially, waves of slightly different wave-length to that for which the receiving circuit is tuned will produce audible signals in the receiver, but they are always weaker than those produced by the waves in proper tune. Modern apparatus usually provides a loosely coupled oscillation transformer, so that, when the tuning has been obtained, the coupling can be loosened until, although the signals are weakened, tuning is very sharp.

When listening for very long waves, such as those of the long-distance transmitting stations, a great deal of inductance has usually to be introduced into the aerial circuit. Very long aerials are employed for the long wave-lengths then employed; and as the average amateur station is usually provided with only a comparatively short aerial, many hundreds of turns of inductance may have to be employed. These long-inductance coils are easily made by winding enamelled wire, of No. 20 or 22 gauge, over an ebonite cylinder of about 3 in. diameter, and having preferably a sliding contact for tuning. The primary coil of the oscillation transformer or jigger is sometimes divided into a number of sections, so that, when tuning, the requisite number of turns of wire can be brought into play by means of a movable contact, C [20]. The looseness of coupling can then be arranged by sliding the secondary coil, S, wound on a cylinder which is movable in or out of the primary, P, nearer to or farther away from the primary. Very effective transformers of this type can now be obtained for amateur stations at very low prices, and are highly effective.

The Crystal Detector. The detector which is perhaps nowadays more used than any other is the *crystal detector*. A piece of crystalline carborundum is sometimes employed, placed between two brass spring clips, but a piece of crystalline silicon, with a gold-pointed wire pressing lightly against it, is the one most used by amateurs. A simple form of silicon detector is shown in **23**. The piece of silicon is fitted into a metal cup, S, and the gold-pointed wire, W, is made to press lightly against it by means of a tension screw, T. Means are usually provided for shifting the position of the cup, or of the wire, as it is always possible to find one particular part of the silicon which is more sensitive than any other. The effect of the wireless oscillations, when passing through the detector, is to cause heating, a thermal change which has a marked effect on the conductivity, the result being a variation in the telephone receiver, which is heard as a dull buzz.

There are various other forms of crystal detector which deserve mention, notably those in which two crystals are made to press lightly against each other. Copper pyrites, zincite, and a number of other crystals are employed, but the effect is the same in each case—namely, a heating of the contact and a resultant noise in the telephone due to the difference of potential caused.

Electrolytic Detector. A detector much in use in commercial stations is the *electrolytic detector*. This depends on the power of the electromagnetic oscillations to affect the passage of currents through electrolytes. De Forest, Fessenden, and Schloemilch are among those who have produced effective detectors of this type. A simple form is seen in **24**. A very fine platinum wire, about $\frac{1}{2500}$th inch in diameter, W, is fitted to the end of an adjustable screw A, which forms the anode (or positive pole), a small lead plate, C, forming the cathode or negative pole; the vessel is filled with dilute acid, and the fine wire, W, just dips into the liquid. The electrolytic cell is placed in series with a voltaic cell shunted by a small potentio-

meter, and a telephone is placed also in the circuit. The effect of the voltaic cell is to polarise the electrodes of the electrolytic cells, so that practically no current can flow through the telephone. The effect of the wireless oscillations is to depolarise the electrodes, with the result that current flows through the telephone and a noise is heard in it.

Fleming Valve Detector. The Fleming *valve detector* deserves particular notice, because it is rendered incandescent by means of a local battery, B, when the ionisation produced enables feeble currents to pass from the filament to an electrode, T, and the effect produced is that of *rectification*. Current can pass through the valve in one direction only, hence the small oscillatory currents from the aerial pass through the galvanometer in one direction, and can therefore be measured. A modification of the arrangement is employed when using a telephone receiver, and

is in use in many long-distance stations, and is of great value commercially.

One of the valves is shown in use in Fig. **22**. It is an exhausted bulb with a metal filament similar to that of an electric incandescent lamp, and the oscillatory currents from the jigger, J, are passed (with a condenser, K, shunted across the secondary) through the bulb or valve, V, into a very delicate galvanometer, G. The valve filament

this is in use in Marconi receiving stations on a very large scale.

When the received wireless oscillations are rectified in this way, it is possible to measure the infinitesimal amount of current obtained at a receiving station by means of a suitable galvanometer; the movements of the latter can be recorded photographically, and in this way automatic reception is brought about.

THE MASTER-MIND OF WIRELESS TELEGRAPHY

MARCONI, WHOSE WIRELESS SYSTEM SAFEGUARDS THE OCEAN TRAVELLER

Einthoven Galvanometer. The Einthoven galvanometer comprises a powerful electromagnet whose pole-pieces are tunnelled, and fitted with lenses. A beam of light is directed through the pole-pieces and focussed by the lenses upon a moving band of sensitive photographic film. A silvered quartz fibre, about $\frac{1}{1200}$th inch thick, is suspended between the poles of the magnet, and this acts as a minute shutter, which just shuts off the beam of light and prevents it from exposing the sensitive film. The received wireless currents, after rectification through a Fleming valve, are passed through the quartz fibre, and thereby produce a feeble magnetic field around it, whereby it is repelled, or forced to one side, by the repulsion of the field magnets. The beam of light is then able to reach the sensitive film and produce a developable impression upon it. Dots and dashes are represented as short and long deviations respectively of a narrow band on the negative when developed, and a permanent record of the wireless message is thus obtained. Automatic reception of this type has been carried out by Mr. Marconi across the Atlantic, and a somewhat similar type of receiver has been used by Poulsen, for which it is claimed that some 200 words per minute can be received.

The usual method of measuring the received current is by means of a *micro-ammeter*, an instrument which will record tenths, or even hundredths, of the one-millionth part of an ampere (1 unit of current). This is a hot-wire instrument, the heat generated by the passage of the oscillations producing sufficient distortion to cause deflection of a very delicately balanced needle working across a divided scale.

The Brown Relay. Another recent introduction of great commercial value is the Brown relay, by means of which the first or original minute current can be amplified to such an extent that a recording apparatus such as a Morse inker can be operated and the message recorded mechanically. The function of a relay has been described in TELEGRAPHY [see page 4467]. A relay used for wireless work performs the same functions, but essentially is much more delicate. By the use of a Brown relay for ordinary reception, it is possible so greatly to magnify the sounds in the telephone receiver that the receiver can be placed on a table or hung on a wall, and the signals will be audible anywhere in the room. If, instead of passing the amplified signals into a telephone receiver, they be passed into an ordinary automatic telegraph instrument, the dots and dashes of the Morse code will be recorded in ink on a moving paper ribbon. This method of automatic reception is much more useful than the photographic method above described, as the messages can be read the moment received, and no development of a photographic film is necessary. By using a series of relays, each amplified signal being transferred to the next relay, Galletti has recorded messages from Clifden at a station in France, over 1000 miles away, with precision.

The Orling Relay. Another relay which has been employed for long-distance reception for automatic working is that invented by Orling. In his instrument a projecting wire is fastened to the moving coil of a sensitive galvanometer, and this fine wire projects into a thin jet of acidulated water. When wireless oscillations pass through the moving coil (suspended between the poles of a powerful magnet), the coil twists slightly, and the fine wire deflects the water jet on to a contact, so that a local current is established, the jet itself forming part of the circuit.

Measurement of Waves. The measurement of the length of the waves used in wireless telegraphy is often of great importance. The *wave-meter* most ordinarily used is that made by the Marconi Company, and consists of a variable condenser placed in series with an inductance coil, this being usually made in two sections to give a wider range of use. The arrangement is shown in Fig. 21. J represents the inductance coil, which is wound inside the lid of the box containing the other apparatus; K is a variable condenser, D a carborundum crystal detector, and T the double headpiece telephones. When making a measurement, the telephones are placed to the ears, and the box is held a little distance away from the wireless circuit; the condenser is then adjusted until the signals are heard with the maximum loudness. By referring the figure on the scale of the condenser to a table already worked out, the wave-length is immediately found.

The distance over which messages can be transmitted depends very largely upon the wave-length employed, hence in long-distance transmissions a wave of seven or eight thousand metres is often used. As the natural wave emitted by the aerial is between four and five times the length of the aerial, it is desirable to have the aerial as nearly as possible in accordance with one-fifth of the wave used. This is the reason why in powerful stations aerials half a mile or more in length are used. As regards the reception of messages, a very long aerial is equally important, even though by reason of its length it may be necessary to use a condenser in series with it. Mr. Marconi recently, by means of an aerial suspended from a kite on board ship, received messages at a distance of over 6000 miles, and it is thought that this distance could have been increased had not a rise in wind necessitated pulling in the aerial.

Portable Sets. Military work requires a complete wireless installation of as portable a character as possible, which must, of course, be absolutely self-contained. The Marconi military set can be carried on five or six pack-horses, and consists of portable masts in sections which can be quickly put together, a small transmitter supplied with current from a dynamo driven by a small petrol engine, and a convenient receiving station mounted in a cabinet, in which the operator is protected from wind and rain. The masts are built up from their sections, and the aerial wire unrolled from reels, and suspended between the two masts. A roll of wire netting is spread over the ground to act as the earth, and the dynamo and generator are mounted one each side of one of the horse-saddles placed on the ground, with a direct-drive axle connecting them. A special feature of the system is that a key is provided with which the wave-length can be quickly changed, there being three available waves to work on. This makes it possible to avoid interference or interception of the messages to a great extent. The Fleming valve is used as the detector.

Portable receiving sets have also been made, sufficiently small in size to admit of the whole apparatus being fitted inside a knapsack; but unless an aerial fifty or more feet in length can be obtained at a reasonable height, and a good earth, there is little possibility of picking up anything but very strong signals, or signals being transmitted from a station not very far away.

Wireless in Airships and Aeroplanes. In the case of airships and aeroplanes the matter is different. As no earth connection is possible, one of two methods can be employed: either *balanced aerials*—that is, two equal aerial wires with a spark-gap between—like the original Hertz oscillator, or one aerial wire and a metal capacity. For the latter purpose such things have been tried as coating the gas envelope of an airship with aluminium leaf. It is quite customary, also, to have the aerial wires attached to insulators above an aeroplane, disposed like a fan or in some similar convenient fashion. In the early days of flight, when the author carried out the first experiments in this country on Salisbury Plain, two aerial wires were used on each side of the aeroplane, extending from the pilot's seat to the extreme edge of the planes and then back to the tail. This was a Hertz oscillator type of arrangement, and worked fairly well within a range of a mile or two.

It is very difficult to receive messages in aeroplanes, as the great noise of the engine and the vibration render hearing most uncertain; and as only very faint signals can be heard, the sounds in the telephone receiver are extremely low. Another difficulty in tuning is that the capacity of the aerial wires varies with their height from the ground, so that the conditions are in general highly unsatisfactory.

Wireless on Submarines. A considerable number of submarines are now fitted with wireless telegraph apparatus, but they are obliged to rise to the surface in order to hoist up the aerial above the water. The mast and antenna are thus what might be termed "collapsible." The range is, of course, limited, owing to the fact that a high mast is not possible, but a low or short aerial can always, to some extent, be compensated for by the use of a powerful transmitting apparatus. Continuous oscillations are of value here, as not only are they more efficient, carrying a greater distance for the same amount of power, compared with damped systems, but they have as long a range in daytime as at night. This is a peculiar feature of undamped waves which gives them a great value over damped waves.

Transmission without Aerials. There is another system of wireless transmission in which no aerial is employed at all, the waves travelling through earth or water; and although up to the present the distance covered has not exceeded six or seven miles, there is little doubt that it could now be greatly increased. Telephony is as easy by this method as telegraphy. A microphone is placed in series with a battery and small, low-resistance induction coil, and the ends of the latter are also connected with two wires stretching about fifty or sixty feet in opposite directions, and terminating in metal plates, either suspended in water or buried in the earth. The receiving station comprises a telephone receiver similarly connected with two wires terminating in metal plates. On speaking into the microphone, conduction waves are generated which travel outwards from the metal plates, and are picked up by the receiving plates and reconverted into speech in the telephone.

Sharman and Thorne Baker have also transmitted wireless signals through the earth over a considerable distance by merely having the wires ordinarily leading to the aerial and earth of an ordinary transmitting set attached instead to earth plates, similar earth plates at the receiving station leading to the receiving circuit. Quite sharp tuning is possible with this method of transmission, showing that wireless oscillations will travel through the earth in the same manner as they do through the ether under ordinary conditions.

The Wireless Compass. A great deal of work has been done recently in the determination of the direction in which wireless oscillations are travelling, the most practical apparatus being that invented by Bellini and Tosi, and since very much improved by Marconi. By means of the *wireless compass*—the name which has been applied to the apparatus—a ship can determine the locality from which signals are emanating, and by locating two—or, better, three—known stations, it can, in a fog, determine its own position with a considerable degree of accuracy. Many large liners are now fitted up with a wireless compass, and at certain dangerous points along the French coast special signals are sent out in foggy weather for their guidance.

For the purpose of location, a compound antenna is used; two nearly closed aerials (triangular shaped) are fitted up, usually disposed nearly at right angles, and one vertical single aerial, as shown in **25**. The vertical aerial and earth are connected with the ends of the primary or secondary of the oscillation transformer. The inductive coils of each triangular aerial are placed at right angles, and fixed as shown in the diagram, and the inductive coil of the plain aerial is placed inside them, and it can be rotated. To determine the direction of the signals, the movable coil is swivelled round until the sounds heard in the telephone are of maximum intensity. Two readings are sometimes taken of the positions of the movable coil when the signals in the telephone receiver just fall below audibility. There will, of course, be two such positions, one each side of the position of *maximum* intensity. These angles are measured by an indicator on a divided circle, and the direction of the signals then found by dividing in half the angle between the two measured positions. This gives accurately the position of *maximum* intensity.

Bellini and Tosi have constructed somewhat similar apparatus for directing transmission, but the real utility of their compound aerial and goniometer, or compass, lies in the ability of ships to determine their position by locating known transmitting stations. T. THORNE BAKER

Pronunciation. Nuances. Expression and Tone Colour. The Art of Correct Phrasing. Elocution and Declamation. How to Study a Song.

ARTICULATION AND PHRASING

Articulation. The great mistake so many singers make is that they give their undivided attention to the fulness and beauty of their voices, paying no heed to the diction; the words count for nothing, and are never thought of at all. It is as essential in singing as it is in speaking that the words should be clearly heard and the correct accent used—in other words, that the articulation and pronunciation should be irreproachable.

Articulation must not be confused with pronunciation, for there is a great difference between them. Words are made up of syllables. Each syllable contains one vowel and one or more consonants. When each vowel and consonant is clearly and correctly uttered, the *articulation* is perfect. The reason why English people articulate so indistinctly is that they hurry over their words. More *deliberate* articulation is needed. The famous Mrs. Siddons used to say to her pupils, "Take time!"

It will be found that the consonants offer greater difficulties than the vowels, so the first exercises will be on the consonantal powers.

It must be borne in mind that the consonants are not all formed alike. Roughly speaking, they are divisible into five groups:

1. LABIAL, formed by the approximation, or the complete contact, of the lower and upper lips—pen, bat, man, wench.

2. LABIO-DENTAL, formed by the contact of the lower lip with the upper teeth—fine, verse.

3. LINGUA-PALATAL, formed by the tip of the tongue coming into contact with the hard palate immediately behind the two upper front teeth—ten, did, line, night, sell.

4. LINGUA-GUTTURAL, formed by the back of the tongue coming in contact with the hard palate—kind, gag.

5. ORAL, formed by a full flow of breath through the mouth—hall, yolk.

The student must first persevere with the actual powers themselves, and not add the vowels until the consonants have been *thoroughly* mastered, thus:

B	as in bad	N	as in name
C	,, cakes	P	,, pill
D	,, dane	Q	,, quilt
F	,, fight	R	(trilled) as in rat
G	,, gauge	R	(smooth) as in war
H	,, hat	S	as in sill
J	,, jet	T	,, tone
K	,, kick	V	,, vain
L	,, lark	W	,, well
M	,, mart	X=KS	as in mix
		Wh	as in white

Each of the powers given in the above list, beginning with B, must be practised at first *very slowly*, thus: B′B′B′B, breathing after each B. Then in four groups of two, breathing after each group; four groups of four, breathing after each group; four groups of eight, breathing after each group; then in groups of twelve, sixteen, twenty, and so on. The greater the speed, the lighter and crisper must be the articulation. The sound actually uttered is not Bee, but B as heard in the word "bad" minus the "ad" sound.

After having practised the above exercise the student should make out lists of words for each consonant, thus: Ball, bat, bell, bed, bile, bid, boy, boil, book, booth, etc. Then sentences something like these: "Black Benny Bumpkins bought beautiful blackberries, but Bertha Brown bartered Benny's best boat for bananas."

This must be practised carefully in two breaths—that is, breathing after blackberries; then the whole exercise in one breath: afterwards tried twice, three times, and four times, if possible, in one breath, throughout paying the greatest attention to the "B" power.

Having learnt something of the consonantal powers, the student must turn his attention to the vowel sounds. Whilst only five signs are used—A, E, I, O, U—they represent a great many more vowel sounds.

Five sounds for A, as in ape, ah, all, at, air.
Three sounds for E ,, eel, ell, earth.
Two sounds for I ,, ice, ill.
Two sounds for O ,, old, odd.
Three sounds for U ,, up, (n)ude, (f)ull.

O is also represented in the diphthongs, as in boy and owl.

Although the vowel sound emanates from the larynx, the real formation is decided by the different shapes assumed by the inside of the mouth and the pharynx.

The student must make for himself lists of words on each of the vowel sounds given above, thus: A as heard in ape, ale, fate, pate, grate, and practise them many times, listening carefully to each sound produced, and continue until he has thoroughly mastered them.

When he has overcome the difficulties in the preceding exercises, he should take sentences such as this from Ruskin:

"Blue, baseless and beautiful
Did the boundless mountains bear
Their folded shadows into the golden air."

Recite them very slowly, and pronounce every vowel sound fully, correctly, and distinctly.

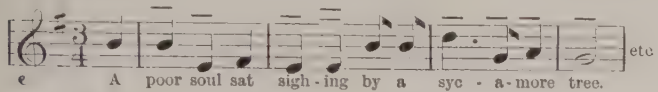
Pronunciation. Good pronunciation is really "proprietry of delivery." It is not so easily taught as is articulation; so much depends upon the student's own intelligence and his capabilities for hearing and discriminating between words correctly and incorrectly pronounced.

To a very large extent, correct pronunciation depends upon their proper use; but besides practising the vowel sounds, it is necessary to hear, listen to, and copy the best orators and actors of the day if good pronunciation is to be obtained.

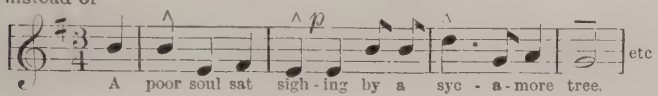
Apart from the different brogues of Scotland, Ireland, and Wales, the English counties have peculiarities of pronunciation that ought to be eradicated, such as: "t' cat" for "the cat" (North Lancashire); "th' cat" for "the cat" (South Lancashire); "Charing-Crawss" for "Charing Cross" (Cockney); "Eow" for "Oh" (Cockney); and many more that can only be corrected by listening to a cultured speaker. It is not intended that the student should regard pure dialects as

vulgarisms; it is the mixture of "polite speech" and dialect that is so ugly. In a number of real dialect words many of the roots of the English language are traceable, for they are chiefly of Celtic, Teutonic, Scandinavian, and Anglo-Saxon origin.

It is generally imagined that the English language is bad for singing. The sooner this absurd idea is abolished the better. The real reason why a voice does not sound so full and resonant when singing English words as it does when singing Italian is that the singer neglects to give the full value to the vowel sounds, and does not articulate his consonants sufficiently, besides invariably "clipping" them. Another common mistake made by singers is that they are not careful to give each syllable its proper accent, for example:



instead of



As first marked, the words would read as follows, and make no sense:

"A *poor soul* sat *sighing* by a *syc-a-more tree.*" We do not pronounce the letters s y c a m o r e as *syc-a-more,* but syc-amore, so why sing the word with three accents?

The consonants must be more marked in singing than in speaking, because the vowels are more prolonged and have often to be made broader.

Great care must be taken that the end of a word is not carried on to the beginning of the next—that is to say, it must be finished on the note intended by the composer; the consonants must be articulated distinctly, especially the d's and t's; and the r's trilled where necessary, but under no consideration must false accents be introduced in the endeavour to begin or finish the words.

Nuances. "Messa di voce" has been defined as "the swelling and diminishing of the sound of the voice upon a holding note." To obtain this a note must be attacked *very* quietly, gradually increasing in force until the loudest tone is obtained, then must be diminished carefully and gradually until the original power of tone is reached.

These swelled sounds are shown thus , and this sign usually applies to *one* note only, although it may happen that a whole phrase is to be included. But in either case it must be executed in *one* breath. At first the student must practise half the exercise—that is, begin very softly, making a gradual crescendo from the softest to the loudest tone. This should be practised twenty times, then the process should be reversed, begun very loudly, gradually diminished to a *pp.* This, too, should be practised many times. Finally the whole exercise should be practised.

Rules for Singing "Messa di Voce." The following rules must be observed:

(1) Breath must be inhaled slowly, calmly, quietly, and deeply before each exercise.

(2) The vowel sound must not alter as the note becomes louder or softer.

(3) Once the note is attacked the mouth must remain unaltered.

(4) The quality of the note must be unchanged throughout.

(5) The note must *not* be held until the last particle of breath has been exhaled; a little must remain in the lungs after the completion of the note or phrase.

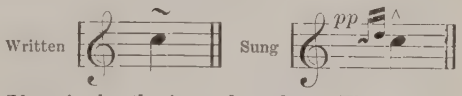
The "messa di voce" may be practised on all the notes suitable for the respective voices, given in Ex. 1 [pages 5765–6], the vowels A (ah) and E (ee) being used.

The object of "messa di voce" is to give colour to the singing. It must not be attempted until the student has acquired a correct management of the breath.

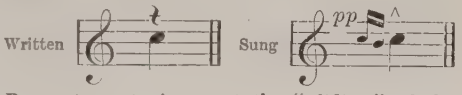
The principal ornaments used in singing are the appoggiatura, acciaccatura, mordente, grupetto or turn, shake or trillo, portamento, legato, staccato, and picchettato.

[The ornaments appoggiatura, acciaccatura, grupetto or turn, shake or trillo, are explained fully in the chapter on "The Whole Language of Music," on page 236; their meaning should be thoroughly understood by the singer.

The mordente consists of the written note, the note above—either tone or somitone—and the written note.



There is also the *inverted mordente.* This consists of the written note, the note below and the written note.



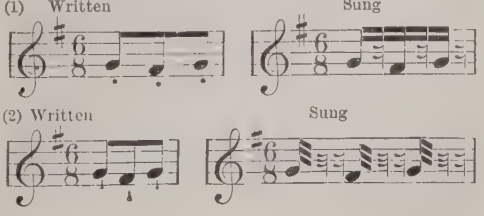
By portamento is meant the "sliding" of the voice from one note to another of different pitch. When used with discretion it is very effective, but a common mistake made by many singers is that they use it continually without discretion. As to how it must be sung—slowly, or quickly, loudly or softly—the student must be guided entirely by the context. The following sign ⌒ or ⌒ is used.

A note must never be "slurred" to and then from consecutively.

The sign called a slur, used for the legato, is written ⌒. The notes over which the slur is placed must be sung very smoothly, but there must be no "sliding" of the voice from one note to the next, and the notes intervening between the written notes must *not* be heard as in portamento.

Great care and perseverance must be exercised before the legato can be acquired; but once the student has mastered its difficulties, he is amply repaid, for, as Signor Randegger says, "Efficiency in *legato singing* is the most prominent and valuable attribute of a good singer."

Speaking generally, it may be said there are three kinds of staccato.



3) Written Sung

No. 1 is usually called staccato, and No. 2 picchettato. The notes marked picchettato are half as short again as those marked staccato.

The strictest attention must be given to the rests between the notes; neither the voice nor the breath must be heard.

Breath must not be inhaled between the notes, but that which was inhaled at the beginning must be regulated so that it is sufficient for the whole phrase. Each note must be firmly and sharply attacked.

In singing No. 3 the notes should be firmly attacked, but not so marked or detached as in Nos. 1 and 2. The student is advised to write exercises for himself on the different ornaments and embellishments, and then practise them carefully and diligently in the keys best suited to his voice.

Word Picturing. Upon "word picturing," facial expression, tone colour, emphasis, expression, and phrasing, all to a large extent depend. Each of the above will be treated separately; but it is essential that the student should first really understand what is meant by "word picturing."

Before a student can do justice to a song he wants to sing he must take the words apart from the music, read them through carefully and thoughtfully, then re-read them. They may be merely descriptive, or they may be of an emotional nature combined with description. No matter of what nature they may be, the student must draw upon his imagination and make *mental pictures* of the scenes and emotions to be portrayed, as an artist has to do before he can place on canvas illustrations of a poem.

To a painter this word picturing is, perhaps, more natural than to a singer; the former is trained from the first to make a mental picture of all he reads. Here is this difference between the painter and the singer; as the latter will probably have to describe the whole of the poem, he must, perforce, *mentally see* the *whole* of it, whereas the painter is limited to a few lines, for he cannot paint a picture illustrating the whole of the poem.

The student will find it very helpful—until he is able to draw upon his imagination more, and mentally make pictures for himself—to recall past experiences in his life, and work on them. For example, if he is singing of a lovely garden, or a quiet graveyard, he must think of some garden he knows that once appealed to him, or a quiet, peaceful graveyard he has seen and noticed; if he is singing of a person, he may think of someone he knows who seems to fit the situation; if his song refers to the passions or emotions, he must think of the time when he hated, was afraid of, loved, or was angry with some person, and he must try and recall some of the feelings he may then have experienced, and work them into the song. The whole of what is represented in the song must be *mentally seen* if he wishes to make the rendering of it clear to his audience.

Facial Expression. For examples of real facial expression one should look at the face of a child. How quickly its little face brightens, and with what smiling eyes it looks at one when anything pleases it! On the other hand, how suddenly its wee face clouds if it is disappointed, and how it pouts when it is cross!

As the child grows up it gradually loses this natural unconsciousness of self, and perhaps unconsciously strives to hide these varying expressions which are the outcome of the thoughts and emotions. English people are much too reserved; they will not speak with their eyes and the expression of their faces—they rely entirely upon the mere words.

For those whose calling does not bring them before the public, this may be passable; but to anyone who wishes to be a singer, reciter, or public speaker, facial expression is as essential as a properly produced voice. The expression of the face must change with the mood.

No hard and fast rule can be laid down for facial expression, as all the expressions natural to one's face are the outcome of one's inmost thoughts.

The student must make a list of the different emotions—love, hatred, rage, and so on, and, standing before a mirror, practise the different facial expressions which represent each. He will see for himself how necessary it is to get a thorough reading of his song, and practise his "word picturing." When these have been mastered, facial expression will come quite naturally to him.

Tone Colour. When the student has thoroughly grasped the meaning of the words of his song, and made himself quite familiar with all the moods contained therein, he will unconsciously have acquired the correct "tone colour" for each musical sentence. He would not use the same "tone colour" for "O rest in the Lord; wait patiently for Him," that he would for "Awake, Saturnia, from thy lethargy!" For the former he would use a warm, comforting, persuasive tone, whilst for the latter he would use a sharp, commanding, peremptory one. Ere the student can hope to attain proper tone colour, he must thoroughly understand the words he is about to sing.

Emphasis. Some singers may argue that "emphasis" does not apply to singing; that it chiefly concerns readers, reciters, and speakers. This is not so; it is as necessary to the singer as to the speaker. Every word in a phrase must be given its due importance, but one of them must be more strongly emphasised than the others, to point to the real meaning of the sentence.

The whole sense of a passage may be altered if emphasis is not put on the right word. The following examples show the correct and incorrect emphasis: "Greater love hath *no* man than THIS, that a man lay down his *life* for his friends." Properly emphasised, the word "*this*" takes the especial prominence, whilst the words "no" and "life" are the next in importance.

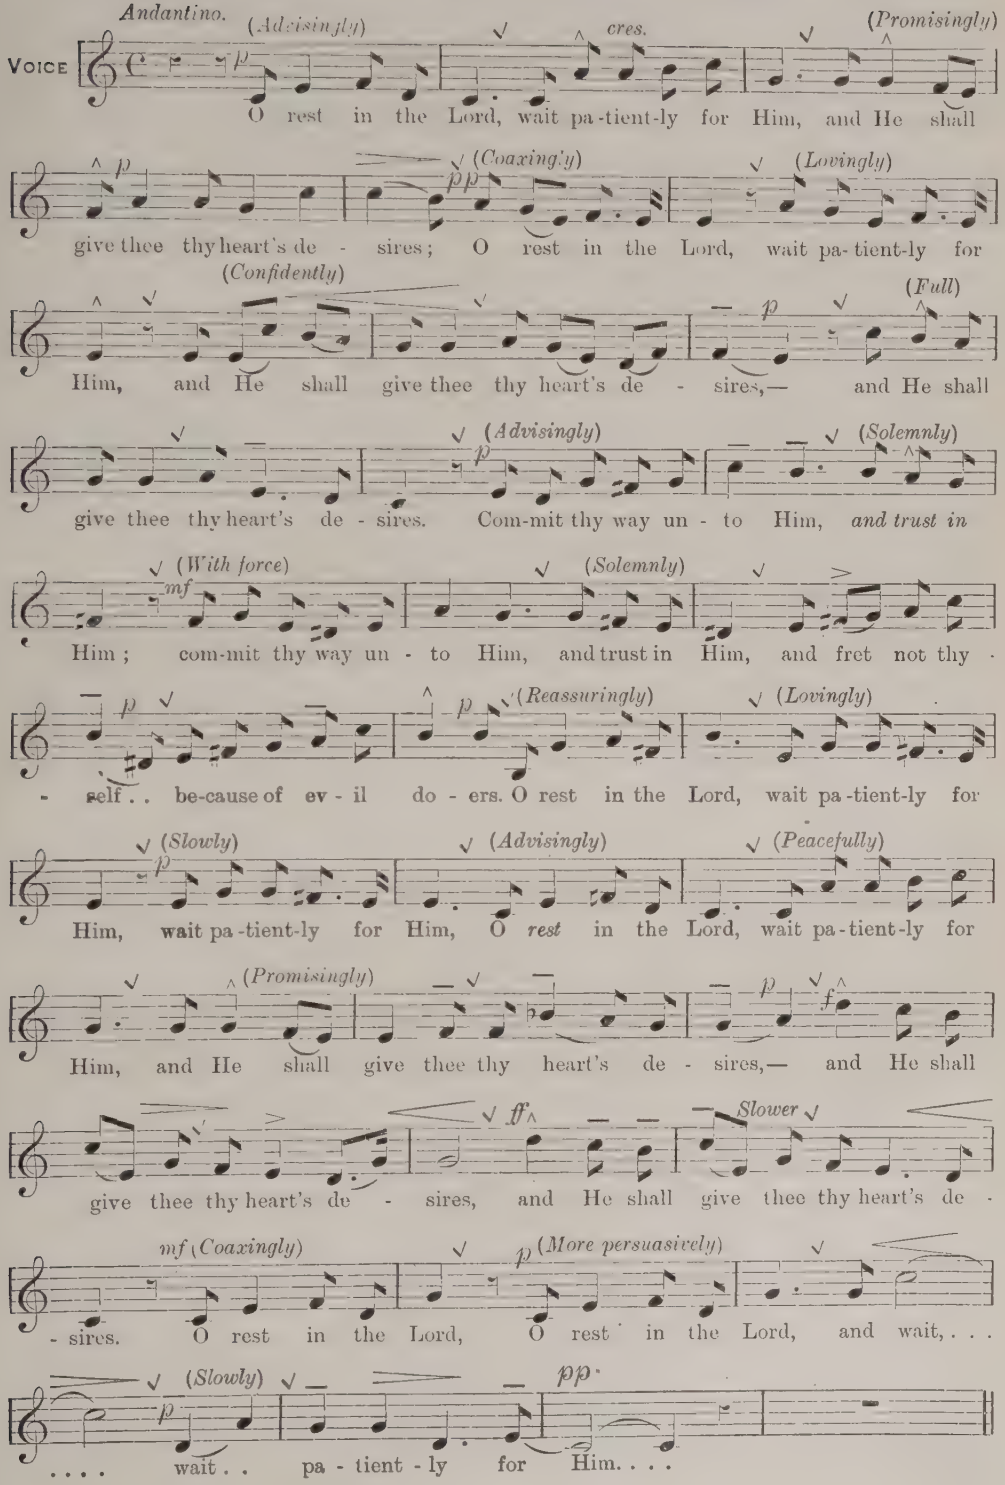
Wrongly emphasised, it would read as follows: "Greater love hath no *man* [as opposed to "woman"] than this, that a man *lay down* [not "take up"] his life for his friends."

The student will see for himself how this sentence can be turned about, and wrongly emphasised and made absolute nonsense of; further, he will see how essential it is that singers, as well as speakers, should emphasise correctly.

Expression. Rousseau says: "Expression is the power whereby the musician conveys to his audience all the ideas and sentiments of the music which he interprets, at the same time making it evident that he feels them himself."

Some natures are less responsive than others, but with patience, perseverance, and a tactful handling, feeling can be brought out of the coldest natures. The terms expression and feeling, as applied to singing, are synonymous, therefore every person is capable of singing with "expression."

Aria—"O REST IN THE LORD."



Andantino.

Expression cannot actually be taught, but it can be cultivated, and to such an extent that the performer really feels what he is singing; and, what is still more important, makes his audience feel it, too. There are, of course, some people whose singing is naturally sympathetic and full of feeling, but this need not discourage the less fortunate ones, for everybody who wishes can sing with expression. The easiest and quickest way to cultivate this great gift is to read good literature, especially poetry, thoughtfully and with understanding.

Phrasing. Phrasing may mean merely a correct punctuation of a musical phrase, as: "Woe! Woe unto them who forsake Him!" (Elijah); but when one speaks of a song and piece being correctly "phrased" one generally understands that the best possible effect has been given to each of the musical sentences contained therein. This can only be accomplished after the performer has thoroughly grasped the *meaning* intended by the composer, and fully realised his ideas; he will then portray them in such a way that the audience cannot fail to grasp them too.

Besides this, he must have mastered the art of breathing, have had his voice properly produced, have studied articulation and pronunciation, be able to keep time and sing "in tune," know where to take breath, be able to use the correct "tone colour," be able to sing legato and staccato, and be thoroughly proficient in the singing of all the different ornaments and embellishments. Lamperti, in his famous "Art of Singing," says that "the whole beauty of the art of singing lies in phrasing."

We give on the next page "O rest in the Lord" fully marked, and the student is advised to study it well. For his guidance we also give a list of the signs used:

√ Where breath is to be inhaled.
| Voice to cease, but no re-inhalation.
/ Inflection of the voice to rise.
\ Inflection of the voice to fall.
∧ Strong accent.
– Medium accent.

Elocution and Declamation. It is essential that the student of singing should study elocution and declamation. Unless he does so he will find it almost impossible to deliver his song to its greatest advantage—to give it the poetical sense and the true expression intended by the composer. Many teachers of singing are quite opposed to their pupils' studying elocution and declamation. They imagine it injures the singing voice; but this is an absurd idea. If the student uses his speaking voice properly and in moderation, no possible harm will result. Cavaliere Alberto Randegger, one of the most famous professors of singing, writes: "Elocution and declamation should form an integrant part of the singer's education."

A dictionary would probably describe a song as a short poem, a ballad, a lay or a strain, but none of these synonyms fully define the word. A song is the combination of words with the singing voice. One is indispensable to the other, and they are equally important. When it is remembered that words set to music make the conception absolute, it will be seen how important a part they play.

The First Song. The first song chosen should be very simple, slow, sustained, well within the compass of the voice, the intervals not too difficult, and the accompaniment quite easy, so that if the student is obliged to play his own accompaniment he can do so without paying much attention to it, and so give all his thoughts to his voice and the words. A short song such as "The Sweetest Flower that Blows," by Hawley, or "The Night has a Thousand Eyes," by Frank Lambert, is recommended.

The student must read through the words carefully, and when he has grasped their meaning read them aloud as though they were the outcome of his own thoughts, breathing where the sense dictates.

Before beginning to sing them he is advised to learn them by heart. He should then give his attention to the song, first noticing the key, time, and marks of expression before uttering a sound. Next he should slowly sing through the melody to "La," keeping perfect time; and finally he should take the words and music together.

Recitative may be defined as a musical declamation or a speaking in music. There are two kinds—accompanied and unaccompanied. In singing the former the student must keep strict time. Example: "Awake, Saturnia" (No. 28, Handel's "Semele").

When a recitative is unaccompanied the singer makes the time according to the words of the story and his own reading of the piece. Example: "O, worse than death" (No. 17, Handel's "Theodora").

For both accompanied and unaccompanied recitative singing the meaning of the words must be very carefully studied, so that the sentences may be correctly phrased and the proper emphasis given. At all times must the words be clearly pronounced.

When studying the unaccompanied style, the student is advised to select several recitatives, and take the words quite apart from the music and read them aloud as he would a verse of poetry or a piece of prose. Having satisfied himself that he has obtained the correct meaning and effect, he may then sing them, but the phrases must be the same as when declaimed.

Three Styles of Singing. Generally speaking, there are three styles of singing—plain, florid, and declamatory. For the first the essential and distinct attributes are perfect intonation, correct breath management, and faultless diction. This is the noblest of all styles, and to it belong church music and oratorios. Example: "If with all your hearts" (Mendelssohn's "Elijah").

The florid style is not so frequently heard nowadays as it was some years ago. It is full of ornaments—grace-notes, shakes, turns—arpeggios, scale passages, etc., and the "tempo" is usually quick. For the singing of this the voice must be light and full, and the breath well under control. Example Bishop's "Lo! here the Gentle Lark."

It is to the delivery of the words that the attention is chiefly given in the singing of the declamatory style; vocalisation is practically unnecessary. Example: Schubert's "Aufenthalt."

The Young Singer's Début. It is quite possible that the average student will feel very nervous and awkward when he makes his début as either a professional or amateur singer. This is natural enough, and only time and experience will enable him to obtain perfect self-possession; but he should bear in mind that however nervous or anxious he may feel he must do his utmost to hide it, for nothing is more trying to an audience than a nervous performer. He should come well forward on to the stage, and his face should assume a pleasing expression. The student may at all times be *anxious* when he sings publicly, but it is certain he will not be nervous if he understands and has thoroughly mastered the piece he is about to sing.

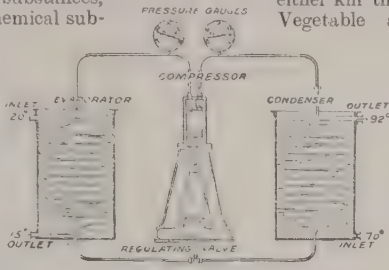
FOOD PRESERVATION

It is a common matter of everyday experience that most foods, especially those of animal origin, are subject to decomposition if kept beyond a certain period. Before we can properly appreciate the value of the different methods of preserving foods it is absolutely necessary for us to form a clear conception of the causes which bring about decomposition and putrefaction.

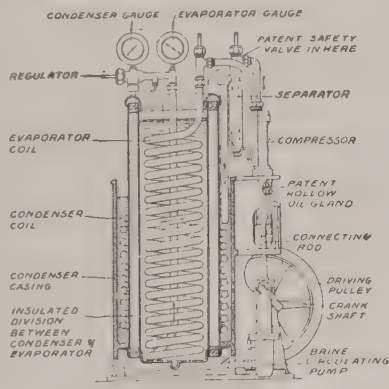
Why Food will not Keep. Foods are mixtures of complex organic substances, and when they go bad these chemical substances undergo chemical changes with the formation of other substances characterised by their unpleasant taste and smell, or by poisonous properties. These chemical changes are brought about by minute organisms (micro-organisms), which are invisible to the naked eye. [See Bacteriology]. All decomposing substances, when examined under the microscope, are seen to be swarming with innumerable organisms of varying shape and form. They are so universal that it is no easy matter to prepare liquids free from them and keep them in this state. Water taken from any pond, well or stream, even fresh rain water, teems with life when examined in this way. Like all living things, these micro-organisms bring about the chemical transformation of matter by "feeding on," or absorbing, substances in one form and excreting them in another, or else producing ferments which bring about these changes. It often happens that substances produced by one organism become the food of another, so that a whole series of chemical changes are brought about. This happens when any animal foodstuff undergoes putrefaction. The danger of consuming such food lies in the small quantities of poisonous products (ptomaines) they may contain. In the early stages of decomposition food is often covered with furry growths, commonly known as moulds. These are well characterised forms of plant life. They are of considerable importance as they prepare the way for the development of other more minute organisms and bacteria. If only we could exclude these organisms, it might be possible to preserve even the most perishable of foods indefinitely.



1. REFRIGERATING MACHINE
[Diagrammatic view]

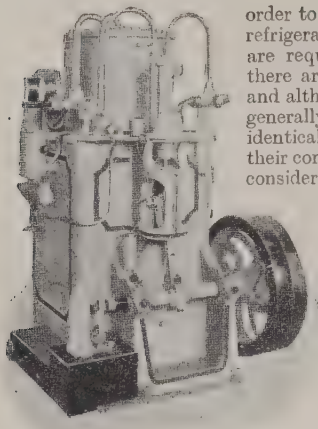
How Bacteria are Kept in Check. Having shown that food will not keep because of the action of micro-organisms, it will now be our business to inquire into the conditions under which they live, in order that we may learn how to control them. The spores, or seeds, are extremely minute, are always found floating in the air, and are continually settling like dust on every object. Wherever they find favourable conditions and suitable surroundings they quickly obtain a foothold, and breed and multiply. These conditions may be classed under four heads: (1) Supply of suitable food; (2) presence of moisture; (3) suitable conditions of temperature; (4) absence of substances which either kill them or prevent them developing. Vegetable and animal matter, including foods for human consumption, all provide suitable food for micro-organisms, but it is essential for their development that moisture should be present, hence the primitive method of preserving food by drying, and therefore excluding moisture. Thoroughly dried foodstuffs will keep an immense time. The organisms may be there, but have not a chance of developing.

Cold Storage. Food may be preserved by taking advantage of the fact that bacteria will only develop within a certain range of temperature. Thus below about 50° F. their activity is almost entirely arrested; above 170° F. bacteria are destroyed. We shall confine our attention, to start with, to those methods of preservation dependent upon low temperatures, and generally known as refrigeration, or cold storage. The food, whether meat, fish, vegetables, or fruit, is kept at a low temperature until required for consumption. This is perhaps the best method of preserving food as it adds nothing to and takes nothing from the article, so that no change is brought about, and the food remains as nutritious and digestible as before treatment. The advantages of cold storage will become apparent when we see some of the disadvantages attached to the other methods of preserving food. By the aid of cold storage hundreds of thousands of tons of different foodstuffs are imported annually into this country without the use of any chemical preservative. When the ship arrives here the foodstuffs are taken out of the refrigerating chambers, and placed in cold stores until required. We shall now describe the machinery and plant used in this connection.



2. SECTION OF A LAND TYPE OF REFRIGERATING MACHINE

Refrigerating Machines. The rooms in which foodstuffs are stored are generally kept cool by a system of overhead pipes through which cooled brine circulates. Brine is chosen, as it can be reduced to a low temperature without freezing. In

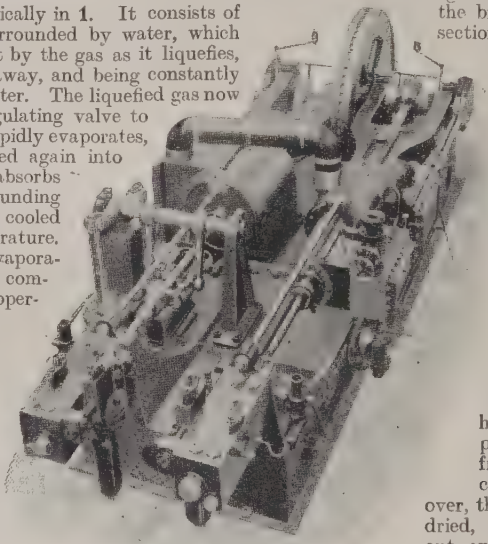


3. LAND TYPE OF CARBONIC ANHYDRIDE REFRIGERATING MACHINE

order to cool this brine refrigerating machines are required, of which there are several types, and although those now generally employed are identical in principle, their construction varies considerably. The principle involved is as follows:

By means of a compressor, certain easily liquefied gases, such as carbon dioxide, ammonia, or sulphur dioxide, are condensed to a liquid in a condenser. The condenser is shown diagrammatically in **1**. It consists of a long coil of tubing surrounded by water, which absorbs the heat given out by the gas as it liquefies, the warm water passing away, and being constantly replaced by fresh, cold water. The liquefied gas now passes on through a regulating valve to the evaporator, where it rapidly evaporates, the liquid being converted again into vapour; in doing this it absorbs heat from the brine surrounding it, so that the latter is cooled down to a low temperature. The gas, as it leaves the evaporator, passes again to the compressor, and the cycle of operations is repeated. Provided there are no leaks, no fresh gas is required, since it is used over and over again.

The Chief Gases Employed. Opinions differ as to the most suitable gas, but we may mention three which can be used—namely, carbon dioxide (carbonic anhydride), ammonia, and sulphur dioxide gases. Carbon dioxide gas is cheap, costing only a few pence per pound. On the other hand, ammonia has the advantage that it is liquefied at a lower pressure. While carbon dioxide requires, in temperate climates, a pressure of 850 lb. per square inch for liquefaction, ammonia may be worked at a moderate pressure of about 120 lb. to the square inch. On the other hand, all compressor parts of the carbonic acid plant are much smaller. Ammonia is an alkaline gas, and in the presence of air will dissolve copper and other metals, so that in ammonia machines all copper, or copper alloy, must be avoided in any parts which come in contact with the ammonia. This is a great drawback to the use of ammonia machines where only sea-water is available for cooling, as the iron pipes, which alone can be used, are quickly corroded by sea-water. If it should escape, the smell is objectionable, though scarcely unpleasant, and in case of a serious escape it would prove dangerous. Sulphur dioxide is, perhaps, the least suitable of all three. It is not difficult to liquefy, but is more corrosive, especially as it is liable to be converted, by oxidation, to sulphuric acid in the presence of air and moisture.

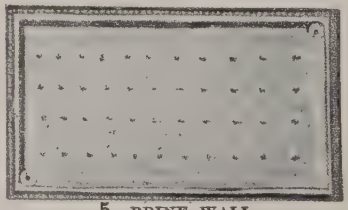


4. MARINE TYPE OF CARBONIC ANHYDRIDE REFRIGERATING MACHINE

In connection with cold storage we shall describe machines worked with carbon dioxide gas, but will treat of a machine using ammonia gas when dealing with the cooling of pasteurised milk.

Cold Storage Chambers. Figure **2** shows, in section, the construction of a carbonic anhydride refrigerating machine. Fig. **3** is an illustration of this machine, which, of course, can be used not only for cooling brine for cold storage chambers, but also for making ice, cooling water, or all purposes combined. It will be seen, as illustrated in **1**, that the compressor forces the gas into the coils of the condenser, which are contained in an annular vessel surrounding the evaporator, a space fitted with an insulating material being left between the two. The crank shaft not only works the compressor, but also a small pump, which drives the cooled brine from the inner vessel, and causes it to circulate through the pipes in the cold storage rooms. These brine tubes are made in long lengths, sometimes 200 ft., electrically welded, and are known as grids [**6**]. In large installations, the brine grids are divided into sections, each section having a separate return pipe back to the machine, where valves are placed for regulating the quantity of cold brine circulating in each section as required by the temperature in the room; a system of this kind is necessary in order to obtain a regular temperature in the cold stores. The grids are generally fixed at the top of each room under the ceiling, and, the air in contact with the pipes becoming colder, and consequently heavier, descends, and is replaced by "less cold" air from beneath, producing a constant circulation. Moreover, the air is not only cooled but dried, as the moisture separates out, and condenses on the grids. The quantity of cooled brine contained in the system of grids is very considerable, and this acts as a reservoir of "cold," so that in many cases it is unnecessary to run the refrigerating machine continually, but only for a few hours daily.

In some cases, especially when storing butter above 32° F, and all kinds of fruit, a circulation of cold air is preferable for cooling the chambers, in which case a number of grids are placed together in convenient proximity to the refrigerating machine, and air is drawn through them by means of a powerful fan, and conducted by means of air ducts to the cold rooms. In some meat-freezing



5. BRINE WALL

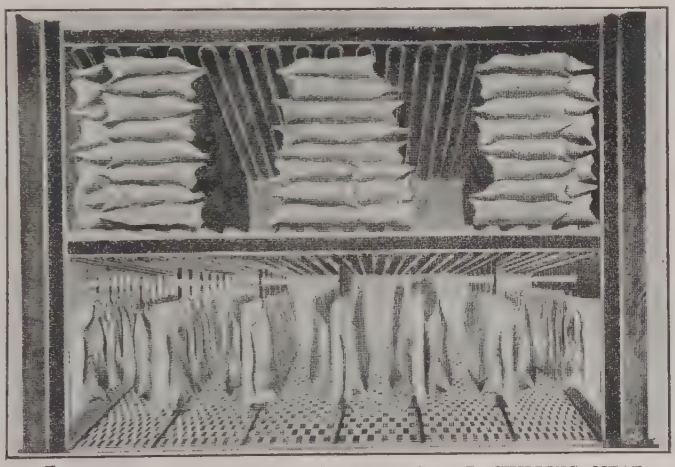
works it is the practice to install brine walls, which consist of large, flat, very shallow boxes [5] made of steel plates placed parallel to each other at convenient distances, through which the cool brine is circulated. In the passages between these walls the meat to be frozen or chilled is hung, as illustrated in **7**. The brine grids are seen beneath the ceiling, and the brine walls between the rows of carcases. In the rooms overhead, fitted with brine grids, the frozen meat is stored. The brine system is also largely used for bacon curing. The sides of bacon are hung up in rooms chilled by brine pipes, and generally with cold air circulation to 40° F., which temperature minimises the tendency to putrefaction, while, on the other hand, it is the lowest temperature at which the meat will "take" the salt perfectly. Fruit can also be very advantageously stored in cool chambers, either for carriage over long distances, or to keep back a glut until a time at which it will fetch a considerably enhanced price.

6. BRINE GRID

Refrigeration in Factories. Another instance in which refrigeration may usefully be applied is in cooling chocolate, in order to hasten and facilitate the removal of the tablets from he moulds. This is a very difficult operation in summer under ordinary conditions, when the chocolate tends to adhere to the moulds, making it necessary sometimes to remelt and cast again.

Brewing is a delicate operation depending on the growth of yeast, which is much influenced by temperature. A refrigerating machine is therefore of great importance in a brewery, where it is used to cool a large quantity of water for refrigerating the "wort" and maintaining the correct temperature in the "tuns." Moreover, the finished beer should be bottled at a low temperature.

Multifarious as are the uses of cold storage on land, it is, if possible, of greater importance in the shipping of frozen meat from our Colonies. For such purposes large marine-type machines are employed, as shown in **4**, while for preserving passengers' provisions the machines illustrated in **8** are used. The principle in all these machines is similar to that already described. Figure **9** shows a typical installation for the carriage of frozen meat on board a White Star vessel, on the system of Messrs. J. & E. Hall, Ltd., to whom we are indebted for illustrations **1-9**.



7. BRINE WALL SYSTEM OF FREEZING AND CHILLING MEAT

Preservation of Milk. We now come to another important application of the principle of refrigeration—the treatment of milk. There are very few substances which are commonly used for human consumption so susceptible to the action of bacteria as milk and cream. The rapid decay of these substances, which is commonly and popularly called "souring," is caused by the presence of micro-organisms. It is well known that "souring" goes on much more quickly in warm weather than in cooler weather, and it is likewise known that milk can be kept from turning for certain periods by being put "on ice," or in an ice safe. It is, of course, simply a case of arrested growth of bacteria; the organisms themselves are not destroyed by this action.

Pasteurisation. The process of pasteurisation, which may appear to be rather mysterious to persons not familiar with it, is a comparatively simple operation. In reality, it is a process of heating the milk or cream to a temperature that will destroy the disease germs and chilling it at once in order to prevent the spores from germinating and setting up another generation of micro-organisms. The rapidity with which these spores develop is astonishing, and the practical way of dealing with milk is to deal with it as quickly as possible after being taken from the cow, chill it down at once, and keep it at a low temperature. [See AGRICULTURE, pages 2943 and 3067.

Public opinion, combined with legal necessity, fixes the standard which the practical dairyman must attain, and the demands upon the dairyman are constantly becoming more and more severe.

There are, of course, difficulties connected with the process of pasteurisation, and they lie in the accomplishment of the desired result without injuring the milk or changing its consistency, for which machinery properly adapted to the purpose is essential. Properly pasteurised milk has been recommended by the best physicians.

The ordinary pasteuriser which has hitherto been used is shown in **10**, and consists more or less broadly of a vertical cylindrical vessel surrounded by a steam jacket. Within the vessel is placed a vertical spindle having a paddle or stirrer fixed to it, driven by suitable gearing from any source of power. The steam is turned on to the jacket, the milk allowed to flow into the machine, and the paddle set in motion. It is assumed that the whole of the milk becomes pasteurised in being rapidly stirred round and thrown against the steam-jacketed sides of the cylinder. Unfortunately, this assumption is not quite correct, as a portion of the milk does not come into contact with the heated sides of the cylinder, and passes away through the outlet without having

been raised to the requisite temperature to destroy the micro-organisms.

On the other hand, much of the milk is heated to too high a point, and coagulation of the albumen results, impairing the digestibility of the milk. Although the outflow from the pasteuriser may give the correct temperature of about 165°, it will be evident that some of the milk has been heated too much, and some insufficiently heated.

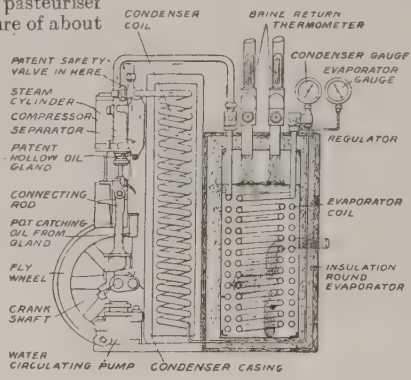
It should be mentioned that another drawback connected with the vertical pasteuriser with revolving spindle is that the step or joint upon or through which the spindle is situated forms a pocket where a little liquid is likely to remain, providing an ideal habitat for bacteria.

New form of Pasteuriser. In the newer type of machine the milk does not pass through a cylinder, and is not knocked about by a revolving paddle, but flows over a series of revolving drums which are semi-submerged in milk troughs.

In the case of the machine illustrated [11] the milk is allowed to flow slowly into the top trough, in which revolves a tinned copper corrugated drum, through which hot water passes at the requisite temperature. As the drum revolves, a film of milk adheres to it, and is carried over with it and heated to the right point. The outflow from the top trough is taken to a point where the heated milk naturally flows off, and none can go over excepting that which has been brought over by the revolving drum and properly heated. No milk can be overheated, and every particle of milk comes into contact with the drum without being churned or otherwise knocked about. In the second trough is a second revolving drum, through which ordinary water is constantly flowing. This water reduces the temperature of the milk to about 60°, and the milk then flows out into the third trough. A circulation of cold brine at about 35° passes through the third revolving drum, and reduces the milk to about 40°, at which point the milk flows out into a suitable receptacle.

In many modern dairies a cold-storage room at 38° to 40° is provided, and milk placed in it when it does not go out immediately for consumption.

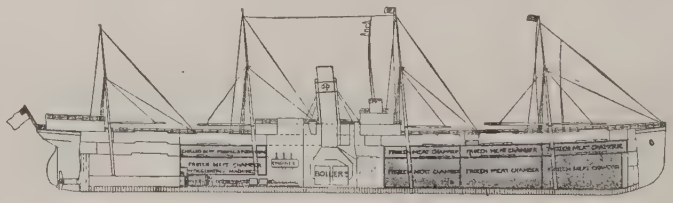
The revolving drums are made of hard rolled copper, tinned all over, and the milk troughs, which are round at the bottom, are made of the same material. There is, therefore, nothing that can contaminate the milk, and the revolving drums are thoroughly cleaned after use by being revolved while a brush is held against them, warm water being placed in each trough during the operation. This machine constitutes a pasteurising and chilling apparatus in one frame, but where the older types of pasteurisers are used the milk flows out from them over a flat cooler. These coolers reduce the milk to about 40° as it runs off into the large cans in which it is sent by rail.



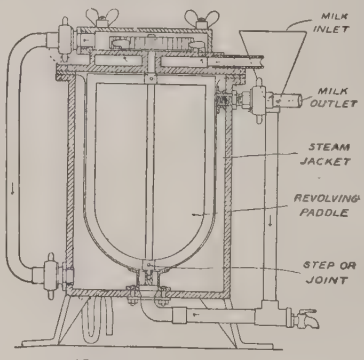
8. SECTION OF MARINE TYPE OF REFRIGERATING MACHINE

The Milk Refrigerating Machine. The next important item to consider in connection with milk pasteurisation and chilling plant is the refrigerating machine, which is necessary to produce brine at a low enough temperature to chill the milk to the requisite point.

We have already described machines worked with carbon dioxide gas. The one we shall now describe uses ammonia gas [12]. Any escape of gas is prevented by doing away with the reciprocating and compressor rod and stuffing-box, and by carrying the crank shaft horizontally through a self-sealing gland. The principle of refrigerating machines has already been explained. The gas enters at A through the pipe B, and thence into the piston C. D is the suction valve through which the gas passes as the piston descends; then, as it ascends again, the gas is compressed and driven through the passages F and up the discharge pipe F, into the condenser coils, HH, where it is cooled by the surrounding water and liquefied, collecting in a receiver. The liquid then flows to the expansion coils in the cooling apparatus, where it produces the desired refrigerating effect in the action of boiling off to gas again. The ammonia gas thus obtained is returned to the machine to be again liquefied, and the cycle is repeated.



9. SECTION OF A SHIP, SHOWING REFRIGERATING CHAMBERS



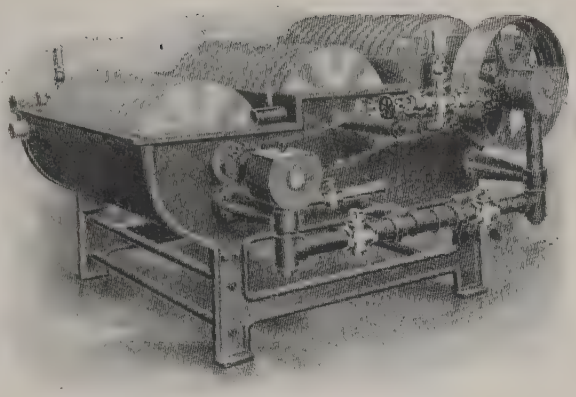
10. MILK PASTEURISER

The machine is actuated by the pulley P, attached to the crank shaft L, which revolves in an oil bath and also seals the packing joint M.

In larger machines the condenser is placed apart from the compressor, as a plant would otherwise be too bulky and cumbersome. It is built of two tubes, one placed inside the other; through the inner one runs the water which cools the ammonia compressed into the space between it and the outer tube. The construction of the coils is shown in **14**, and **13** is a view of the coil. This form of construction is far superior to the old type, where the ammonia gas was

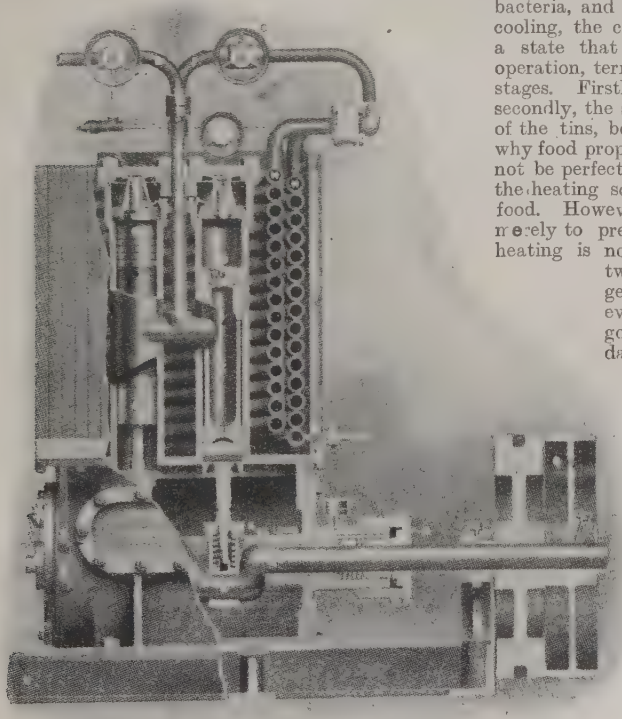
condensed in a flat coil of pipes, the gas flowing downwards inside the pipe and the water trickling downwards over the outside. The water in this case, being free to evaporate, brought about a certain lowering of temperature; on the other hand, the water getting warm in its descent ran over the bottom pipes when hottest, while the ammonia was endeavouring to liquefy inside these same pipes, with consequent re-evaporation of some of the liquefied ammonia and loss of efficiency.

The modern plant for dealing with milk mainly consists, therefore, of an efficient pasteurising machine and a simple and efficient refrigerating machine, with the necessary steam for the heating drum and the power to drive the pulleys on the pasteurising and refrigerating machines.



11. MILK PASTEURISING AND CHILLING APPARATUS
(The covers have been removed)

Removal of Dirt. Owing to the manner in which milk is produced, and at present handled at the farms, it seems almost impossible to exclude dust and dirt. An apparatus introduced within recent years is a strainer of exceedingly fine mesh, having about 1440 holes to the square inch. Such a fine gauze would be immediately stopped up if it were stationary and the milk simply poured through it. The strainer surface is therefore made in the form of a hoop, and is rotated as the milk flows through it. The rotating gauze hoop is constantly cleaned by a revolving brush, and passes under the milk in an open and clean condition. It is an established proof and fact that milk treated in the above-mentioned manner, properly cleaned, pasteurised and cooled, will keep about 18 hours longer under ordinary conditions than milk which has not been so treated. and it will keep in good condition for from seven to 10 days if placed in a cold room at 30°–40° F. The illustrations **10-14** have been supplied by Messrs. A. G. Enock & Co., Ltd.

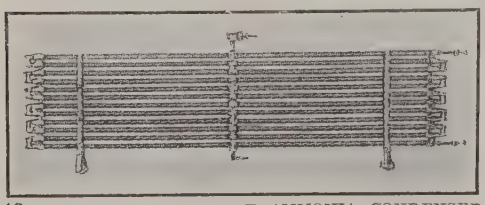


12. AMMONIA REFRIGERATING MACHINE

Tinned, Potted, and Bottled Goods. The method adopted in sterilising milk may be applied to numerous other foodstuffs. The principle of the canning process is simply this: The food is heated to about 170° F., in order to destroy bacteria, and the vessel sealed while hot. On cooling, the contents remain sterilised and in such a state that they will keep indefinitely. This operation, termed *processing*, is carried out in three stages. Firstly, the preparation of the foodstuff; secondly, the sterilisation; and, thirdly, the sealing of the tins, bottles, or jars. We know no reason why food properly prepared in this manner should not be perfectly harmless and nutritious, although the heating somewhat alters the character of the food. However, as it is the object of the packer merely to preserve and not to cook the food, the heating is not prolonged more than necessary, twenty minutes to half an hour being generally sufficient. There are, however, certain dangers common to canned goods. In the first place, there is the danger of the acid juices, especially in the case of fruits, having some action on the tin or solder, but cases of poisoning from this cause are very rare, and most of those recorded were probably due to quite another cause—namely, formation of ptomaines. At any rate, the danger can be easily avoided, if there be any, by using earthenware or glass vessels instead of metal ones.

Ptomaine Poisoning. The chief danger, however, arises from unsound tins, such as "pricked" tins—that is to say, tins inefficiently closed down, or which have been damaged so that the air has gained access to the contents. Tins are sometimes found "blown." This is owing

to incomplete sterilisation, bacterial action setting in after sealing, with the production of gaseous substances, causing a pressure inside the tin. There is always a partial vacuum in sound tins, so that when opened the air rushes in to them with a peculiar sound. If the tin has been imperfectly sealed, or if the sterilisation has not been complete, bacterial action is sure to set in, with the



13. COIL OF DOUBLE-TUBE AMMONIA CONDENSER

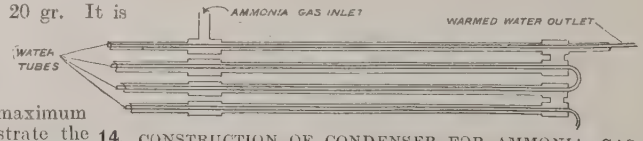
result that the extremely poisonous bodies, ptomaines, are produced. These are the causes of most cases of poisoning from eating tinned goods, especially tinned meat and fish, which are particularly liable to undergo such putrefactive changes. Sometimes, in the preliminary treatment, the foodstuff is treated with chemical preservatives in order to cover defective canning. This practice is to be condemned unhesitatingly, for if the canning be efficiently carried out there is no need for such preservatives. Chemical preservatives are, however, used very largely in food not destined to be canned, especially such as easily undergoes decomposition and putrefaction. We shall have to consider these chemical preservatives somewhat in detail.

Preservatives in Common Use. Common salt is about the oldest preservative we know of, but at the same time it is very ineffectual. In most cases large quantities are required. Where used it is often supplemented by the addition of some powerful preservative. Of chemical preservatives, borax and boracic acid are perhaps more commonly employed than any others. They are, however, very mild in their action, and the quantity used must not be too small. Numerous experiments have shown that less than 4 gr. to the pint is practically useless in preserving milk, and the quantity often recommended to be added is quite double this. Borax and boracic acid are also used largely for butter, cream, potted meat, and many other foods, and the question naturally arises whether they are harmful, and whether restrictions should be put upon their use. Boracic acid is frequently administered medicinally, the maximum dose being 15 gr.; that of borax is 20 gr. It is evident, therefore, that in the case of young children and invalids, who practically live on milk, the quantity taken daily, even putting it so low as 4 gr. to the pint, would exceed the maximum pharmaceutical dose. Such cases illustrate the danger which may attend its use. On the other hand, it is difficult to say how far it would affect a healthy adult, although elaborate experiments of Dr. Wiley some years ago seemed to show that even in that case it is likely to prove harmful. Nor can it be claimed that its use is necessary, as some of the largest wholesale dairymen bring their milk to London and other large towns from great distances, and manage to dispose of it without the use of any preservative whatever. Much the same considerations apply to butter, but we must bear in mind that it is not consumed to the same extent as milk by infants and invalids; and as to cream, the great difficulties in the way of preserving cream, even for a short while in the hot weather, make the use of a preservative pardonable. There is, however, no need for the use of any preservative in the case of meat or fish, which should be kept fresh by cold storage or other means.

Preservatives to be Avoided. Passing now to *formaline*, another preservative, we are on somewhat different ground. No one can assert that formaline is harmless, and its use as a preservative should be prohibited. Nevertheless, it is occasionally found in milk, and is sometimes sprayed over meat, fish, and fruit to preserve them. It has a peculiar action on the gelatinous constituents of foods, hardening them and rendering them insoluble, and thus very difficult to digest. *Salicylic acid* is another preservative, found especially in preserved fruits, temperance beverages, sacramental wines, lager beer, etc. It is probably more dangerous than borax, and its use is seldom, if ever, justified. People differ very much in their susceptibility to salicylic acid. Many people—according to some authorities, 60 per cent.—are easily affected by small doses of the drug, causing symptoms known as salicylism, including deafness, headache, delirium, etc. The use of salicylic acid in food should, therefore, be regarded with great suspicion. *Sodium sulphite* is another chemical preservative which is occasionally found, especially in stale meat, as it has the peculiar property of imparting the bright red colour of fresh meat. It also acts as a deodorant, and masks the offensive odours which are produced in the first stages of putrefaction. *Fluorides*, usually sodium or potassium fluoride, have been found in butter, and their use should be prohibited.

Frauds on the Public. With regard to all these chemical preservatives, the weaker ones, in small quantities, are not of very great value, and the stronger ones are dangerous. Moreover, their use must be regarded as a fraud upon the public, as they impart to the foodstuffs a deceptive appearance of freshness. Thus borax or boracic acid, although they have a certain inhibitory power on the micro-organisms, which bring about the souring of milk, probably have little or no effect on the more dangerous pathogenic bacteria, so that milk preserved with borax, although it may appear still fresh and palatable, is, nevertheless, as stale as if it had gone sour.

Unfortunately, legislation, as it affects preservatives, is extremely unsatisfactory in this country. Although the report of the Departmental Commission appointed to deal with this subject made



14. CONSTRUCTION OF CONDENSER FOR AMMONIA GAS

certain recommendations as to what preservatives should be permissible, and in what proportions, these recommendations have not been adopted by the Board of Agriculture, and have consequently remained a dead letter, with the result that conflicting decisions in the courts are the general rule.

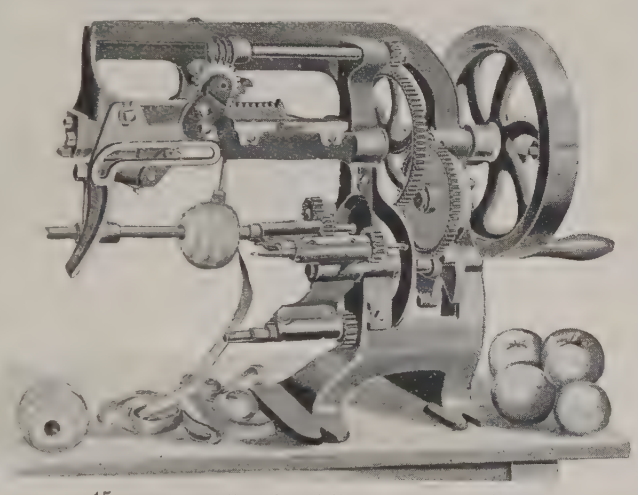
FRUIT PRESERVING

The importation of fruits into Great Britain, not deducting re-exportations, aggregates about 16 million tons, a good proportion of this quantity being used in making jam. To this supply must be added the fruit produced from the 84,000

acres devoted to small fruit growing in Great Britain, and which does not figure in any fiscal statistics. The number of jam factories in Great Britain is estimated at from 190 to 200, and this does not take any account of the quantity of jam, large in the aggregate, that is made in thousands of households, especially when fruit is cheap.

The Demand for Fruit. The public demand for fruit and preserves in enormous, and each year sees an increase in the acreage devoted to fruit-growing. The cultivation of apples for cider-making is also a growing industry, but the increase in acreage already alluded to is accounted for almost entirely by land devoted to other varieties of fruit. Jam-making is really the result of cheap sugar, and many of the larger factories have grown up within the last quarter of a century. The fruit imported into Great Britain comprises the dried fruits, such as currants, raisins, and prunes, together with fresh fruits, such as oranges, lemons, apples, and pears, fruit pulp, and candied fruits.

Oranges and Lemons. Oranges and lemons are the most easily marketed fruits. They come from the Mediterranean coast, China, the Azores, Mexico, Australia, and California. The oranges are gathered when not quite ripe, those fully formed and with the colour just turning from green to yellow being selected. Careful handling is essential, since rough handling results in bruising. The oranges are simply wrapped in fine paper or in the husk of Indian corn and put into boxes, the sides of which have air spaces. Lemons keep better than oranges, and are less liable to injury during the voyage. The greater part of the lemons grown are used as a source of citric acid.



15. NEW CENTURY APPLE-PARING MACHINE
Sprague Canning Machinery Co., Chicago

Currants and Raisins. Currants, the dried seedless fruit of a dwarf variety of grape vine, are produced in the Ionian Islands. The currants when sufficiently ripe are gathered and placed in layers exposed to the sun, being turned from time to time, and swept into heaps. When drying is complete the stalks have become detached. The currants are then separated from the débris and packed into casks for exportation.

Raisins are also a product of the grape vine, and are grown in Spain, Italy, Greece, the South of France, and California. The grapes are left on the vines after they have come to maturity, and the autumn sun is relied upon to do the necessary drying. Another way, and one practised in the newest raisin-growing districts, is to cut the bunches of grapes from the vine, and place them in shallow trays 2 ft. wide, 3 ft. long, and 1 in. deep. The raisins are then sun-dried, being turned from time to time by inverting a full tray on an empty one. The average time of drying is three weeks, depending, obviously, upon the weather. After the raisins have been dried they are stored in "sweat" boxes until ready for packing. To avoid delay in drying and any risk of getting the fruit wet through showers, some large growers have curing-houses, where the drying is finished after the raisins have been party sun-dried. Sun-dried fruit is far superior to that partly dried by artificial means. The drying-houses in use in Spain consist of a chamber 25 ft. long, 15 ft. wide, and 10 ft. high, the heat being supplied from a furnace outside, and conveyed throughout the building by a 9 in. flue. There is a vent for air at each corner. The temperature must not exceed 120° F., the most suitable for ensuring good fruit being 100° F. Some exposure to sunlight is absolutely necessary in drying raisins.

Why Raisins Look Glossy. In some parts of Spain and France the raisins are dipped, previous to drying, in a weak *lye* from wood ashes, to soften the skin and give the raisins a clear, glossy appearance. Drying is much facilitated by the preliminary dip in alkali. The dipping bath used for Valencia raisins is made by mixing the following ingredients: Wood ashes, 10 lb.; sulphur, ½ lb.; olive oil, ½ pint; water, 8 gals. Stir the ingredients together and allow to settle. The solution is then transferred to a cauldron, and heated to nearly boiling point before dipping the raisins. Occasionally, the dipping is dispensed with, the liquid being distributed over the fruit by means of a whisk. The method recommended by the Victoria Department of Agriculture for making pudding raisins is to dip the grapes, as soon as gathered, into boiling lye, made by mixing 1 lb. of Greenbank concentrated lye with 15 gals. of water. The fruit is immersed for from 20 to 30 seconds, the effect of the lye being to break the skin into minute cracks, and so facilitate the escape of moisture in the subsequent drying. The dipped fruit dries in from eight to twelve days in bright weather.

To give the fruit a bright amber colour, much preferred by the housewife, a sulphuring process is employed. The trays of raisins are stacked in a small chamber and exposed to the fumes of burning sulphur for from 40 to 50 minutes. The sulphuring has the effect of bleaching the dark colour, and increasing the value of the fruit in the market. Stemming (removing the stalks) and grading are performed by a simple machine, and two home-made wire sieves of ⅝ in. mesh and ¼ in. mesh answer perfectly when large quantities are not being treated.

Dates. Some varieties of dates require practically no curing, being ready to pack and ship as soon as they have ripened. Other varieties, however, need some preparatory treatment. Dates are borne in bunches, which have a single stem with numerous slender twigs, to which the fruit is attached. A bunch carries from 10 to 30 lb. of fruit. It is very rare that all the dates on a bunch ripen at the same time; and in the case of choice varieties, those which first ripen are often hand-picked, and shipped at once, in order to get the high prices paid for the earliest consignments. It is also claimed that picking the outer dates of the bunch, which usually ripen first, permits the inner fruit to ripen better. Frequently, when most of the dates on a bunch are ripe and the rest are beginning to ripen, the whole bunch is cut off and hung up in a dry and shady place. In a few weeks the whole bunch is ripe and ready for shipment. The choice varieties of dates are shipped from the Sahara, either in bags or long, wooden boxes, and afterwards repacked in smaller boxes. The above methods apply to the Deglet Noor variety, which is chiefly exported from Algiers. The Rhars variety, which is full of sugary juice, is not so easily handled. The Arabs usually hang up the bunches, and allow the juice to drain off into jars. This juice is called *date-honey;* and when it has drained off, the fruit is ready for packing into boxes or skins. When packed tightly, dates keep for years without any deterioration in quality.

Prunes. Prunes are simply dried French plums. The best kinds are sun-dried after careful selection for quality. The plums are allowed to ripen thoroughly before being gathered.

The alternative process used in some districts involves the use of a lye-bath, as for raisin-curing, to soften the skins and facilitate the drying. The softening in other cases is done by half cooking the dried plums for from two to three minutes in water to which glycerin, in the proportion of 1 lb. to 20 gallons, is added. The plums are then dried for three or four days, and then packed in glass bottles that are tightly sealed. The lighter-coloured prunes are submitted to a sulphuring process.

Figs. Figs come chiefly from Asiatic Turkey, though Portugal, Spain, and Greece send small quantities. The figs are allowed to drop from the trees; the fruit does not bruise, because it is dry. The figs are then exposed to the sun on dry grass for three or four days. Smyrna is the centre of the fig-producing district, the growers bringing in their produce in sacks. Damp is injurious in the drying process, and the pre-eminence of Asiatic Turkey is due to the climate being perfect for fig-drying. In Spain the climate demands that the figs must be covered up with boards or canvas during the night, or they would spoil.

Desiccated Fruits. Desiccated fruits include dried apples, apricots, and peaches. It is questionable whether the demand for dried apples is so large as formerly, as the preference is naturally given to the fresh apples now obtainable all the year round. Apples for tarts are now also to be had, at very reasonable prices, packed in water. The *dried apples*, or *apple rings* as they are called, have, however, the advantage of cheapness, and when rejuvenated by soaking in water are a really passable substitute for the fresh fruit. The apples are pared, cored, and sliced by machinery, one of the machines being illustrated in **15**. As soon as peeled, the apples are dropped into salt water, and after a few minutes' immersion are put in the sulphur-box, and fumed for from 30 to 35 minutes. The slices are then spread on trays, and placed in the sun for four or five days, being turned once. When artificial drying is employed, a chamber or evaporator supplied with a current of air at 240° F. is used. The trays of apple slices are taken through the evaporator on an endless chain, moving every three or five minutes. A bushel of apples makes 5 lb. of dried fruit. *Apricots* and *peaches* must be thoroughly ripe and well coloured before being gathered. They are then pared, halved, and stoned by simple appliances, and placed on wooden trays, cut side up. Drying takes five or six days in the sun, and is often preceded by sulphuring. As neither of these fruits is grown in Great Britain to any extent, there is considerable demand for the dried articles. Passable jam can be made from dried apricots, the proportions being 2 lb. of dried apricots, 5 lb. of sugar, and 8 pints of water. The apricots are covered with water for five minutes, and drained, 8 pints of water being then added, and allowed to remain in contact for 12 hours. Next transfer to an enamelled pan, boil for five minutes, add the sugar, again boil for fifteen minutes, and put into pots.

Canning and Bottling. Canning fruit is distinctly an American process. The English term would be *tinning*, but as the association of a metal with a food is apt to convey a bad impression, it is perhaps as well that the American term *canning* is used. Bottling of fruit is, of course, merely a development of canning, the primary reason doubtless being that glass is supposed to be preferable to tin for food containers, which, however, is not the case, for the lacquer with which the insides of the tins are coated renders them perfectly free from any danger of affecting the fruit or syrup or water in which it is preserved. The underlying principle of canning and bottling fruit is that the contents are sterilised, and then preserved in a hermetically sealed vessel. The temperature of 170° F. has been found to be the correct one to use in sterilising, but the time taken for this temperature to penetrate to the centre of the vessel containing the fruit naturally varies according to the size of the vessel and the kind of fruit which is being sterilised. The fruit must not be heated sufficiently long to cook it; hence care is necessary in the temperature employed, if successful bottled or canned fruit is to be produced. The "A. B. H." thermometer is used to ascertain the sterilisation point of the interior of a bottle of fruit. A similar thermometer is also applied to cans. Fruit is canned in either water or syrup. If syrup be employed, it is poured over the fruit as it boils, and consequently the time taken for sterilising is shorter. The general formula for canning fruit is as follows: Carefully select and prepare the fruit, place in the tins, and cover with cold or boiling water; seal the tin so that it is air-tight, and sterilise (or *process*, as canners generally call it). The average times are: For small fruits, such as cherries and small plums, pint size cans, 8 minutes; quart size, 10 minutes. For large fruits, such as peaches and apricots, pint size, 10 minutes; quart, 12 minutes. These are for fruits with the stones left in. When the stones have been removed a shorter time is required, as the heat is conveyed to the interior more quickly—for pint cans, 6 minutes, and for quarts, 8 minutes, are average times.

Preliminary Treatment for Preserving. Apples and similar fruits require paring and coring, as for making dried apples, but are

not sliced. Pack as tightly as possible in the containers, fill with boiling water, seal and process. The time required is that given for stoned fruit. A difficulty met with in canning apples is the discoloration of the fruit. To obviate this, some makers put the apples, after peeling, into a solution of sodium sulphite (1 oz. to 4 gallons of water), or a solution of alum of the same strength. When syrup is used, it is of the strength of 18° B., and is often flavoured with lemon.

Pears are treated in a similar manner to apples, but are often more difficult to keep white. If the result desired be not obtained by the treatment given above for apples, the peeled and cored pears are exposed to the gas given off from burning sulphur for three or four hours.

Cherries have their stones removed by means of a *pitting* machine, are then put into bottles, covered with water, sealed, and processed. The cherries used should not be ripe, and the water for filling the bottles is generally coloured with cochineal, as the public prefer a brightly coloured product.

Greengages are pricked to prevent bursting, a silver or copper needle being employed. The water is often tinted green with a little emerald-green. Plums are pricked, but no tint is needed.

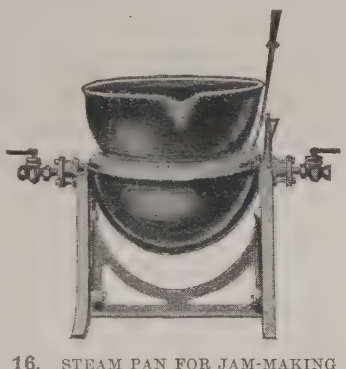
Gooseberries are bottled when green.

Apricots and peaches are cut into halves and pricked, the stones also being removed. Syrup is always used for these fruits. Whole apricots are also canned.

Rhubarb is bottled when tender and young. It is cut into pieces about 1½ in. long. Water is used in the bottles.

Bananas are bottled in syrup to which glucose has been added in place of sugar. The syrup is generally flavoured with vanilla or lemon, and to improve the taste a little citric acid is added.

Red currants are removed from the bunches with a nickel, silver, or celluloid comb.



16. STEAM PAN FOR JAM-MAKING
William Brierley, Rochdale

Blackberries require very careful picking over to remove leaves and refuse. For this purpose they are spread out on a table in front of the operator, a good light being essential.

Raspberries and strawberries are not often successfully canned unless they have been previously candied—that is, if it is desired to retain their shape. The big preservers, who have expensive plants and particular facilities, are able to can and bottle the fresh fruit.

Pineapples are peeled by machinery and sliced, care being taken to remove all the "eyes." This fruit takes two hours to process, at the temperature of boiling water, on account of its bulk.

Crushed fruits, so much used for soda-fountains in the United States, are prepared by crushing or grating the fruit, which is then heated with boiling syrup at 28° B. for three minutes, then transferred to tins or bottles, and processed for a time varying from 10 minutes for pint containers to 40 minutes for gallon tins.

Pulping. Fruit pulp is fresh pulp preserved without sugar; it is, in fact, a sterilising process of keeping fruit. Large quantities of fruit pulp are imported into Great Britain, and used for making jam. All the apricot jam made in Great Britain is necessarily made from imported apricot pulp, as but few apricots are grown in this country. Pulped fruits are a little inferior to ripe fruits for jam-making, and hence pulps are only used in medium and cheap jams. The difference, however, is mainly in appearance, and does not affect the wholesomeness of the product. The addition of colouring matter to jams made from pulps is required to give a nice appearance. A great deal of fruit pulp of various kinds is imported from the Continent and from America.

The process of fruit-pulping is, in outline, to add 32 oz. of water to 20 lb. of the fruit, boil for five minutes, put into gallon or two-gallon tins, and process for from 2½ hours to 3½ hours (for gallon tins) at the temperature of boiling water. The tin should be lacquered to prevent possible metallic contamination and discoloration of the pulp.

Apricot pulp is made from ripe fruit which has been stoned, and a little more water is added than is given in the outline process above. The stones from the apricot are used for flavouring purposes, and should not be thrown away. Peach pulp is similarly prepared. Greengages are stoned, and in the preliminary boiling should not be violently stirred, as the fruit would be broken up too much. Cherry, strawberry, and black currant pulp present no difficulties, except that in the case of strawberries the preliminary boiling is limited to two minutes, on account of the soft nature of the fruit.

Jam-making. Jam is usually described as a conserve of fruit boiled down with sugar. There is no standard for jam. Each jam-maker has his own modification of the old formula —1 lb. of fruit to 1 lb. of sugar —the test of a good product being the appreciation of the purchaser. It is, of course, understood that wholesome ingredients must be used in every case. The employment of wet or damaged fruit for jam-making brings in its train a multitude of consequences which soon injure a jam-maker's reputation. The solidifying property of jam is due to the sugar and to the pectose contained in ripe fruit. The pectose, by boiling with vegetable acids, such as are also contained in the fruit, yields a product known as *pectin*, which possesses solidifying power like gelatin. Prolonged or violent boiling destroys the pectin, and hence impairs the solidifying powers of the jam. On the large scale, steam pans [**16**] are used.

The general formula given above is the one on which the manufacturer founds his process, except that the boiling, which in the case of domestic manufactures may be up to two hours, is by steam pan process cut down to 15 or 20 minutes, the product being superior, as regards flavour and appearance, to the domestic article. Crystal sugar, equal in quantity to the fruit, is added, the mixture being boiled to dissolve the sugar. The contents of the pan are stirred, and if glucose be used it is added in place of part of the sugar. The second or medium grade jam is made from fruit pulp, and a cheaper grade still is made by boiling fruit pulp 100 lb., sugar 30 lb., and glucose 70 lb., till dissolved, and adding towards the end of the process 1 lb. to 1½ lb. of agar-agar dissolved in the smallest quantity of water. The jam is poured into the earthenware

or glass pots direct from the pan, and when the product has set the surface is covered with a disc of waxed paper, previously dipped in spirit. The wet parchment cover is stretched over the top, and fastened so as to exclude air.

The Making of Special Jams. Strawberry jam is made from the freshest fruit, for if the strawberries stand over-night the colour of the jam is not so good. The Wisbech district, Kent, and Cornwall are the strawberry-growing parts, the Cornwall strawberries being the earliest in the market. Raspberries are grown extensively near Yarmouth and at Blairgowrie. The crop of raspberries of late years has been poor, but it may be mentioned as a hint to growers that in Scotland the favourites are Maclaren's Prolific and the Red Antwerp, while farther south the best varieties to grow are Superlatives, Carter's Prolific, and Semper Fidelis. Raspberry jam is a difficult one to set, and for this reason a portion of gooseberry or apply jelly is often added to it. Black currants come in large quantities from France, Holland, and Belgium; and on account of the ravages of the black currant "mite," imports of the fruit are necessary to meet the demand. Blackberries are preserved with apples, and such jam is in increasing demand. The blackberry crop is a difficult one to get picked, and fetches from £10 to £20 a ton. As regards plum jam, although plum pulp is not imported, for reasons stated above, immense quantities of plums reach this country from the Continent, in seasons of scarcity coming even from so far afield as Hungary. French and German plums come in some three weeks before the English plums are ripe for the market, but are not superior to English fruit. The advantage which foreign fruit enjoys over home grown is that large quantities of a particular kind of plum—such as the Zwetchen—can be obtained, whereas the English plums are from various kinds of stock. When home-grown plums are plentiful the foreign article cannot be profitably imported, as it costs £7 10s. a ton to import foreign plums, and an English grower is satisfied to get £7 in times of plenty. Greengages nearly all come from Cambridgeshire. Damsons are very largely grown near Wrexham for jam purposes; and although the popular taste has shifted from damson to plum jam, there are still large quantities of damson jam sold in Lancashire.

Kind of Sugar Used. In manufactured jam there is about 55 per cent. of sugar. The sugar may be either the product of the sugar cane or the beet. [See SUGAR.] There is practically no difference in the respective values of these sugars, so that the cheapest should be used. Glucose was for a time used by many jam manufacturers, but there is now a popular prejudice against it, and it is used only in the common kinds of jam. When sugar is boiled with a weak solution of a vegetable acid, it is changed into "invert" sugar, then into dextrose and levulose, and finally into glucose.

Jam Colouring. As has been noted in the section devoted to pulping, the colour of the product is impaired, so that when made into jam a colouring matter is needed. Pink is obtained by the use of carmine (the active principle of cochineal), and a wine-red by means of cudbear.

Aniline dyes, rhodamine, and rosaniline are sometimes used, the quantity needed being but 5 or 10 grains in a hundredweight of jam. The colour is added in solution during the early part of the process of jam-making. As yellow colours, sometimes added to apricot jam, saffron-yellow and auramine (aniline dyes) are used. In regard to the use of preservatives, salicylic acid is employed in the proportion of ½ oz. to 1 cwt. of jam. It is added in the form of powder at the beginning of the process, the boiling of the jam being sufficient to ensure mixing. Owing to the minute quantities of the aniline dyes required, no harm results from their use.

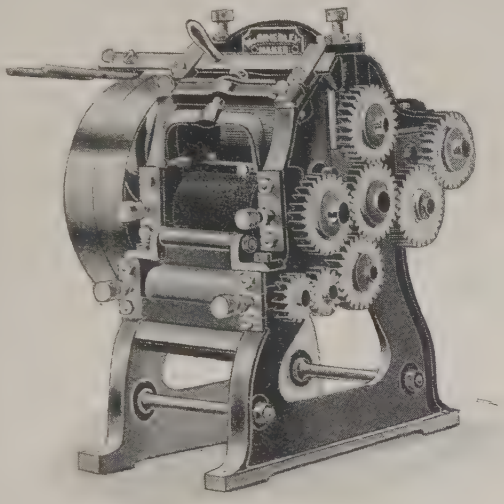
Fruit Jellies. Fruit jellies are transparent preparations of the juices of fruits, and are used to supply or make good the deficiency of the setting power of raspberry, strawberry, and black currant jams. Some jellies are, however, largely used in place of jams, while red currant jelly has a special purpose in the cuisine as an adjunct to roast mutton and hare. The fruits from which jellies are mostly prepared are apples, gooseberries, grapes, black and red currants, and blackberries. The process is to mix three parts of fruit with one part of cold water, and boil. The mass is then transferred to filter bags, and the juice is finally heated to boiling point and poured into stone jars which have been previously scalded to destroy fermentation germs. Fruit jellies are made by adding to each pint of juice a little over a pound of sugar, and boiling till a small quantity of the product, removed and cooled on ice, sets to a jelly.

Marmalade. Marmalade is an orange jam, although originally the name was applied to a quince jelly, *marmelo* being the Portuguese for quince. It is now rarely made from quinces, but oranges, lemons, and grapes are used. Originally, marmalade was made with honey, but now sugar is the base employed. Orange pulp is imported from Spain for the use of marmalade makers, but all the best manufacturers use the fresh Seville oranges. Machines are sold for the special purpose of cutting up the orange and lemon peel. A good *domestic marmalade* is made by using both bitter and sweet oranges with lemons. For instance, six bitter oranges, three sweet oranges, and two lemons may be taken, the peel removed, with a minimum of white, cut up, and boiled with nine pints of water until soft. The rest of the fruit is pulped and the juice expressed, and in the mixture of juice and peel infusion 9 lb. of sugar is dissolved, and the whole boiled until jellying takes place on cooling a little of the mass. For making marmalade on the large scale, oranges are peeled, freed from pips, the peel sliced and cut up in pieces by a machine [17], and the rest of the orange reduced to a pulp; to 20 lb. of this pulp are added 30 lb. of sugar and ½ gallon of apple juice, the cut-up peel introduced, and the whole boiled slowly for an hour. After this further boiling is given at a more rapid rate till the product jellies on cooling. It is obvious that the oranges may be mixed, as in the recipe for domestic marmalade. *Orange marmalade* of the jelly class is made by excluding the orange pulp, using only the juice. A French recipe is as follows: Orange juice, 5 pints; apple juice, 15 pints; syrup, 10 pints; sugar, 5 lb.; finely sliced orange-peel, 5 pints. These ingredients are boiled together till the marmalade sets to a jelly on cooling. *Grape marmalade* is really a fruit jelly, and is made according to the method described in the section devoted to fruit jellies.

Candied Fruits. Candying is a refinement of the preservers' art, and is applied to cherries, strawberries, greengages, small oranges and pears, to lemon, orange, and citron peel, and to angelica. The fruits are prepared as for bottling, and finally dried on trays made of white willow. A stoneware tank is employed, the fruits being packed in it

and covered with weak syrup. After being in the syrup overnight the syrup is withdrawn by means of a stopcock at the bottom of the tank, and concentrated by boiling and adding more sugar from, say, 20° B., at which it was used first, to 22° B. This syrup is then poured over the fruit and left for two or three days, drained off, and again concentrated, the process being continued till the syrup registers 33° B., when it is drained off and the fruits taken out and dried slowly in a warm room. Finally, if the fruits be not covered with fine crystals of sugar, they are crystallised by pouring over them, on a wire tray, a syrup of 33° B. strength, made from pure sugar, drained and dried. *Glacé fruits* are produced by giving the fruits at the end of the syruping process a few minutes' boiling in syrup and removing them to a wire tray to dry slowly. A small proportion of glucose may be added to the syrups used in candying fruits, and colouring matters may be introduced if needed. A hot process is also employed, in which the fruits are boiled with the successive syrups. Besides being eaten for dessert, candied fruits are used for preparing superior kinds of jam. Candied strawberries and raspberries are excellent when made into jam with apple juice. Candied cherries are covered with maraschino-flavoured spirit to make "cherries in maraschino," and Wiesbaden fruits are candied fruits put up in strong syrup. For testing the strength of the syrups a hydrometer is used.

The Factory. The ideal arrangement of a factory is such that the workmen are kept employed all the year round. Hence, factories which make jam should can vegetables and make pickles, etc., to fill in slack months. It is consequently difficult to give trustworthy estimates of the cost of equipping a factory until the extent of the trade to be done is stated. The machinery for a small factory costs anything from £200 upwards, according to the branches of canning pursued and the amount of business done. Some of the costs of machinery used in canning are stated below, to give an idea of the expenditure in fitting up a factory.



17. HOME-MADE MARMALADE MACHINE
William Brierley, Ltd., Rochdale

Copper steam-jacketed jam-boiling pans, suitable for working at a pressure of 70 lb., and with a capacity of 45 gallons, cost from £17 to £35.

Tanks for bottling fruit are made of iron with false bottom for standing the bottles on, under which is the heating coil. The cost of a tank 7 ft. long, 2 ft. 9 in. wide, and 18 in. high is £16 16s.

Apple-paring machines cost £1 10s. to £5, according to the pattern. An *apple slicer* of simple design costs 16s., the more complicated varieties running to £15.

A *marmalade machine* for stripping the white from orange-peel and cutting into strips costs from £15 to £50. A *pulping machine* for fruit costs from £10 10s. to £40.

A *hydraulic press* for extracting the juice from apple pulp by hand power entails an outlay of £50; for £5 extra it can be adapted to power.

Platform scales for weighing large quantities of fruit or sugar cost from £2 to £10.

Horizontal boiler complete costs from £100 for a 10 h-p. boiler.

Hydrometers for testing the strength of syrups cost 4s. 6d. each.

Thermometers for taking temperature of water, etc., cost 10s.

Factory trucks cost from £1.

Hoist, of a capacity of 1000 lb., costs about £15.

Soldering irons cost from 3s.

Peeling knives cost 3s. 6d. a dozen.

CONDIMENTS

Although eaten with foods, condiments cannot be regarded as true foods, as their food value is almost negligible, many (such as pepper, mustard, and spices) being largely composed of indigestible fibre. They may, however, be regarded as adjuncts to food, and are taken in comparatively small quantities, with the idea of stimulating the appetite. Most of them contain a small proportion of a very active ingredient. Thus pepper contains a resin, "piperin"; mustard, a volatile oil; and spices similar oils, which give to the condiments their peculiar flavours. These active ingredients are so powerful that they would act as poisons if taken in really large quantities. Acetic acid, too, can only be taken in the diluted form as vinegar. In virtue of the chemical nature of the active ingredients, many condiments act as food preservatives, especially salt and the spices.

Common Salt. Although most condiments can hardly be regarded as necessities, common salt is certainly an exception. It is one of the essentials for our health preservation.

Nature has endowed this country with salt supplies second to none, both in quantity and quality. Salt is brought to the surface either in the form of clear liquid, as *brine*, or as dry rock, known as *rock salt*. Cheshire brine yields for every imperial gallon 3 lb. 2 oz. of dry salt. Roughly, 1000 gallons of brine produce a ton of dry salt.

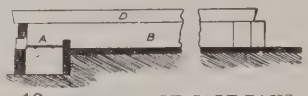
The brine is said to run under the earth in channels, and to collect in the lowest part of the geological basin at a depth of about 130 ft., whence it is pumped to the surface. It is supposed to result from the rain-water percolating to the rock salt and dissolving it. Where fresh water reaches the surface of rock salt, either at the outcrop or through fissures in the outlying marl, brine is formed.

The brine has the following average composition :

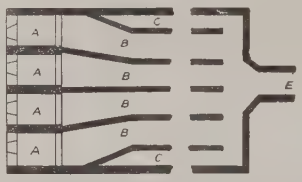
Substances	Northwich	Droitwich	Stoke Prior
	Per cent.	Per cent.	Per cent.
Sodium chloride ..	25·222	22·452	25·492
Calcium sulphate ..	·391	·387	·261
Sodium sulphate ..	·146	·390	·594
Magnesium carbonate	·107	·034	·034
Total solids ..	25·866	23·263	26·381

Brine is pumped by two plungers from a depth of 64 yds. through an 8-in. pipe, and delivered to an enormous wooden cistern measuring about 36 ft. by 32 ft. by 10 ft. deep. From this tank the brine passes through pipes to the evaporating pans.

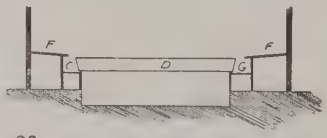
The Salt-pans. The pans are made of steel, measuring about 36 ft. by 24 ft. by 20 in. deep, rest on brickwork, and are heated underneath by coal fires. A battery usually contains from five to ten pans. For examples of ordinary pan settings, see **18, 19,** and **20.** This type of pan has one flue, B, for each fireplace, A, and blank spaces, C, over which the salt in the pan can be scraped to the side without fear of overheating. D is the salt-pan, and E the flue to drying-room ; F F the hurdles, and G the floor, on which the workman stands. Each pan in the particular works we are describing has two fires, divided by a partition wall running half way to the back of the pan. In order to ensure even distribution of heat, there are five draughts, as they are called, divided by four parallel walls running half way from the back. Brine is conveyed continuously to the evaporating pan, gentle ebullition takes place, and enormous volumes of steam pass off from the surface and disappear up the ventilators in the roof. The temperature of the brine is maintained at about 220° F.



18. SETTING OF SALT-PANS
(Longitudinal section)



19. PLAN OF FLUES OF SALT-PAN



20. TRANSVERSE SECTION OF SALT-PAN

As the water evaporates, an incrustation of crystalline salt is formed on the surface, which, as it gets heavy, settles in the cooler end of the pan. The crystalline deposit of pure salt so formed is drawn to the side of the pan by means of a rake [**21**]. The salt is then lifted out of the pan by means of a skimmer [**22**], a perforated scoop about 18 in. diameter. The excess of liquid drains through the perforations, and the contents of the skimmer are transferred to a wooden mould consisting of an open box [**23**] tapering from one end to the other (length, 22 in. and 8 in. by 8 in. at large end), standing on its smaller end.

21. RAKE **22.** SKIMMER **23.** MOULD

Drying and Packing the Salt. When a number of moulds have been filled and allowed to set, they are inverted, tipped out, and conveyed to the drying-room. The ordinary size block weighs 28 lb. (80 to the ton). Each pan produces four tons in 12 hours (equal to about 50 tons a week).

The drying-room is heated by the waste heat from the furnaces, which passes through long, square, iron flues, 4 ft. by 4 ft., placed on the floor level, on and around which the blocks are stacked. The temperature of the drying-room varies from 120° F. to 150° F. The blocks take six to fourteen days to dry, according to the temperature and weather. The dried blocks now pass through a munching machine, and then through a pair of rollers, and finally through sieves, until the required grain of salt is obtained.

The dry salt is carried by "elevators" to the top of the building, whence radiate, octopus-like, shoots or feeders, reaching to all parts of a large packing-room, where girls are busily employed filling *damp*-proof paper packets, which consist of two sizes, and contain 1½ lb. and ¾ lb. respectively of table salt. The salt is never touched by hand from beginning to end.

Preparing Fishery Salt. The preparation of salt for the preservation of food, such as fish salt, is made somewhat differently from that of table salt. It has to be coarse and distinctly granular for sprinkling between layers of fish in boxes or barrels, as, if too fine, it would melt too rapidly.

For *fishery* salt, the brine in the pans is evaporated at from 90° F. to 120° F., according to the quality to be produced. The lower the temperature, the slower the operation, and, in consequence the coarser the grain.

There are several qualities of fishery salt, distinguished according to coarseness. The first grade of salt is named Second Fishery, a degree coarser is Best Fishery ; next higher grade is X Fishery ; a still better quality is XX, and the highest of all, and the coarsest, is Bay Salt [**24**].

From 22 to 25 tons per pan per week is the average production of fishery salt.

The Salt Union supplies 90 per cent. of the salt used in Great Britain for fish-curing. The pans owned by them have a capacity of about 1,000,000 tons per annum.

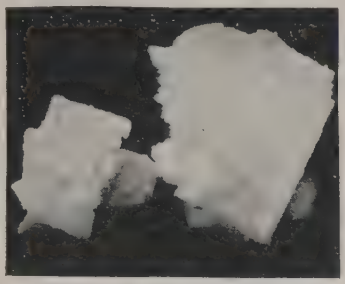
The attempt to oust the pure, natural article by salts obtained from sea-water evaporated by the sun's rays in hot climates is likely to end in failure, as, in addition to the great inferiority in composition of the latter, there is a liability to the formation of a fungus on fish which does not take place with the pure article. Sea-water also contains many organic ingredients that militate against the proper preservative action of salt.

The following analysis will show the difference in composition between the Cheshire fishery salt and the foreign sun-evaporated sea-water :

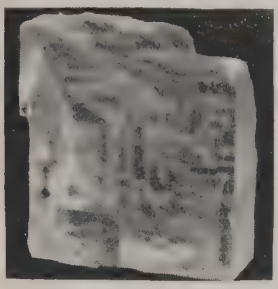
Ingredients	Cheshire Second Fishery	Foreign
	Per cent.	Per cent.
Chloride of sodium (pure salt) ..	97·32	89·21
Moisture	1·72	4·82
Sulphate of lime	·85	1·48
Sulphate of magnesium	—	3·15
Chloride of magnesium	·08	·95
Insoluble matter	·03	·39
	100·00	100·00

Where Rock Salt is Found. The geological position of rock salt occurs between the coal formation and the lias in the New Red Sandstone of the Triassic series. The great rock salt formation of England occurs within the red marl, or red sandstone. At Northwich, in the valley of the Weaver, rock salt is found in two chief beds, the top being about 87 ft. thick, and the bottom 90 ft. The top bed is 126 ft. below the surface.

The mining is done from the bottom of the layer of the thick bottom bed, where the best salt is found. The natural beds are about two miles long by one and a half miles wide.



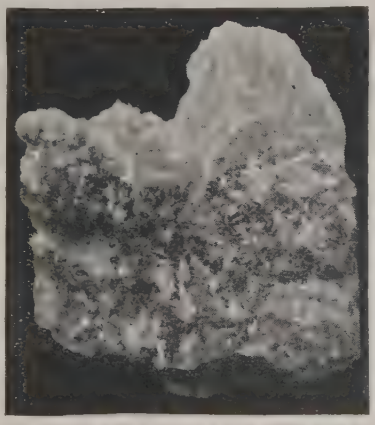
24. BAY SALT
(One-third scale)



25. SALT CRYSTAL
(Adelaide mines, one-half scale)

A Large Salt Mine. To support the weight above, it is necessary to leave pillars of salt equal to about one-twelfth the area of the mine. This is done by leaving enormous pillars (somewhat larger at the bottom than the top), 10 yds. square and 25 yds. apart.

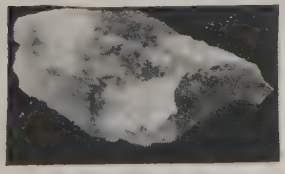
The rock salt raised as blasted from the Adelaide mines belonging to the Salt Union, Ltd., at Marston, Northwich, is called "Prussian Rock" when brought to the surface, and the larger pieces resemble enormous blocks of granite and porphyry. In places it contains veins of deep brown or amber colour [light portions, 26], grading to pale transparent salmon tint [dark portion, 26], and in some parts it is as transparent as glass and very pure, and crystallised in large cubes [25]. If taken at base of vein, one occasionally finds attached pieces of stone [see right-hand bottom corner of 27]. In other places the caverns are bristling with needle-shaped crystals not unlike the familiar sal-ammoniac [28], and in some few places it is opaque and white, falling to pieces between the fingers as though Nature had already prepared it for coarse fishery salt [29]. The mine at Marston is 336 ft. deep. It is approached by a perpendicular shaft about 9 ft. wide, by means of a bucket, which emerges into a cavern 30 ft. high. This cavern is the largest rock mine in Great Britain. Its walls and domes are bristling with crystals of rock salt in the various varieties referred to above. This chasm has entirely resulted from the removal of enormous quantities of salt rock, about and around which there still exist almost limitless supplies.



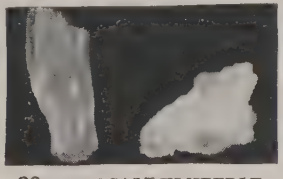
26. ROCK SALT FROM ADELAIDE MINES
(One-third scale)

The Mining of Rock Salt. In order to obtain the rock salt, a horizontal incision is made in the wall of the rock 7 in. from the base, the incision being 4 in. deep and 28 in. wide. This is performed by a machine resembling a very substantial circular saw with two-way teeth arranged round its circumference. The machine is driven by compressed air laid on to the mine, and is moved forward by means of a grab. The cut it made slightly downwards, so that the floor appears in ridges. The progress of the work depends largely upon the hardness of the rock, which varies considerably at different points. To prepare the rock to receive the charges for blasting, holes are produced by means of an iron pole, called a *chisel*, that is rod-shaped and tapering towards the end, which is beaten out to a spear-shaped head. This is thrust into the rock and turned until the required depth is reached. In this hole a charge is inserted and fired by the aid of a fuse. Sometimes the charges merely crack the rock, and at others they remove several tons. Thus, if large pieces are wanted, a small charge is put in vertically, by which the face of the rock is just cracked and the necessary sizes are removed with a pick. If small lumps are required, a large charge is put in in a slanting direction, which blows the rock to pieces.

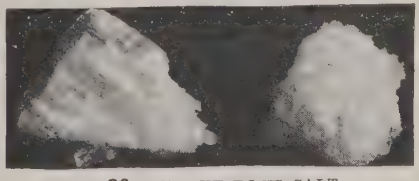
In addition to their mines at Northwich and Winsford, in Cheshire, the Salt Union have mines at Carrickfergus, in Ireland, and they have also white salt works at Northwich, Winsford, Middlewich (Cheshire), Stoke Prior and Droitwich (Worcestershire), Middlesbrough (Durham).



27. ROCK SALT WITH ATTACHED STONE
(One-half scale)



28. ROCK SALT IN NEEDLE-SHAPED CRYSTALS
(One-half scale)



29. OPAQUE ROCK SALT
(One-half scale)

The Uses of Rock Salt. The rock salt is ground to a powder and supplied in bags for agricultural purposes. It is exported in lumps for

refining and conversion into table salts. It is placed unground in the stalls of oxen, who greedily lick it as an adjunct to their food. Brine is used in large quantities in the "Solvay" process for the manufacture of alkali; white salt and rock salt in the "Leblanc" process for the production of soda and salt cake [see Acids and Alkalies], also in copper smelting. As such it forms the basis of several of our most important industries, which are dealt with at full length under different sections. Brine also plays a very important part in the process of refrigeration [see the early part of the chapter]. The following list gives the various other uses to which salt is put:

Scouring
Removing discolorations
Washing greasy bottles
Removing inkstains from carpets and tablecloths
Removing wine-stains
Carpet cleaning
Dissolved in spirit for removing grease-spots
Washing silk handkerchiefs
Mixed with oil for furniture polishes
Cleaning straw matting
Cleaning brooms
Disinfecting
Cleaning slimy sponges
Cleaning stained hands
Cleaning copper (with lemon added)
Making a fire to burn up
On frozen roads
Consolidating roads
Destroying insects in gardens
Destroying vermin in manure heaps
Weed klliing
Doctoring horses, cattle, and sheep
As food for cows to improve milking
With food for cattle to improve appetite and digestion
With poultry food
With all foods deficient in salt
As medicine
In brine baths
As an antidote to poisons, snake and dog bites
Improving the burning of paraffin
Preserving potatoes
Salting down vegetables before cooking
Removing animalculæ from raw vegetables, such as watercress
Salting butter
Bread making (added to flour)
Plugging tobacco pipes
Eating with fruit
Preserving meat
Extracting frost from frozen vegetables
Detecting poisonous mushrooms
Preserving milk
Preserving eggs
Curing hams and bacon
Fish curing and preserving
In liquid form, as a fire extinguisher
Laying dust.
Assisting disintegration and weathering of soil
Absorbing and retaining moisture on the ground, and therefore as a preventive of drought
Assisting the soil to absorb ammonia for crops
Purifying land
Placing on land to cause cattle to crop closer
Increasing clover crops
Checking or preventing potato disease
Sweetening and preserving fodder, and preventing mouldiness in it.

No distinction has been made between *stove* salt, etc., and *rock* salt in the above enumeration, but it may be taken generally that salt from brine is always used in connection with human food and household purposes, and ground rock salt for all others, except where colour and a high degree of purity are of paramount importance.

Natural Vinegars. Genuine vinegar has been defined as the "product of the alcoholic and acetous fermentation of vegetable juice or infusion." That is to say, it is obtained from some vegetable extract which is allowed to ferment, first with the formation of alcohol, which is then converted into acetic acid. Vinegar so prepared will consist of a solution of acetic acid with various vegetable juices and colouring matters. To this class belong the true malt vinegars, prepared from malt or a mixture of malt and barley. The materials are finely ground and *mashed*—that is, extracted repeatedly with small quantities of hot water till all soluble matters are removed. The clear liquors are run off into a vat, where yeast is added, so that fermentation sets in; carbon dioxide gas is given off, and alcohol formed in the liquor. This alcohol has to be further oxidised to form acetic acid, for which purposes some means is adopted to expose it effectually to the oxygen of the air. The action, however, would be slow were it not for the growth of a peculiar fungus, or "vinegar plant" (*Mycoderma aceti*). Either the liquor is allowed to trickle over twigs on which the vinegar plant grows, or the liquor passes through barrels on the sides of which the plant has developed. So prepared, *malt* vinegar has a peculiar and pleasant odour, due to the presence of small quantities of organic substances known as *aldehydes*, *esters*, etc., and it is coloured brown owing to the presence of organic colouring matters formed in the process. Small quantities of vinegar are also prepared from inferior wine, but very little prepared in this manner is met with in this country.

Artificial Vinegars. In contrast to these natural vinegars are the artificial *wood* vinegars, prepared by doctoring a solution of acetic acid obtained by distilling wood and small quantities of caramel, other substances being added to imitate the colour and appearance of *malt* vinegar. A great deal of the vinegar sold is prepared in this way from acetic acid, and at times illegally labelled "malt vinegar." At one time the so-called distilled or *white* vinegar was prepared by distilling the malt vinegar. It is difficult to see what advantages were gained by doing this, as the vinegar so prepared is indistinguishable from diluted acetic acid. A small quantity of sulphuric acid used to be regularly added to the vinegar, with the idea that it helped to preserve it. Such an addition is now illegal, and must be looked for in analysing a sample.

Pepper. Two varieties of pepper are commonly met with—*black* and *white* pepper. Both are obtained from a climbing plant, the *piper nigrum*, often trained like hops or vines to grow on poles. As soon as the berries show signs of turning red they are picked off and dried. *Black pepper* consists of this dried unripe fruit, in the form of rounded berries about one-fifth of an inch in diameter. The outer covering is then blackish-brown and wrinkled, and contains a seed of a yellow-brown or grey colour. This seed, from which the outer coating has been stripped, forms *white pepper*. For this stripping the fruit is soaked in water, in order to soften the husk or outer covering, which is then removed by rubbing. These outer husks possess some of the characteristics of the seed, and are used to a certain extent for flavouring. It will be seen, therefore, that the distinction between black and white pepper lies in the fact that the former consists of the seed contained in its husk or outer covering, while the latter is hulled and contains only the kernel. The peculiar pungency characteristic of pepper is due to the presence of an acrid resinous substance, besides which it contains small quantities of an oily body termed *piperin*, starch, and cellulose or woody fibre. The following table represents the average proportions of certain substances in black and white pepper (Clifford Richardson):

Substances	Black	White
	Per cent.	Per cent.
Water	8 to 11	8 to 11
Ash	2·75 to 5	1 to 2
Volatile oil	·1 to 1·75	·5 to 1·75
Piperin and resin	7 to 8	7 to 8
Starch	32 to 38	40 to 44
Fibre	8 to 11	4·11 to 8
Albuminoids	7 to 12	8 to 10

The manufacture consists in grinding the corns and separating the ground particles by means of

sieves. It is found that most of the active constituents are contained in the finely divided particles, the coarser particles containing mineral impurites and forming an inferior product.

Much ingenuity has been expended by unscrupulous dealers in incorporating with the pepper substances which are not easily discovered by the analyst. Besides the coarser mineral adulterants, such as china clay and starch, substances such as ground olive-stones and *long pepper* may also be added.

Cayenne Pepper. *Cayenne* pepper is obtained from the dried ripe fruit of the *Capsicum fastigiatum* and *Capsicum annum*, which grow in the tropical parts of Africa and America. The pods are orange-red in colour, perhaps ½ in. or so in length, having a shrivelled appearance. Inside are small white, rounded seeds. It owes its peculiar properties to a body known as capsicum, which is colourless, and has a very acrid taste. In addition to this, cayenne pepper consists of fibres and small quantities of fats and resin, but it is noteworthy that it contains no starch. For analysis the chemist must rely mostly on its microscopical appearance.

Mustard. There are two plants which furnish us with the raw material for the manufacture of mustard—namely, the *black* and *white* mustard plants (*Sinapis nigra* and *alba*), yielding respectively black and white mustard seeds. Both plants are found growing wild in most parts of Europe, the white mustard rather more in the south. The seeds differ a great deal in appearance. The white are about one-twelfth of an inch in diameter, and of a palish yellow colour, while the black seeds are considerably smaller, only about one-fifth of the weight of the white ones, and reddish to dark brown in colour. It is only the black mustard seeds which produce the peculiar volatile oil with the penetrating, pungent odour known as *allyl isothiocyanate*, so irritating to the nose and eyes. It is formed when the seeds are macerated with water. It is, however, a curious fact that the addition of white mustard increases the yield of the volatile oil.

To prepare mustard powder, a mixture of the two seeds is crushed between rollers and ground up. The product is then passed through sieves, and an impure mustard flour obtained. This flour is then subjected to a second sifting operation, and the product is ready for the market.

The allyl isothiocyanate exists in mustard in combination as glucoside (*Potassium myronate*), which is split up in the presence of moisture by a ferment, *myrosin*, also found in the seeds. White mustard contains myrosin, and therefore aids the formation of allyl isothiocyanate, although it does not itself contain any of the glucoside. If you wish to prepare some of this volatile oil, you merely require to macerate the black seeds with water, and, after standing for a time, distil, when the oil will pass over with the steam.

In addition to this volatile oil, mustard seeds contain some 35 per cent. of a fixed oil or fat, which is practically odourless and tasteless. There are also present albuminoids, from 25 per cent. to 30 per cent., cellulose, and about 1 per cent. of sulphur. Mustard, however, contains no starch, so that this possible adulterant is easily detected.

Adulterants of Mustard. In addition to starch, other adulterants which have been detected from time to time are turmeric, cayenne pepper, buckwheat, flour, clay, gypsum, and other mineral matters. Some mustard is poor in oil, being prepared from "mustard cake," the residue left after pressing the oil from the ground seeds.

Ginger. Ginger is the dried root, or, more correctly, *rhizome*, of the ginger plant (*Zingiber*), which is a native of India, but has been introduced into a number of other countries, such as Jamaica, Africa, and Japan. The best qualities come from Jamaica. It is prepared by scraping off the outer skin, washing and drying in the sun, and forms rounded, elongated pieces, branching off from one another. The usual colour is a pale buff, but sometimes the outer skin is not removed. "Coated ginger," or the scraped root, is whitewashed with chalk or chloride of lime to preserve it from the attacks of insects. The peculiar odour of ginger is due to a volatile oil, amounting to about ¼ per cent. of the weight of the root. The pungent taste is due to another constituent. In general, the composition of ginger varies a good deal; it contains resins, starch, fibre, and mineral matters.

Fraudulent practice in dealing with ginger is mostly confined to the sale of the "exhausted" product—that is to say, ginger which has been ground up and the essential constituents removed by digesting with weak spirit for making essences, etc. This form of adulteration is difficult to detect, as the appearance of the ginger is not altered.

Spices. Among the spices, *caraway seeds* are the dried fruit of the *Carum carui*, and contain about 5 per cent. of a volatile oil. *Cloves* are the dried calyx and flower buds of the *Eugenia caryophyllata*, a sort of myrtle which grows in Zanzibar and the West Indies. As in other spices, they owe their peculiar flavouring properties to a volatile oil, of which they contain up to 16 per cent. Allspice or *pimento* is the small dried berry of another variety of myrtle, the *Pimenta officinalis*. It contains about 4 per cent. of an oil similar to oil of cloves. Being cheaper, it is sometimes used to adulterate the latter. *Mace* is the outer coat or *arillus* of the *nutmeg*, the fruit of the nutmeg tree, *Myristica fragrans*. Nutmeg contains 6 per cent. of a pungent volatile oil, and mace about 4½ per cent. of a volatile oil. *Cardamoms* are the dried ripe seeds of several plants, and include the so-called "grains of Paradise." They contain the usual volatile oil and resin. *Cinnamon* is the bark of several allied trees, the best of which comes from Ceylon. The bark is stripped off in spring and autumn. It contains up to 1 per cent. of an essential oil, to which it owes its flavouring properties. It is sometimes adulterated with *cassia*, the bark of trees of the same genus, but of inferior value. Cassia is easily distinguished from true cinnamon, the latter consisting of thin curled pieces from which the outer and inner coats of the bark have been removed, while cassia forms thick pieces consisting of the entire bark.

Adulteration of Spices. Spices are very frequently adulterated, sometimes by the substitution of an inferior article, such as pimento for cloves or cassia for cinnamon, and also by the addition of various other waste materials, such as sand, gypsum, walnut and coconut shells ground up, ground olive-stones, mustard husks, and pepper refuse. These adulterants are readily mixed in with the ground spice; it is therefore much better to buy the whole spice and grind it as required for use. But even then certain adulterations may be effected.

Physical and Chemical Properties of Crude Petroleum.
Systems of Drilling Wells. Transport and Storage.

OIL PRODUCTION AND TRANSPORT

Physical Properties of Crude Petroleum. The unusual character of petroleum was the subject of much speculative comment by early writers on philosophical subjects. Thus, Francis Bacon, in 1627, described "the original concretion of bitumen" as a mixture of fiery and watery substance, and stated that "flame attracts the bitumen of Babylon afar off." Numerous references to the inflammable nature of petroleum were also made by the ancient historians. In his Life of Alexander, Plutarch describes how, in the district of Ecbatana (Kerkuk), Alexander was particularly struck with "a gulf of fire which streamed continuously, as from an inexhaustible source. He admired also a flood of naphtha not far from the gulf, which flowed in such abundance that it formed a lake. The naphtha in many respects resembles the bitumen, but it is much more inflammable. Before any fire reaches it, it catches light from a flame at some distance, and often kindles all the intermediate air. The barbarians, in order to show the king its force and the subtilty of its nature, scattered some drops of it in the street which led to his lodgings, and, standing at one end, they applied their torches to some of the first drops, for it was night. The flame communicated itself quicker than thought, and the street was instantaneously all on fire. . . ."

Hatchett, writing in 1798, divided bituminous substances into naphtha, petroleum, mineral tar, mineral pitch, asphaltum, jet, pit coal, bituminous wood, turf, and peat, and stated that when *naphtha*, the light, thin, often colourless oil, lost its lighter parts by exposure to the air, it yielded *petroleum*, which on further exposure gave *mountain* or *mineral tar*. Continued exposure, he added, produced *mountain* or *mineral pitch*, which in cold weather became brittle, but was soft and somewhat tenacious when warm, and by further induration *asphaltum* was produced.

Crude petroleum varies greatly in appearance, some descriptions being of pale colour and highly mobile, while others are viscid and almost black. The prevailing *colour* of the more fluid kinds of crude petroleum is chestnut-brown when viewed so that the light passes through the oil, but when the light is reflected from the surface of the oil the colour appears to be olive-green. An important indication of the character of a crude petroleum is afforded by its *specific gravity*, which is the ratio of the weight of a given bulk to that of an equal volume of water at 60° F.

Specific Gravity. The specific gravity of crude petroleum ranges from a little under 0·775 to a little over 1·0; therefore the lightest crude petroleum is about three-fourths the weight of water, and the heaviest about the same weight as water; but as it is exceptional to find crude petroleum approximating in specific gravity to the higher limit, the general experience is that it freely floats on water. When the area of a sheet of water on to which petroleum is flowing is sufficiently large in relation to the quantity of oil, the petroleum immediately spreads out into an exceedingly thin film which, on account of its tenuity, is iridescent, or, in other words, exhibits the colours of the rainbow, just as a soap-bubble does. This characteristic film has often led to the discovery of a valuable source of petroleum. Most descriptions of crude petroleum employed as a source of the usual commercial products have specific gravities between 0·8 and 0·9, but even within these narrower limits the specific gravity is a valuable guide to the nature of the oil. As a rule, the lighter the oil, the larger the proportion of kerosene or burning oil obtainable from it; and if the specific gravity exceeds 0·9, the petroleum will usually be found best suited for use as a fuel, or, in some instances, for the manufacture of lubricating oils. The *flash-point* of the oil, or the temperature at which it gives off inflammable vapour when tested in a prescribed manner (to be hereafter described), also affords an indication of the character of the oil. Most crude oils freely evolve inflammable vapour at ordinary temperatures; but if the oil requires to be heated considerably in order to cause the rapid evolution of vapour, it may be safely assumed that it is of little value as a source of kerosene; still less of the more volatile petroleum spirit used in motor vehicles. The *odour* of the oil is also a feature to be noted, for petroleum containing the objectionable impurity sulphur usually has an offensive odour, the normal odour of petroleum of high quality being not unpleasant. The temperature at which crude petroleum, which is quite fluid when warm, becomes solid on cooling affords an indication of the proportion of solid constituents present, which can be separated in the process of refining as paraffin wax, for candle-making. Thus, the crude petroleum of Burma, which yields a large percentage of this valuable commercial product, is solid at common temperatures, but becomes quite fluid on being warmed.

Chemical Properties of Crude Petroleum. To Hatchett, who has been already referred to, belongs the credit of having been among the first to form a clear conception of the chemical composition of petroleum, for he stated quite correctly, as early as 1798, that "the elementary principles of bitumen are carbon, hydrogen, sometimes azote (nitrogen), and probably some oxygen." The *carbon* appears to range between 79·5 and 88·7 per cent., and the *hydrogen* between 9·6 and 14·8 per cent. The proportion of *nitrogen* rarely approaches 1 per cent., and is usually very much lower than this. *Oxygen* also occurs only in small quantities, usually in the form of an acid. Some oils contain as much as 2 or 3 per cent. of sulphur, an impurity which frequently necessitates the adoption of a special refining process for its elimination. The carbon and hydrogen, of which all descriptions of crude petroleum are principally composed, occur in the form of liquid or solid chemical compounds termed *hydrocarbons*. Of these compounds, a large number have been isolated for examination, and it has been found that they constitute well-defined groups. Thus, the crude petroleum of the United States consists chiefly of a regular series of the compounds known as *paraffins*, each containing twice as many atoms of hydrogen as of carbon, and

two atoms of hydrogen in addition, while that of Russia consists principally of the compounds termed *naphthenes*, in which there are twice as many atoms of hydrogen as of carbon. Thus, among the hydrocarbons separated from American petroleum we have at one end of the series C_5H_{12}, C_6H_{14}, C_7H_{16}, etc., and at the other end $C_{25}H_{52}$, $C_{27}H_{56}$, $C_{30}H_{62}$; while the hydrocarbons separated from Russian petroleum include C_6H_{12}, C_7H_{14}, C_8H_{16}, etc., up to $C_{15}H_{30}$. These hydrocarbons exhibit regular progression in the *boiling-point*, those with least carbon being the most readily volatilised, and those with most carbon having the highest boiling-points. This character enables the petroleum refiner to classify the hydrocarbons present by the process known as fractional distillation, so as to obtain the desired commercial products.

The Production of Crude Petroleum. The operation of obtaining petroleum by the drilling of wells, which is technically termed "production," has been systematically conducted only during the past half-century; but the collection of the oil by the primitive process of skimming it from the surface of stagnant water, or bailing it from shallow excavations, was practised for ages previously, the oil being used as a lubricant for cart-axles, as a preservative of woodwork, especially of boats, and to a smaller extent as a medicinal agent. Before the drilling of wells was begun, there was an intermediate stage, during which petroleum wells were dug in the same fashion as a water-well, and were commonly lined with wood. In some countries, and notably in Burma and Rumania, the sinking of such wells was carried out with great ability and success, remarkable depths being reached, notwithstanding the difficulty and danger of the work, arising from the presence of suffocating vapour.

The Earliest Uses of Petroleum. The earliest detailed description of the collection of petroleum is that given by Herodotus, who describes operations which were carried on at the pits of Kir ab-ur Susiana (Kirab, 57 miles north-west of Shuster, in Persia).

Marco Polo, writing at the end of the thirteenth century, says of the petroleum of Baku, on the Caspian Sea: "On the confines towards Georgine there is a fountain from which oil springs in great abundance, inasmuch as a hundred shiploads might be taken from it at one time. This oil is not good to use with food, but is good to burn, and is also used to anoint camels that have the mange. People come from vast distances to fetch it, for in all the countries round there is no other oil."

Petroleum in England. There are many historical references to the occurrence of petroleum in England. An interesting case of the sudden influx of petroleum into a water-well at Ashwick Court, near Shepton Mallet, in Somersetshire, in the year 1892, was investigated at the time by the late Mr. Topley and the author. The well in question, which was the sole source of the water supply of the house, yielded, for some hours after the occurrence of an earthquake shock, a considerable quantity—stated to amount to several barrels—of petroleum. Petroleum has also recently been found in drilling for coal at Kelham, near Newark. On the other hand, several reported discoveries of petroleum have undoubtedly been explicable on the assumption that the oil had leaked from neighbouring petroleum stores. In the United Kingdom small quantities of petroleum have been obtained in North Staffordshire and Yorkshire, and during 1905 there was a production of forty-six tons in Dumbartonshire.

Modern Drilling Plant. The modern appliances most largely used consist of a percussion drill, driven by steam power, by means of which the rock is broken up and mixed with water to the consistency of mud, the detritus being removed from the borehole from time to time by the use of a long iron cylinder having a valve at the lower end. To a comparatively small extent a system of percussion drilling is also employed in which a stream of water under high pressure is driven through hollow drilling-rods, and issues from orifices in the cutting instrument or bit, the detritus being thus continuously washed out of the borehole. A rotary drill, with a circular cutting edge, has been employed for many years in the oilfields of Texas and Louisiana.

Cable System. There are several forms of percussion drill, chiefly differing in details, but there are only two to which it is necessary to direct special attention, as it is with these that the greater part of the work of drilling for petroleum has been, and is being, done. These are the American or cable system, in which the drilling tools are suspended by a manila cable, and the Canadian or rod system, with the modification used in Russia, in which the tools are attached to a string of jointed rods of wood or iron. The general appliances are substantially similar in these two systems, and it will therefore suffice to give a detailed description of the American or cable tools and machinery.

Oil-well Rig. The illustration shows a simple form of the standard rig employed in American oilfields. The derrick is a strong timber structure, usually at least 70 ft. in height, and 20 ft. square at the base, resting on wooden sills, and fixed by means of keys, so that it may readily be taken down and set up on a new site. To the band-wheel, which is fixed on the foundations a short distance from the derrick, motion is communicated by means of a belt from a horizontal steam engine of 30 to 35 horse-power, fitted with reversing gear. While drilling is in progress, this band-wheel imparts motion to the walking-beam, one end of which is immediately above it, through the medium of the crank and the wooden connecting-rod, or *pitman*, the length of stroke being adjustable, as shown in the illustration. At the opposite side of the derrick is a strong windlass, termed the *bull-wheel*, which is driven from the band-wheel, when required to be used, by means of an endless rope. The bull-wheel is provided with a powerful brake. A smaller windlass, called the *sand-pump reel*, is placed so that it can be driven off the band-wheel by a friction-pulley, actuated by a lever pivoted to the derrick floor. The throttle-valve of the engine is opened or closed by means of an endless cord passing into the derrick, the motive power being thus under the control of the driller. The drilling tools are attached to an untarred manila cable, 2 in. in diameter, which is coiled round the bull-wheel shaft and passes thence over a pulley at the top of the derrick, but when drilling is in progress they are suspended from the end of the walking-beam over the mouth of the well, and thus have the necessary vertical motion imparted to them.

The string of drilling tools consists of two parts separated by the jars, the lower one giving the downward blow, and the upper imparting an upward stroke, which serves to loosen the bit if it has become jammed in the rock. The lower portion consists of the bit, the auger-stem, and the lower half of the jars, while the upper portion

PETROLEUM RIG USED IN AMERICAN OILFIELDS

consists of the upper half of the jars, the sinker-bar, and the rope-socket with temper-screw. The bit is a steel-faced, chisel-shaped implement, about 4 in. in thickness, and of a width corresponding with the desired diameter of the borehole. The auger-stem is a solid rod, about 4 in. in thickness, and about 32 ft. in length. The jars may be described as resembling two long, flattened links of a chain. The sinker-bar is another solid rod about 12 ft. in length. The rope-socket is an arrangement for grasping the cable, and the temper-screw is a device for gradually lowering the string of tools as the drilling progresses. The various component parts of the string of tools are connected by male and female screws, the collars being squared for the application of wrenches.

Drilling the Well. In beginning a well, an ordinary shaft about 8 ft. or 10 ft. square is dug to a depth of 10 ft. or 15 ft., and a strong iron pipe furnished with a sharp steel shoe is driven down to a depth of 200 ft. or 300 ft., or until hard rock is encountered. The drilling tools suspended to the walking-beam are then set to work, and the rock is broken up by the successive blows of the bit. From time to time the walking-beam is disconnected, the bull-wheel set in motion, the tools drawn up into the derrick, and the detritus removed from the borehole by means of the sand-pump. This is a long iron cylinder, with a valve at the lower end, opening inwards. It is suspended from a cord passing over a small pulley at the top of the derrick to the sand-pump reel. On being lowered to the bottom of the well, the valve opens, and the cylinder fills with the detritus, which has been brought to the consistency of mud by means of water poured into the well as the drilling proceeds. On being raised by bringing the friction-pulley into contact with the band-wheel, the valve closes, and the contents of the cylinder are removed. While the tools are in the derrick opportunity is taken to sharpen the bit if it has become blunted.

Casing the Well. In some formations the drilling cannot be carried far without lining the well with iron casing to support the walls; and when a water-bearing stratum is perforated it is the practice to exclude the water by making a seating for this casing on a lower-lying impervious stratum, and continuing the drilling with a smaller bit and with the use of casing of less diameter, each string of casing extending to the surface. Apart from the necessity which may thus arise for reducing the diameter, it is usually found that when a considerable depth has been reached the casing becomes so firmly held by the walls of the well that it cannot be forced down any farther, and a smaller string has then to be inserted, with the result that wells of a depth of, say, 2000 ft., or from 2000 ft. to 3000 ft., may contain, when completed, many strings of casing.

Canadian System. The original Canadian or *rod* system differs from the system already described in the following particulars:

1. The substitution of wooden boring-rods for the cable. [See page 4386.]
2. The use of an auger in place of the spudding-bit in beginning the well.
3. The adoption of a somewhat different arrangement for transmitting motion.
4. The employment of a lighter set of drilling tools.

Russian System. In Russia (Baku oil-fields) the wells are of large diameter (often as much as 36 in., or even more, at the top) in order to reduce the risk of choking through masses of rock being driven into the bottom of the borehole by gas pressure, and to admit of the use of bailers of large size in raising the oil, the presence of sand preventing the employment of ordinary pumps. The drilling of wells of this large diameter is a comparatively slow and costly operation, necessitating the adoption of heavy tools and strong appliances generally. The system of drilling may be described as a modification of the Canadian system, in which iron rods are substituted for the wooden rods. Owing to their large diameter, the Russian wells are chiefly lined with riveted iron-plate casing instead of with the screwed artesian casing used in America.

Galician System. When the Canadian system was introduced into Galicia, it was found that considerable increase in the size and weight of the tools was rendered necessary by the greater hardness of some of the strata and the depth of the wells, but in principle the system remained substantially the same until recently. Now, however, it has become customary to employ a combination of the rod or pole system with the cable system, owing chiefly to further increase in the depth of the wells, which renders the time lost in disconnecting and reconnecting the screw-jointed poles a serious drawback, but in making this change a wire rope has been adopted in place of the manila cable used in America. In addition to the ordinary drilling tools, an expanding reamer is largely used in Galicia. This device is provided with two pivoted wings or dogs, forced outwards by powerful springs, and by means of it the size of the borehole can be increased at the bottom so as to admit of the casing descending quite freely.

Fishing Tools. In addition to the drilling tools employed in the various percussion drilling systems, a large number of "fishing" tools, many of which are of ingenious construction, are needed to deal with various mishaps which occur. A fracture of the drilling tools or cable or rods is not infrequent, or some portion of the string of tools may become detached, and in the absence of suitable appliances the well might have to be abandoned. By means of the fishing tools the broken end of the cable or rod can be grasped, or a hole drilled in a fractured tool lying at the bottom of the borehole, and tapped to receive a screw so as to admit of its being raised

Rotary System. The rotary system of drilling, already alluded to as being in use on the costal plain of Texas and elsewhere, is based upon that of Fauvelle, which was invented in 1842. It is admittedly one of the most rapid and economical systems which can be adopted in formations to which it is suited, but where very hard rock is encountered it is almost useless. It consists essentially in the employment of hollow drilling-rods or casing terminating in a drilling-bit or annular cutter, through which a continuous stream of water is pumped under a pressure ranging from 40 lb. to 100 lb. per square inch. The derrick is similar to that which has been described, but it is provided with a revolving table and gearing for rotating it by steam power, by means of which the rotation of the casing and bit is effected. The drilling tools are supported by a cable which passes from a swivel attached to them through a block and fall, and over a pulley at the top of the derrick to the hoisting drum. A flexible hose-connection is made from the swivel to the water-pumps, of which there are two, in order to ensure a continuous supply of water. The bits commonly employed

are the fish-tail, the core-barrel, and the adamantine or shot drill. The fish-tail bit is used for drilling in soft strata, such as sand and clay; the core-barrel bit in harder material, such as very compact clay, indurated sand, etc. In hard rock these two bits are ineffective, the progress made with them being very slow—in some cases only a few inches per day. Under these conditions the adamantine or shot drill is used, the abrasion of the rock being effected by steel shot, which are caused to revolve by the action of the bit. The detritus is carried continuously to the surface by the current of water passing downwards through the hollow rods or casing, and ascending in the annular space outside, and there is thus no need for the periodical clearing out of the borehole by means of a sand-pump, as in the ordinary percussion drilling system. If a porous stratum is met with, the water is liable to percolate into the rock; and to prevent this the water which is being pumped in is mixed with fine clay or mud, the porous bed being thus cemented up. The rotary system of drilling has been greatly improved within the past few years, and is now largely employed in the principal oilfields, either alone or, where hard strata are met with, in combination with the percussion system.

A TYPICAL GUSHER, WHICH YIELDS SOME THREE HUNDRED THOUSAND GALLONS OF OIL A DAY

Depth and Cost of Wells. In Pennsylvania the wells range in depth from 300 ft. to 3700 ft. Those of average depth cost about $3000, but the deeper ones may cost as much as

$7000. In Indiana the depth of the wells ranges from 900 ft. to 1650 ft., and the cost from $1200 to $1500. The average cost of the Texas wells is about $2000. The deepest well in the United States is said to be one drilled for water in Connecticut, which reached a depth of 6004 ft., with a diameter of 6 in. The second deepest was one in Pennsylvania, with a depth of 5575 ft. Many of the wells in the Boryslaw-Tustanowice district of Galicia are of a depth exceeding 5000 ft., and one has yielded oil from strata which have been reached at 5873 ft., or nearly a mile and a furlong.

Torpedoing Wells. In some of the oil-fields of the United States it is customary to explode a charge of nitro-glycerine at the bottom of the well in order to fracture the adjacent rock and thus facilitate the inflow of oil, as much as 100 or even sometimes 200 quarts of the explosive being employed in the deeper wells. The nitro-glycerine is carefully lowered into the well in a series of tin canisters, from 3½ in. to 5 in. in diameter and 10 ft. in length, the charge being exploded by a "go-devil squib" holding about a quart of nitro-glycerine and furnished with a percussion or time fuse.

Flowing Wells. In some localities a large proportion of the wells flow on completion, and not infrequently the stream of oil gushes from the borehole with almost uncontrollable violence, creating a spouter or fountain which may rise in the air to a height of 200 ft. or 300 ft. This is notably the case in the Baku oilfields, where the pressure exerted by the oil is said to have occasionally amounted to as much as 300 lb. per square inch. If the well spouts to a great height, the oil-spray is liable to be carried by the wind to a considerable distance, and ignition may occur at some boiler-fire, with the result of communicating flame to the well. A block of cast iron, about 4 ft. square and 6 in. to 8 in. in thickness is therefore placed in the derrick at a height of about 25 ft. above the mouth of the well, and the oil playing against this is confined to the immediate neighbourhood of the well. As soon as possible the oil is led into an excavation in the ground near the derrick; but although such a reservoir holds from 4000 tons to 6000 tons, it is quickly filled with oil and sand if the fountain is a strong one, and the derrick may even be buried in a sandhill in a short time. In such cases great loss of oil is unavoidable. The life of a fountain is very uncertain. The violent outbursts often lasts only for a few days or weeks, but the fountain may continue to play for more than a year. When the Baku wells do not flow, the oil is raised by means of bailers, which are long cylinders, similar to the sand-pump already described, with a valve at the bottom, for ordinary pumps cannot be used, owing to the large quantity of sand contained in the oil. Compressed air is also to some extent used to force the oil to the surface. From the earthen reservoirs the oil is pumped into cylindrical steel storage tanks after the sand has settled out of it, and is thence conveyed by pipe-lines to the refineries.

Yield of Wells in the United States. Although in some of the oilfields of the United States flowing wells yielding very largely are obtained, the average initial daily production of the whole of the productive oil-wells drilled in 1903 in the Appalachian oilfield (embracing the producing region in New York, Pennsylvania, West Virginia, Kentucky, Tennessee, and the south-eastern portion of Ohio) was 11·8 barrels per well. The term "initial daily production" signifies the quantity that any new well will produce during the first day after it has been completed.

Transport of Crude Petroleum. In the days of King Theebaw the produce of the wells in Upper Burma was carried in earthenware vessels. For many years subsequently the oil was brought down the river in bulk-barges, termed flats, by the Irrawadi Flotilla Company, but it is now transported from the oilfields to Rangoon by means of a pipe-line constructed by the Burma Oil Company. In Russia, until 1875, the crude oil was carried in barrels on Persian carts, known as "arbas," with huge wheels, 8½ ft. to 9 ft. in diameter, one barrel being placed in the body of the vehicle, and a second slung beneath the axle. In the United States the oil was at first transported in oak barrels, but after a short time bulk-barges, and an early form of tank railway-car with two wooden tub-like tanks, were empolyed. In 1871 railway cars with the present form of horizontal cylindrical iron or steel tanks were introduced.

Pipe Lines. The first successful pipe-line in the United States was laid in 1865, but it was not until 1875 that the construction of the great trunk lines was rendered necessary by the transference of the refining industry from the neighbourhood of the wells to the Atlantic seaboard and the shores of the Great Lakes. In 1892 the aggregate length of the trunk lines (chiefly 6 in. and 8 in. in diameter) was nearly 3000 miles, several of the individual lines being from 200 to 400 miles in length. In addition, there was a network of feeder-lines of smaller size, bringing the total length of piping up to about 25,000 miles. Since that date the number of lines and their capacity have been very largely increased. The trunk pipe-lines are made up in 18-ft. lengths of specially made lap-welded iron or steel pipe, tested to 2000 lb. per square inch, connected by long-sleeved screwed couplings, and are usually laid two or three feet below the surface of the ground, with bends at intervals to provide for contraction and expansion. The oil is forced through the lines by specially constructed pumps, which keep the column of oil in constant motion at a uniform rate of about three miles an hour; and in order to keep the lines clear of sediment a rotary scraper with radial arms, known as a *go-devil*, is from time to time forced through with the oil. The lines are worked in sections, with a pumping station for each portion.

Storage of Crude Petroleum. At convenient centres storage installations are erected. The tanks employed for this purpose in the United States are vertical cylindrical iron or steel tanks 90 ft. in diameter and 30 ft. in height, holding about 35,000 barrels. The tanks have slightly conical roofs covered with sheet iron.

Natural Gas. In the account already given of the geological and geographical distribution of petroleum a brief allusion was made to the gas so largely obtained in some portions of the Appalachian oilfields. The gas-wells are similar to the oil-wells; indeed, a well drilled for oil occasionally produces gas, and gas-wells after a time yield oil. The pressure under which the gas is met with may be as much as 800 to 900 lb. per square inch, and some wells have yielded about 30,000,000 cubic ft. daily. The gas is conveyed from the wells to distributing stations in pipe-lines like those used for oil.

Ozokerite. This is one of the solid forms of petroleum, and is mined in Galicia by means of shafts and galleries, similarly to coal, but exceptionally heavy timbering and efficient ventilation are needed. BOVERTON REDWOOD

Logarithms. Formulæ Connecting the Sides and Angles of a Triangle. Four Cases of Solution of Triangles.

SIDES & ANGLES OF A TRIANGLE

LOGARITHMS—continued

31. The decimal part of a logarithm is called the *mantissa*: the integral part is called the *characteristic*.

The logarithms of two numbers which have the same digits in the same order (i.e., they differ only in the position of the decimal point) have the same mantissa.

For example, let the numbers be 147·2 and ·01472. Then

$$147\cdot2 = \cdot01472 \times 10^4.$$
$$\therefore \log 147\cdot2 = \log \cdot01472 + 4 \log 10$$
$$= \log \cdot01472 + 4.$$

Hence, by keeping the mantissa always positive, the logarithms of numbers expressed by the same digits will only differ in the characteristic. Now, the characteristic of the logarithm of a given number can always be obtained by inspection. From Article **30** it is evident that

(i.) The characteristic of the logarithm of a number greater than 1 is *one less* than the number of *integral* figures in the number. Thus, characteristic of log 549·287 is 2, since there are *three* figures in the integral part, 549, of the number.

(ii.) The characteristic of the logarithm of a number less than 1 is negative, and is *one more* than the number of noughts between the decimal point and the first significant figure. The characteristic of log ·000582 is -4.

In order to denote that only the characteristic is negative, and the mantissa positive, the negative sign is written *over* the characteristic, and not *before* it. Thus, if the logarithm of a number is $-2+$ ·8257143, it is written $\bar{2}$·8257143.

Since the characteristic is found by inspection, the mantissa only is printed in the book of logarithms. For example, opposite the number 59082 we find 7714552. This means that 7714552 is the decimal part of the logarithm of any number which consists of the digits 59082 in that order. Thus, log 5908·2 = 3·7714552; or log ·059082 = $\bar{2}$·7714552.

32. Books of logarithms vary in detail, but all of them contain instructions for using their contents. In *Chambers' Mathematical Tables*, mentioned on page 5663, the use of the tables is explained by many worked examples, which the student will find no difficulty in understanding. The only thing we need refer to here is the *Rule of Proportional Differences*. The tables give the logarithms of numbers from 1 to 100,000, *i.e.*, number of five figures. The above rule enables us to find, by means of the tables, the logarithms of numbers having six or seven figures.

The rule is that *when the differences between three numbers are small compared with the numbers these differences are proportional to the corresponding differences between the logarithms of the numbers.*

Example. Find log 33651·4, having given that log 33651 = 4·5269980 and log 33652 = 4·5270109.

Let log 33651·4 = 4·5269980 + d.

Then, we have three numbers: 33651, 33651·4, 33652. The differences between the first and second and between the first and third are ·4 and 1. Again, we have three logarithms corresponding to the numbers, viz.:

4·5269980, 4·5269980 + d, 4·5270109.

The corresponding differences are d and ·0000129, and they are in proportion, so that

$$\frac{d}{\cdot0000129} = \frac{\cdot4}{1},$$

whence d = ·0000052 (to seven places).

$$\therefore \log 33651\cdot4 = 4\cdot5269980 + \cdot0000052$$
$$= 4\cdot5270032.$$

33. The logarithms of the ratios of all angles from 0° to 90° have also been tabulated. Sines and cosines are less than 1, and so also are tangents of angles between 0° and 45°. The logarithms of these ratios will therefore have *negative* characteristics.

To avoid printing these negatives, the number 10 is added to each logarithm. The result is called the *tabular* logarithm of the sine, cosine, etc., and is indicated by the letter L. Thus, in the tables we find L tan 35° 4′ = 9·8463018, so that log tan 35° 4′ = 9·8463018 − 10 = $\bar{1}$·8463018.

The rule of proportional differences is applied in the same way as in the case of numbers, so that from the logarithms of tan 35° 14′ and tan 35° 15′ we can find log tan 35° 14′ 25″, say.

Sides and Angles of a Triangle

34. In a triangle ABC, the letters A, B, C are used to denote the number of degrees in the angles at the points A, B, C respectively; so that "sin A" means "sine of the angle at A." The letters a, b, c, denote the lengths of the sides BC, CA, AB, *i.e.*, the sides opposite respectively to the points A, B, C.

35. *To prove that* $\cos A = \dfrac{b^2 + c^2 - a^2}{2bc}$.

Since a Δ has at least two acute angles, one of the angles B, C, must be acute. Let B be acute. Draw CD $\perp$ to BA or BA produced. In the three cases, where A is acute, obtuse, or a right angle, we have

(1) $BC^2 = CA^2 + AB^2 - 2\,BA\,.\,DA$ (*Prop.* 69);
or, $a^2 = b^2 + c^2 - 2c\,.\,DA$.

But $\frac{DA}{AC} = \cos A$, so that $DA = b \cos A$.

$\therefore a^2 = b^2 + c^2 - 2bc \cos A$.

(2) $BC^2 = CA^2 + AB^2 + 2BA\,.\,AD$ (*Prop.* 70);
or, $a^2 = b^2 + c^2 + 2bc \cos DAC$.

But $\cos DAC = \cos(180° - A) = -\cos A$.

$\therefore a^2 = b^2 + c^2 - 2bc \cos A$.

(3) $BC^2 = CA^2 + AB^2$.

$\therefore a^2 = b^2 + c^2 - 2bc \cos A$,
since $\cos A = \cos 90° = 0$.

Hence, in all three cases we have

$$\cos A = \frac{b^2 + c^2 - a^2}{2bc}.$$

Similarly,

$$\cos B = \frac{c^2 + a^2 - b^2}{2ca}, \quad \cos C = \frac{a^2 + b^2 - c^2}{2ab}.$$

36. Let $a + b + c = 2s$.
Then $b + c - a = b + c + a - 2a = 2s - 2a = 2(s - a)$.
Similarly, $c + a - b = 2(s - b)$,
and $a + b - c = 2(s - c)$.

37. *To prove that*

$$\sin \frac{A}{2} = \sqrt{\frac{(s-b)(s-c)}{bc}},$$

and

$$\cos \frac{A}{2} = \sqrt{\frac{s(s-a)}{bc}}.$$

We have $2 \sin^2 \frac{A}{2} = 1 - \cos A$ [Art. 26]

$$= 1 - \frac{b^2 + c^2 - a^2}{2bc} = \frac{2bc - b^2 - c^2 + a^2}{2bc}$$

$$= \frac{a^2 - (b^2 + c^2 - 2bc)}{2bc} = \frac{a^2 - (b-c)^2}{2bc}$$

$$= \frac{(a + b - c)(a - b + c)}{2bc} = \frac{2(s-c)\,.\,2(s-b)}{2bc}.$$

$\therefore \sin \frac{A}{2} = \sqrt{\frac{(s-b)(s-c)}{bc}}$.

Also,

$$2 \cos^2 \frac{A}{2} = 1 + \cos A = 1 + \frac{b^2 + c^2 - a^2}{2bc}$$

$$= \frac{2bc + b^2 + c^2 - a^2}{2bc} = \frac{(b+c)^2 - a^2}{2bc}$$

$$= \frac{(b + c + a)(b + c - a)}{2bc} = \frac{2s\,.\,2(s-a)}{2bc}.$$

$$\therefore \cos \frac{A}{2} = \sqrt{\frac{s(s-a)}{bc}}.$$

Similarly,

$$\sin \frac{B}{2} = \sqrt{\frac{(s-c)(s-a)}{ca}}, \quad \cos \frac{B}{2} = \sqrt{\frac{s(s-b)}{ca}},$$

$$\sin \frac{C}{2} = \sqrt{\frac{(s-a)(s-b)}{ab}}, \quad \cos \frac{C}{2} = \sqrt{\frac{s(s-c)}{ab}}.$$

38. From the last article we have

$$\tan \frac{A}{2} = \frac{\sin \frac{A}{2}}{\cos \frac{A}{2}} = \frac{\sqrt{(s-b)(s-c)}}{\sqrt{s(s-a)}}.$$

Similarly for $\tan \frac{B}{2}$ and $\tan \frac{C}{2}$.

39. Since $\sin A = 2 \sin \frac{A}{2}\,.\,\cos \frac{A}{2}$ [Art. 26].

$$\therefore \sin A = 2 \cdot \sqrt{\frac{(s-b)(s-c)}{bc}} \cdot \sqrt{\frac{s(s-a)}{bc}}$$

$$= \frac{2}{bc} \cdot \sqrt{s(s-a)(s-b)(s-c)}.$$

The expression $\sqrt{s(s-a)(s-b)(s-c)}$ is usually denoted by S. Hence, $\frac{\sin A}{a} = \frac{2S}{abc}$. In the same way we get $\frac{\sin B}{b} = \frac{2S}{abc} = \frac{\sin C}{c}$.

Therefore, in any triangle

$$\frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}.$$

40. *To prove that* $\tan \frac{B-C}{2} = \frac{b-c}{b+c} \cdot \cot \frac{A}{2}$.

Since $\frac{\sin B}{b} = \frac{\sin C}{c}$. $\quad \therefore \frac{b}{c} = \frac{\sin B}{\sin C}$.

$\therefore \frac{b-c}{b+c} = \frac{\sin B - \sin C}{\sin B + \sin C}$ [Algebra, Art. 139]

$$= \frac{2 \sin \frac{B-C}{2} \cdot \cos \frac{B+C}{2}}{2 \sin \frac{B+C}{2} \cdot \cos \frac{B-C}{2}} = \frac{\tan \frac{B-C}{2}}{\tan \frac{B+C}{2}}.$$

But $\frac{A + B + C}{2} = 90°$.

$$\therefore \tan \frac{B+C}{2} = \tan\left(90° - \frac{A}{2}\right) = \cot \frac{A}{2}$$

$$\therefore \frac{b-c}{b+c} = \frac{\tan \frac{B-C}{2}}{\cot \frac{A}{2}};$$

or, $$\tan \frac{B-C}{2} = \frac{b-c}{b+c} \cdot \cot \frac{A}{2}.$$

Similar formulæ can be proved for $\tan \frac{C-A}{2}$, and $\tan \frac{A-B}{2}$.

41. By the aid of the formulæ in Articles **35** to **40** we can solve a triangle when we are given three of its parts, one of the given parts being a side. These formulæ are therefore very important.

Solution of Triangles

42. There are four cases.
(1) Given the three sides.
(2) Given one side and two angles.
(3) Given two sides and the included angle.
(4) Given two sides and the angle opposite one of them.

43. Given the three sides a, b, c.
From any of the formulæ of Articles **37** and **38**, we can calculate two angles, say A and B. The third angle is $180° - A - B$.

For logarithmic computation these formulæ are adapted as follows:

$$\tan \frac{A}{2} = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}}.$$

$\therefore \log \tan \frac{A}{2} = \mathrm{L} \tan \frac{A}{2} - 10$

$$= \log \sqrt{\frac{(s-b)(s-c)}{s(s-a)}} = \log \left\{\frac{(s-b)(s-c)}{s(s-a)}\right\}^{\frac{1}{2}}$$

$$= \tfrac{1}{2}\{\log(s-b) + \log(s-c) - \log s - \log(s-a)\}.$$

H. J. ALLPORT

The World Trade of the British Isles at the Eve of the Great War

BRITAIN IN BUSINESS

BRITAIN in business with the world is a deeply interesting study. In the BUSINESS group we give a broad sketch of the national economy [see pages 735 and 865], and show how the position of the United Kingdom, as a great and populous country, depends upon the maintenance of export power—power, that is, to secure, by oversea trade, wealth which Nature denies to the British Isles. We now proceed to examine these all-important conditions in concrete.

Our Dependence on Foreign Commerce. The facts we are about to examine are supremely important to every man of business, no matter what his particular line of activity may be. Our dependence upon foreign commerce is so great that foreign products are necessarily built into every part of the framework of our lives. We are clothed almost entirely in foreign fibres; we are housed in buildings in which foreign materials play a conspicuous part; our instruments of work and pleasure are largely fashioned out of woods and metals and other substances earned by us in dealings with persons oversea. The food and fodder consumed by ourselves and our flocks and herds and domestic animals are, as to about one half, sea-borne.

It matters not that a man may be immersed in what appear to be entirely domestic or home operations. In essence he is as fully dependent upon export trade as though he were directly an export manufacturer or export merchant. Whether he be physician, painter, writer, actor, banker, stockbroker, policeman, carpenter, or what not, he lives and works in a great community which is built upon foreign commerce, and which, without foreign commerce, would shrink to the dimensions of a tenth-rate nation living at a much poorer standard of existence than now obtains. It is therefore a matter of the liveliest interest to every man and woman in the country how we trade, where we trade, and why we trade. It is the duty of every intelligent Briton to get a good working conception of one of the most remarkable things in the world—the British national economy. The latest official analysis of British commerce *before the War* is for the year 1913, and we give above a very simple statement of the main facts.

A BIRD'S-EYE VIEW OF BRITISH COMMERCE IN 1913

(The figures represent millions of £.)

CLASS OF TRADE	A Gross Imports	B Imports re-exported	C Imports for consumption (A—B)	D Exports of British goods
Food, drink, tobacco	290	16	274	33
Raw materials ..	282	64	218	70
Manufactures ..	194	29	165	411
Miscellaneous ..	3	1	2	11
Totals for 1913 ..	769	110	659	525
Corresponding Totals for 1912	745	111	634	487

NOTE.—The corresponding totals for 1912 are given for comparison. It will be seen that the trade of 1912 made a considerable advance upon that of 1912. As to the progress of commerce in the past, see the table in BUSINESS, Chapter 7, on page 866.

British Commerce Examined. The statement exhibits the enormous aggregate of British oversea trade as classified in three great divisions: The first, food, drink, and tobacco; the second, raw materials; and the third, manufactured articles, leaving over a small quantity of miscellaneous goods.

The nature of the vertical columns should be very carefully noted. Column A, Gross Imports, shows the total value of the goods imported, and as valued at British ports, including the cost of freight and of insurance from their ports of origin, or c.i.f. (cost, plus insurance, plus freight), as the commercial world terms it. The larger part of these imports is consumed in the United Kingdom, but a part is re-exported, in the same form as imported, by merchants. This re-export, or entrepôt trade, as it is sometimes called, is shown in column B. By deducting column B from column A, we get column C, which thus represents the imports into the United Kingdom for home consumption as distinguished from the gross imports of column A.

We then come, in column D, to the exports of British goods. These consist of British products and manufactures, the manufactures, of course, often being made up of imported materials. Exports, it should be noted, are valued at what is known as "free on board" (f.o.b.) values. They represent the value of the goods as placed on ship at British ports, and they do not include the freight and insurance of the goods to their ultimate destinations in foreign countries and British possessions.

With these necessary explanations, the meaning of the table can be properly appreciated. We see that in 1913 the gross imports of the United Kingdom were £769,000,000, and that £110,000,000 worth of these imports were re-exported, leaving £659,000,000 worth for home consumption. As to exports of British goods, we see that the value of goods shipped from British ports in 1913 amounted to £525,000,000, a record figure for this or any other country.

Imports and Exports Compared. The striking dissimilarity of our import and export trade is clearly brought out by the broad analysis.

As to food, drink, and tobacco, we see that our imports for home consumption were about

eight times as great as our exports—namely, imports, £274,000,000; exports, £33,000,000.

As to raw materials, we see that our imports for home consumption were about three times as great as our exports—namely, imports, £218,000,000; exports, £70,000,000. It should be observed that of the £70,000,000 worth of British exports of raw materials as much as £54,000,000 consisted of coal, leaving only £16,000,000 worth of British exports of raw materials proper in 1913. Thus, apart from coal, our imports of raw materials for home consumption are normally about fourteen times as great as our exports.

As to manufactured articles, we see that exports very largely exceed imports, being as nearly as possible two and a half times as great as imports—namely, exports, £411,000,000, and imports, £165,000,000. Broadly, then, it is true to say that British imports chiefly consist of foods and raw materials, while British exports chiefly consist of manufactured articles.

Turning to the totals for 1913, we see that imports for home consumption were worth £659,000,000, while exports of British goods were worth £525,000,000. It is not only the greatest, it is also the most remarkable, commerce in the world. No other great nation has such a peculiar dependence upon imports. It should never be forgotten that both our exports of British goods and the British goods which we make for our own home market are equally fashioned, in great degree, from imported materials.

In the important table we have reviewed, the great categories into which it is divided—categories which came into use upon the suggestion of the present writer in 1902—are necessarily of a somewhat arbitrary character. It is very difficult to draw the line between a raw material and a manufactured article, and in practice what is the finished manufactured article of one trade is often the raw material of another trade. The category "Food" necessarily includes both crude food products, such as corn or chilled beef, while it also includes manufactured foods, such as sugar and tinned lobster among the imports, and jam and biscuits among the exports. On this head it may be remarked that a very large part of the British exports of food consists of manufactured articles.

As to the big category "Manufactures," the imports and the exports are concerned with large quantities of articles which are partly manufactured, and with finished articles which are bought for use as materials. As to partly manufactured articles, we may note such things as crude copper, iron, zinc, tin, lead, etc., of some of which we import enormous quantities. As to wholly manufactured articles used as materials, we may note such things as leather, paper, and the like, which also figure largely among our imports.

Imports of Raw Materials. Of the gross imports into the United Kingdom in 1913, which, as we have seen, were worth £769,000,000, imports of manufactures amounted to £194,000,000; and among these imports of manufactures may be noted the following huge items representing, not goods brought in ready for the ultimate consumer, but as raw materials of industry.

SOME IMPORTS OF MANUFACTURES CHIEFLY CONSISTING OF MATERIALS OF INDUSTRY

	£
Miscellaneous metals	32,100,000
Chemicals, etc.	12,900,000
Leather, etc.	13,400,000
Paper	7,700,000
Woollen and worsted yarns	3,500,000

The Sources of British Imports. It is next of the deepest interest to see how this mighty oversea trade is divided as between foreign countries and British Possessions. In this analysis we may deal with the figures of 1912, which clearly show the nature of the case.

First, as to the origin of imports. This is clearly and simply shown in the following statement, using the same classifications as before.

UNITED KINGDOM GROSS IMPORTS (1912) FROM FOREIGN COUNTRIES AND BRITISH POSSESSIONS RESPECTIVELY

(In Millions of £.)

Class	From Foreign Countries	From British Possessions	Total
Food, drink, tobacco	200	80	280
Raw materials	193	83	276
Manufactures	164	22	186
Miscellaneous	2	1	3
Total	559	186	745*

* Of this £745,000,000, £111,000,000 was re-exported, leaving £634,000,000 of imports for home consumption in 1912.

We see by this that of the gross imports, amounting to £745,000,000 in 1912, as much as £559,000,000, or 75 per cent., came from foreign countries. From them we draw the greater part of the food and indispensable raw materials which we earn by our commerce. Nevertheless, British Possessions are great and increasing suppliers, and in 1912 we derived from various parts of the British Empire £163,000,000 worth of food and materials. As to manufactures, we see that the greater part of the imports come from foreign countries, British Possessions being as yet not greatly developed as export manufacturers.

Where Britain Sends Her Exports. In the next statement we make a similar analysis of the destinations of the exports of British goods in the year 1912.

UNITED KINGDOM EXPORTS OF BRITISH GOODS (1912) TO FOREIGN COUNTRIES AND BRITISH POSSESSIONS RESPECTIVELY

(In Millions of £.)

Class	To Foreign Countries	To British Possessions	Total
Food, drink, tobacco	20	13	33
Raw materials	15	2	17
Coal	41	1	42
Manufactures	228	157	385
Miscellaneous	6	4	10
Totals	310	177	487

The fine total of £487,000,000 was so divided that approximately two-thirds of our exports went to foreign countries, and one-third to British Possessions. Our coal exports went, of course, chiefly to foreign countries, for our Oversea Dominions are at a considerable remove from our shores, and they can hardly, therefore, import coal from us. As to manufactured articles, foreign coutries are our best customers, but British Possessions are increasingly important ones, and in 1912 it will be seen our exports of this kind to British Possessions amounted to as much as £157,000,000 worth, as compared with £228,000,000 worth sent to foreign countries.

A Grasp of Our Commercial Position Essential. It is, of course, a much easier thing to set out these gigantic totals than to grasp their true significance. We speak of the nation as trading with the various countries of the world, but what really takes place is that individuals in the United Kingdom trade with other individuals in places abroad. It is a thing of extraordinary complexity, this commerce of ours, and it involves operations sometimes lucid and sometimes exceedingly obscure. In some cases a manufacturer directly exports to a foreign or Colonial customer, seeking orders by direct representation, so that he is not only manufacturer but export merchant. In other cases, such direct exportation is unknown or rare in a trade, the export manufacturer relying upon export merchants to secure his orders. Thus it may easily happen that a British manufacturer doing a great export trade has no direct communication with the people who buy his goods, and he may, therefore, remain in complete ignorance of the methods of export trade, and of the machinery by which international transactions are settled. As for the public at large, they see in the shops the foods of oversea origin, and the goods so largely made out of foreign materials, but rarely do they have any opportunity of gaining insight into the real source of the commodities they purchase, or of the materials which compose them. The complexity of modern commerce has been so great, indeed, that goods are not only bought by people who do not understand them, but sold by storekeepers who, in many cases, could not give you an intelligent account of how they came into existence.

There is an element of danger in this position, for the currents of commerce are even more easily changed in modern times than in the old days which saw the rise and fall of many great nations. The study of British commerce should therefore be widely pursued, that the nation should not, amid a mass of complexities and in a fog of obscure detail, lose sight of the vital points upon which the continuance of such a great trade, and the consequent continuance of Britain as a great nation, absolutely depend. For a study of this part of the subject, BUSINESS [page 865] should be carefully consulted.

Food Imports Vital to Us. It will help to a conception of the magnitude of our imports if we remember that, large as our population is, it numbers no more than nine million families. As our imports for home consumption in 1912 amounted to £634,000,000, we see that we imported in that year £70 *worth of foods, materials, and manufactures for each family in the country!*

Our conception of the volume and variety of our imports is further assisted by looking at the matter in more detail. Here is a statement of the quantities of the chief foods imported in the year 1912.

QUANTITIES OF THE CHIEF FOODS IMPORTED: 1912

Wheat	109,600,000	cwt.
Flour	10,200,000	„
Maize	43,900,000	„
Barley	20,100,000	„
Oats	18,300,000	„
Beef	8,600,000	„
Mutton	5,100,000	„
Bacon	4,600,000	„
Butter	4,900,000	„
Cheese	2,300,000	„
Eggs	2,300,000	thousands
Apples	3,900,000	cwt.
Bananas	7,000,000	bunches
Oranges	5,600,000	cwt.
Lard and imitation lard	2,000,000	„
Margarine	1,300,000	„
Cocoa (raw)	75,300,000	lb.
Tea	361,100,000	„
Sugar and molasses	98,200,000	cwt.
Potatoes	5,800,000	„
Onions	9,400,000	bushels
Tomatoes	1,400,000	cwt.

There is a host of other foods imported, but we have dealt with the main items only. This great importation is supplemented by a home production, as to which it may be broadly stated that, taking all kinds of foods together, such as we can produce in our climate, we produce about one-half of what we consume.

Our imports of tobacco amounted to 141 million lb. in 1912, and our imports of wine to 12,200,000 gallons. Of brandy we import 1,400,000 gallons, of rum 4,000,000 gallons, and of gin 1,000,000 gallons, but the chief alcoholic spirit consumed in this country—whisky—is, of course, mainly produced at home.

Imports of Raw Materials. The list of the chief raw materials imported is equally impressive.

CHIEF RAW MATERIALS IMPORTED IN 1912

Iron ore	6,700,000 tons.
Other ores (value)	£9,100,000
Wood	9,700,000 loads.
Cotton	28,000,000 centals (of 100 lb.)
Wool	857,400,000 lb.
Woollen rags	114,600,000 lb.
Miscellaneous textile materials (value)	£18,600,000
Petroleum	413,100,000 gallons
Oils, oil seeds, various (total value)	£37,400,000.
Hides and skins (value)	£13,700,000.
Sheepskin	78,000,000 lb.
Wood pulp and other paper materials	1,200,000 tons
Rubber	1,100,000 cwt.

Here are the chief materials upon which British work is done, with power produced from our all-important coal. In 1912 we imported 2800 million lb. of raw cotton, or over 60 lb. for every man, woman, and child in the country, although the greater part of the cotton goods

made from it are exported. As to raw wool and woollen rags, we imported over 20 lb. per head of population. Of timber, a load was imported for every family in this country, and the importation of 413 million gallons of petroleum in various forms is another extraordinary item.

As to metals other than iron, we import them chiefly extracted from their ores, so they do not appear in the above list. In 1912, it may be remarked, we imported over £31,000,000 worth of miscellaneous metals, chiefly in an unmanufactured form, and without these our brass and other metal industries could not continue.

As will have been gathered from the broad anaylsis of our imports already given, we lay all the world under tribute for the wealth which enriches us, and which we have seen to be largely foreign to these islands.

The Wheatfields that Feed Us. From period to period, as the world develops, the sources of our imports undergo change and modification. A striking illustration of this fact is to be found in regard to corn. Not many years ago we derived the greater part of our wheat supplies from one country, the United States. In 1912, although the United States was still a considerable supplier, she supplied only about one-fifth of our wheat. Here is a comparison of 1902 and 1912, which will show that remarkable changes have taken place in the sources of our imported wheat.

WHEAT IMPORTED INTO THE UNITED KINGDOM
(FLOUR INCLUDED IN EQUIVALENT WEIGHT OF GRAIN)

SOURCE	1902	1912
	Cwt.	Cwt.
From Foreign Countries :		
U.S.A.	65,000,000	25,800,000
Argentina	4,500,000	18,900,000
Russia	6,600,000	9,000,000
Other countries	6,400,000	4,400,000
	82,500,000	58,100,000
From British Possessions :		
Canada	12,200,000	27,100,000
Australia	4,200,000	12,900,000
India	8,800,000	25,400,000
Other British Possessions	200,000	200,000
	25,400,000	65,600,000
Total : All the world ..	107,900,000	123,700,000

In 1902 the United States furnished 65 million cwt. out of a total of 107,900,000 cwt. of wheat imported by us. In 1912 our imports had risen to 123,700,000 cwt., but the United States supply had fallen to 25,800,000 cwt. Fortunately, other countries, especially Argentina, Canada, Australia, and India, redressed the balance, but the falling off in the United States supply has meant a rise in the price of corn.

This table may be taken as a typical example of the need in our day to keep a constant and watchful outlook upon world developments. There is an accelerating swiftness of movement in commercial developments. It is now possible for a country to build up a new trade in ten years to considerable dimensions, and almost to lose it in another ten years. Even to be pioneers in a trade counts for little in the twentieth century. For example, the French were pioneers in the motor-car industry, and for some time held the lead, but they have now fallen behind in an industry which they can claim to have invented. Those who are not prepared to march swiftly with the times after the Great War will find themselves beggared by new competitors.

The statement we have just given with regard to corn, taken together with the analysis of imports generally, goes to show that British Possessions are gaining upon foreign countries as suppliers of our imports. Indeed, the movement in this connection has been very rapid.

Cotton. With regard to our supplies of materials, our dependence for raw cotton upon the United States is still a remarkable thing. In 1912 we imported 28 million centals (100 lb.) of cotton. Over 27 million centals came from foreign countries, and of these 55,200,000 centals came from the United States, Egypt supplying 20,800,000 centals. Of late years a little has been done by the British Government to assist systematic development of cotton-growing within the British Empire, but much more needs to be done. There is very great danger in the cotton position so long as the present circumstances remain. The development of American cotton manufacturing under a saner fiscal system, and with the assistance of the Panama Canal and the remarkable changes which it will make in trade routes, is likely to proceed apace. It is possible, therefore, in the course of another ten or fifteen years, that America will be absorbing all the cotton that she produces. In short, we may expect to occur in American cotton what has already occurred in American wheat. Should that prove to be the case, the position of Lancashire will be deplorable if, in the meanwhile, cotton-growing within the British Empire has not reached considerably greater dimensions. We may have here another instance of swift modern development inimical to our commercial interests.

As to timber, we have an obvious duty to perform, and that is to raise as much as possible upon those millions of acres in the British Isles which are quite suitable for the purpose, for timber is now steadily growing dearer.

The Empire must Look Ahead. The time has come when it should be our business to remember that the British Empire is a great trust, which it is our duty to administer in conservation of its wealth, and for the mutual benefit of its various parts. When we consider Britain in business with the world, this side of the subject assumes a great and growing importance. The time is surely coming when the world as a whole will have to have a stern regard to its limited resources; and in view of the fact that the British Empire forms so considerable a proportion of the world we have a special and grave responsibility. THE DIVER PHOTOGRAPHED IN MID-AIR

AN EXAMPLE OF THE HIGH SPEED ACTION OF THE MODERN KODAK CAMERA

FACING PAGE 5933

Cameras, Lenses, and Plates. Intensifying and Reducing. Enlarging. Lantern Slides. Carbon Printing. Flashlight Work. Press Photography.

DARK-ROOM PHOTOGRAPHY

Plate Cameras. Cameras for use with dry-plates may be roughly divided into three classes, according to whether they are for use in the hand or on a tripod; these three classes are hand, hand or stand, and stand. In the hand cameras the subject to be photographed is seen only in the finder (except in the *reflex cameras*, where a full-size image is projected by means of a mirror on a screen in the top of the camera). In the hand or stand cameras there is a finder, for use when hand exposures are made, and a focussing screen at the back, where the image is seen exactly the size it will appear in the finished picture, but upside down. In the stand cameras, however, there is no finder or focussing scale; the image is seen only on the focussing screen.

Sometimes the user of a plate camera wishes to have the advantage of the lightness of films. He then buys a Premo Film Pack Adapter, at a cost of a few shillings, which takes the place of his ordinary dark-slide. Into this adapter he places the Premo Film Pack, which holds a dozen flat films, and which can be loaded and unloaded in daylight.

Generally speaking, the photographer should buy the highest-priced camera he can afford. Although this advice is given, it must not be thought that the more expensive the camera the better the photograph that can be taken with it. Very much more depends on the photographer than on the camera. It is quite possible to take as good a photograph with a five-shilling camera as with a five-guinea one. But the limitations of usefulness are narrower on the cheaper camera, and it will, of course, not be so well constructed, and will therefore not last so long. The cost of a camera depends chiefly on the lens with which it is fitted.

The Choice of a Lens. The lenses fitted to cameras are of three kinds, single, rapid rectilinear, and anastigmat. The single lens is usually fitted to the cheaper types of cameras; sometimes it is listed as a *meniscus achromatic*. Single lenses have to be worked at a small aperature, or else they do not give a sharp image. Working at a small aperture, they do not pass very much light, and consequently are slow. They also show distortion in photographs where there are straight lines near the edges of the subject.

Rapid rectilinear lenses, frequently abbreviated to R.R. lenses, overcome the two chief failings of the single lens. They work at a larger aperture, and consequently are faster; they also overcome distortion. The chief failing of the rapid rectilinear lens is that the image is likely to "fall off" in sharpness near the corners of the negative unless it is worked at a small aperture. Medium-priced cameras are usually fitted with a rapid rectilinear lens.

The best lenses are the *anastigmats*. They do not have to be "stopped down" to a small aperture in order to get good definition, and they work at high speeds

Plates. Plates are made with varying degrees of sensitiveness. In the "Royal Standard" plates, for instance, there are the rapid, extra rapid, special extra rapid, and lightning. As a general rule, the amateur will find it better to work with the slower speeds at first; the very rapid plates had better be left until he is thoroughly proficient with the slower. Sometimes the beginner blames his plates when he is not getting satisfactory results, but almost invariably the fault is in his working, and not in his materials. One frequent cause of trouble is that the dark-room light is not really safe. There may be chinks through which daylight enters, or the lamp itself may pass rays of actinic light. This is shown by the negative being "veiled." The edges, or the "rebates," as they are called by photographers, should be perfectly clear; if they are not, it is a sign that the light of the dark-room is not safe. Then again, markings in negatives are frequently put down to faults in making the plate, whereas they arise from a fault which the photographer little suspects—that is, dirt. In the dark-room absolute cleanliness must always be observed. And directions should always be carefully followed. If a formula says that a certain substance has to be dissolved, it must be thoroughly dissolved; imperfectly dissolved substances account for a lot of the markings in negatives.

Developing formulæ are not given here, because every packet of plates gives the formula which the makers have worked out as the best for the plates contained in the packet.

Correct Colour Rendering. Certain plates, variously called chromatic, isochromatic, or orthochromatic, are more sensitive to green and yellow than ordinary plates. When a yellow screen is placed on the lens, the plate's excessive sensitiveness to blue it reduced, and so a negative is obtained in which white clouds are shown in their proper relation to blue sky. But if absolutely correct colour rendering is desired, it is much better to use such a plate as the Wratten "Panchromatic," which is not only sensitive to green and yellow but also to red. The best screens are those which are made by the makers of the Wratten Panchromatic plates, and sold under the name "K" filters.

After-treatment of Negatives. The head of an important photographic business once told his staff that there were no such things as intensifiers or reducers! He went on to explain that if their first negatives were not so good as they should be, they must take them again. If there was not time to take them again, they must choose a printing-paper which would give a good result from the poor negative. Many amateurs would be surprised if they know how little intensifiers and reducers are used by professional photographers. The great thing is to endeavour to get a correctly exposed and developed negative in the first place, and only to use intensification or reduction as a last resort. Another point is that negatives should always be thoroughly fixed and washed before treatment.

Intensifiers. What treatment is given depends on the fault to be remedied. If the negative is under-exposed, it will be shown by absence of detail in the shadows. The *uranium intensifier* should be used, made up as follows:

A. Uranium nitrate	100 grains
Water	10 ounces
B. Potassium ferricyanide	100 grains
Water	10 ounces

Take one ounce each of A and B, and add two drachms of acetic acid.

If the negative is under-developed, there will be detail in the shadows, but the whole image will be too thin. The *chromium intensifier* is then the best. Bleach in the following:

Potassium bichromate	5 grains
Hydrochloric acid (1.160)	1 minim
Water	1 ounce

Wash until the yellow stain is removed, and then develop (by daylight, or after exposure to daylight) with amidol.

Reducers. Sometimes a negative gives "soot and whitewash" prints, generally caused by over-developing a plate which has been slightly under-exposed. The ammonium persulphate reduces the density of the high-lights without attacking the detail in the shadows.

Ammonium persulphate	5 to 10 grams
Water	1 ounce

After reduction, the plate should be placed in a 5 per cent. solution of sodium sulphite for a few minutes, to stop the action of the reducer.

If the negative is dense all over, and takes a long time to print, Farmer's reducer should be used, but remember that it is poisonous. A 10 per cent. solution of potassium ferricyanide is added to hypo solution until it is pale yellow. The negative must be thoroughly soaked before placing in this solution. As soon as sufficiently reduced, the negative must be thoroughly washed.

Enlargements by Daylight. When we have made some successful small pictures, we are sure to become more ambitious, and anxious to make larger pictures. To do this it is not necessary to get a larger camera, but we can supplement our small camera with an enlarging camera. There are two kinds of cameras for enlarging, one for daylight and the other for artificial light. A daylight camera which will enlarge from quarter-plate size ($3\frac{1}{4}$ in. by $4\frac{1}{4}$ in.) to whole-plate ($6\frac{1}{2}$ in. by $8\frac{1}{2}$ in.) can be bought for a few shillings, so that the initial expense is not very great. We must, however, buy larger dishes for the larger size of paper. In the daylight enlarger of fixed focus, enlarging from quarter-plate to whole-plate, the light passes through the negative and then through a lens, so that the image is projected upon the printing-paper fixed at the other end.

Enlarging bromide paper is, as a rule, very sensitive to light, so that the packet should be opened and the enlarging camera loaded only in the dark-room. Those who have already mastered gaslight printing by contact will make successful enlargements at once, as the same kind of paper is used. The length of exposure depends on the strength of the light and the speed of the paper. Owing to the expense of waste, it is well to make test exposures in the camera with small pieces of paper before risking a whole sheet. The makers of paper now recognise this by enclosing an extra piece, quarter-plate size, which may be used for preliminary test.

Formula for amidol: amidol (or diamidophenol), 80 grains; sulphite of soda, 2 oz.; water, 12 oz.; bromide of potassium, 15 grains.

This has to be made up fresh for each printing, and deteriorates in about ten hours. The bromide of potassium makes the developer a little slower, but brightens the prints. A negative that may print rather thin and flat with P.O.P. may give bright prints in an enlargement if we under-expose and use a strong solution.

Artificial Light Enlarging. But by far the most satisfactory method of enlargement is by artificial light. Here our light is always of the same strength, whereas daylight is constantly changing. Another great advantage is that we can control the printing. For instance, we may have a negative of an interior lit up by a window or flashlight on one side. By placing a piece of cardboard in front of the thinner portions of the negative, we can to a large extent rectify this unevenness of lighting, and make a presentable print.

Another advantage about the artificial enlarging lantern is that it may be used as a magic-lantern, and we can amuse our friends by throwing our pictures on the screen.

The cost, however, of the artificial lantern enlarger is greater than the other, since a "condenser" or larger lens for concentrating the light has to be used. This in itself is so expensive that a reliable enlarger can hardly be bought new for less than three guineas. We can, however, often pick one up secondhand for rather less. The photographer who wishes to go in for Press or professional portrait work later on will find this artificial light enlarger absolutely necessary.

In the enlarger for use with artificial light the light, which is usually an incandescent or electric light, preferably the former, is behind the condenser, and the condenser concentrates the light on the negative. Through the negative the light passes on to the lens, and the image is thrown into focus on bromide paper, either fixed on a slide or pinned on a board fixed upright at the requisite distance. We require no elaborate stand for our enlarger, but can prop the spare leaf of our dining-room table against the wall of the dark-room and set the enlarger on two wooden chairs of equal height. An arrangement for focussing enables us to enlarge to any size or in any proportion we desire. If by any chance we have tilted our camera by mistake, and so got the lines in the wall of a house slanting, we can stop down the lens in the enlarging camera, and tilt the support of the paper slightly, so as to correct this awkward mistake. We can very often improve our negative by enlarging only the interesting portion of it. A sharp negative will enlarge many diameters without showing any trace of enlargement. Experienced tourists know this, and often prefer to take with them only a quarter-plate camera, knowing that they can enlarge their good negatives to any size at home.

Hints for Enlarging. The lens in the enlarging camera should always be stopped down a little, as this tends to give a brighter print. The utmost care should be taken to keep the hands perfectly clean in printing, otherwise the paper will show stains. It is always advisable to "clear" an enlarged print, as the paper, especially if of glossy surface, is inclined to show markings, due in no way to the operator. This clearing solution is the same as the reducing solution (ferricyanide of potassium) mentioned already. Dip a piece of cotton-wool in this, and gently rub the surface of the paper while still damp. This will clear the whites wonderfully, and will even remove slight yellow stains due to previous carelessness.

We can focus accurately on the paper by placing in front of the lens a yellow glass cap, which is removed for the exposure. These caps are stored by any dealer who has enlarging cameras. All

white light, however, should be excluded from the room, as the bromide paper used for enlarging is sensitive to the light, far more so than is generally supposed. If we want to be sure of good prints, we must run no risks. Do not expose the print after development to any other than the light shown through this yellow glass till the print has been at least five minutes in the hypo (fixing) solution, or we risk getting it fogged.

Lantern Slides. Lantern-slides are very easily made, without special apparatus, by contact printing. They are really positive prints made on glass instead of a paper support. We will probably find among our negatives a number in which a square of 3¼ in. makes a good picture. This is the size of the lantern-slide. The positive is made by contact in the same way as in the case of gaslight papers, but it is well to clear the slides for the sake of improved transparency after development and fixing, and before washing. Here is a well-known formula for *clearing solution:*

Protosulphate of iron, 3 oz.; alum, 1 oz.; citric acid, 1 oz.; water, 20 oz., or in proportion. The depth to which a lantern-slide should be developed can be gauged only by experience. If, however, we study a good lantern-slide, such as we often see in an optician's window, or such as are sold for educational purposes, we can save ourselves much trouble and waste.

If we wish to secure the whole of our negative on our lantern-slide we can still do so without special apparatus. We must block up the whole of a window lighting a room with dark brown paper, leaving only a hole the size of our negative. Into this hole the negative is fixed, say, by means of sticking-plaster over the corners. We must now photograph this negative on a prepared lantern-plate, focussing accurately and getting the image as near 3¼ in. at its widest part as possible. We should stop down our lens to at least F/22, and back our plates with backing-paper, which may be bought at 6d. a box. The lantern-slide plates will fit into the sheaths of our camera, but must, of course, be fixed in the middle of the sheath, otherwise the picture may overlap the plate.

The positive plate has to be mounted before it is a complete slide, otherwise the film would be quickly destroyed by the heat of the lantern. Cover-glasses, made of very thin glass, and of the same size (3¼ in. by 3¼ in.), are placed so as to cover the sensitive side of the positive, and the two glasses are bound together by binding strips round the edges. This binding is quite easy to do.

More Advanced Work. Although a great deal may be done with a quarter-plate combined with an enlarging camera, we may be pardoned if we grow still more ambitious. The average lens, even in expensive quarter-plate cameras, has so short a focus that distortion is difficult to avoid. By *focus* we mean the distance in the camera between the centre of the lens and the photographic plate. The human eye is said to have a lens corresponding to one of 16 in. focus, but the quarter-plate camera is satisfied with 4½ in. or 5 in. It is, of course, possible with a focussing camera to adapt a telephoto lens, such as the "Adon," to overcome this objection, but for many reasons we should do better still with a good half-plate camera. It is a good plan to get a camera with a double anastigmat lens, in which the front and back portions of the lens (each of different focuses) can be used separately or in combination, giving us the choice of using short or long focus lens at will. Thus, a combined lens which has a focus of 6½ in. may consist of a front portion with focus of 14 in., and a back portion with focus of 9 in. The camera that is to hold such a lens must, of course, have a bellows capable of extending to 14 in. In the case of portraits, the longer the focus the better. A curious fact also is that a large lens seems to give more modelling and to get round the objects more than a small lens of the same focal length.

Carbon printing and the subsidiary processes so much affected by artistic workers are hardly worth attempting in less than half-plate size. It is, of course, possible to make enlarged negatives and to print from these, but, after all, the best method of making enlarged negatives is by the carbon process.

Carbon Printing. The chief makes of carbon tissue—the Autotype Co. and Elliott & Sons—supply such elaborate directions that it is unnecessary here to give more than a brief outline of the process. A good plan is to experiment with the Trial Set supplied by the Autotype Co., or the Sample Set supplied by Elliott & Sons.

The principle and method of carbon printing are so simple and the results so artistic that we can well understand why it has taken the foremost place both in amateur and in professional photography. We may begin by explaining how the image is made in the carbon tissue. It has been discovered that gelatin combined with bichromate of potassium becomes more or less insoluble according to the amount of light to which it is exposed. When a prepared gelatin tissue is exposed to the light under a negative it becomes insoluble in depths which vary according to the strength of the light which the negative allows to pass through its parts. A small amount of light passes through the whole of the negative, and therefore the whole of the surface of the tissue is affected and becomes insoluble. The problem is, how are we to get to the lower layers of the tissue, so that we can dissolve away that which has not yet been affected by the light? This is done by transferring the tissue from the paper on which it is originally mounted to a new support, face downward. When this transfer is made, the soluble portions now exposed can be cleared off by the application of warm water, and the positive image—made of insoluble gelatin—brought to view.

The Single Transfer. In the single-transfer method of carbon printing—the simplest, and therefore the best to begin with—the image is reversed from left to right, but very often this does not matter. The sensitive tissue is usually made up twice a week by the companies that supply it, and should be used within nine days, as it does not keep. Prints should be made in dry weather only. The safe-edge mask—supplied in the Trial Set—must always be applied round the edges, otherwise the transfer is apt to be unsatisfactory. No image is seen at first in the printing, so that an actinometer for measuring exposures has to be used. A simple actinometer is supplied with the Trial Set. The time required for printing is considerably less than that for P.O.P., and the action of the light continues—at a reduced rate—after the tissue has been taken out of the frame. We may turn this continuing action to advantage in the case of prints which are suspected of under exposure. If these are kept for twenty-four hours before development they may turn out all right.

The single-transfer paper is slightly larger than the mounted carbon tissue. It is placed face upwards

THE SMILE

ON THE BEACH

A LITTLE GIRL AND HER FRIEND

These photographs are reproduced by courtesy of the Imperial Dry Plate Co.

in a tray of cold water at about 60° F., and all air bubbles must be carefully removed. We should have a depth of at least 1½ in. of water in the tray. Then the exposed tissue is placed face downwards in the water, and the fingers gently slid along the surface underneath tore move air bubbles. The tissue will flatten out, and then begin to turn up at the edges. The tissue and the transfer paper are now brought into contact under water and taken out together, and then squeegeed into perfect contact with a scraper squeegee such as is supplied with the Trial Set. The two sheets are now put between blotting-paper, and laid under a heavy weight, such as a large book. This secures uniform pressure. All the prints are treated thus, and left under pressure for about half an hour or till the back of the transfer paper has turned yellow.

Developing with Water. For development, two baking-tins, costing about a shilling each, will do. But we must not use these tins afterwards for baking, as bichromate of potassium is a strong poison, and the success of our printing should make us desire to live a little longer. Fill a tin with water heated to 90° F. to 100° F. The gelatin soon begins to ooze out at the edges. Then transfer the sheets to a tray of slightly hotter water, 100° F. to 110° F., about 1½ in. deep. Holding the combined sheets under water, lift up a corner of the tissue sheet and gently strip it off. If it does not strip off readily, leave it a little longer and try again. The gelatin is now transferred to the new support, and the lower soluble layers are exposed and can be treated. The transfer paper, to which the tissue now adheres, is placed on a slab or flat dish at an inclined angle, and laved with water at 100° F. to 110° F. by means of a teaspoon. Gradually the image will appear as the soluble part is washed away. We lave it till it is a little lighter than we desire the finished print to be. The water can be kept at an even temperature by placing the tray on a gas-stove with the gas-jet at the proper height. If the tissue has been over-exposed, it does not easily dissolve, and still hotter water must be used. This, however, must be used with care, as it is apt to cause blisters.

The great charm of carbon printing is that local development can be carried out easily. A sky that would otherwise be lost can be saved by developing the upper portion of the picture in cooler water than the lower, and over-exposed portions can be reduced by careful laving with hot water, or the local application of sulphocyanide of ammonia.

When the print has been sufficiently developed it must be cleared and hardened. A filtered 5 per cent. solution of powdered alum in water is the bath. This clears away the yellow stain and hardens the film, after which the prints should be washed for half an hour in running water, and then hung up with clips to dry.

Double Transfer and Modifications. In the double-transfer method, a temporary support is used instead of the single-transfer paper, and from this temporary support the image is transferred to a final support. This double transfer restores the image to its natural position. For making enlarged negatives, a special transparency tissue is made, which requires half more exposure than the ordinary kind. This is transferred by the single-transfer process to a glass support, and printed through an enlarging camera on to a negative of the size required. The image is reversed to its natural position by keeping the tissue side of the glass towards the source of light.

Modifications of the carbon process avoid transfer, but usually require us to sensitise our own solution. On the whole the old method is the most satisfactory of all printing processes, and we do not grudge the slight extra trouble.

The Press and the Editor. Photography for the Press contains more of the element of uncertainty than any other branch of the craft. If you are actually on the staff of a paper, this uncertainty is, of course, diminished, but between the free-lance and success a thousand chances intervene. Still, it is one of the most interesting, and often one of the most profitable, forms of using the camera. A very skilful and successful photographer for the Press acknowledges that, after paying all expenses, he clears about £500 a year. It must be remembered, however, that he is at the top of the tree, and has fifteen years of hard work behind him. The main point to remember is that we cater not so much for the public as for our editor. We must give him the kind of print and subject he wants, not what is intrinsically best. Very often we shall find our best work thrown on our hands, owing to his personal tastes, or the space he may have at his disposal. "Better luck next time," we must say— and try again.

In the first place, it is advisable to make our prints not less that half-plate size, and with a glossy surface, which may even be squeegeed. The reproduction the editor may make may be only 3 in. by 4 in., but he personally likes to see the prints large. For this reason, most Press photographers use a half-plate camera, so that they can readily run off contact prints, and in many cases they print through the enlarging camera on glossy bromide paper, submitting pictures whole-plate size. The glossy surface is not really necessary for reproduction, and some engravers actually damp their paper to get rid of the gloss before making their block, but few editors know this, and prefer the print which apparently shows most detail. There are, of course, exceptions, and "Country Life," for instance, takes artistic photographs even on rough surfaces. This extreme, however, is only possible in the case of a magazine with very fine printing.

Camera for Press Work. The most convenient all-round camera to use is a light, folding half-plate camera with a focal plane shutter giving exposures down to 1000th part of a second, and either slides or a magazine containing 12 plates. Our outfit will cost us about £20. The lens should be able to work well at F/6·3., or if possible F/5, and the finer the lens the more likely we are to achieve success under all conditions of weather. We must be prepared to make bright, contrasty pictures at seven in the morning on a rainy day. One of the most successful Press photographers uses a lens with 10 in. focus, but this requires more experience in accurate focussing than, say, a Goerz-Anschutz with lens of 7 in. focus. Some get over the difficulty by having both a long and a short focus lens. This, of course, requires a camera that can be adapted to different lenses. It must be remembered that, especially in sporting photography, we have to snap at a distance from the object required, and yet our figures must be as large as possible. We do not recommend the reflex type of camera for general work. Many of the most skilful Press photographers do not even use a finder, but gauge by experience the view taken by the angle of their lens, and point the camera breast-high at the person or object required. In snapshotting celebrities, this is often the only practical method. We have to keep our

eye glued to our victim, and at the same time have the whole field in view, otherwise we may miss the characteristic attitude, or someone will step in front at the critical moment. In a crowd we may even have to hold our camera above our head.

In addition to the snapshotting of news events there is also a vast field of magazine work. Skill in portraiture is also a great advantage, as the illustrated newspaper of today becomes more and more personal in its interests. One successful photographer has made a speciality of doing for the Press artistic portraits of celebrities at home or in their natural surroundings. The chief London photographers naturally acquire numbers of portraits which are in demand with editors. So much is this the case that they sometimes have to retain a special staff for running off prints for the Press.

Celebrities. So much are celebrities photographed nowadays that few copyrights are worth more than ten guineas at the outside. The usual fee for reproductions of photographs of any sort by an illustrated paper is 10s. 6d. per print for reproductions up to 6 in. by 4 in., and a guinea beyond that size. Reduction in price is frequently asked and granted for a series or set of photographs, but the half-guinea is a useful standard, fair alike to editors and photographers. Occasionally an editor will offer to buy exclusive rights in a photograph for a definite period, when we may get from one guinea to ten guineas. Such occasions and such editors are rare.

Advanced Flashlight. The Press photographer must be master of flashlight work, as the subjects required—especially in magazine work—have often to be taken under difficult lighting. A small room may be lit up sufficiently by magnesium powder or a flashlight candle, but it is advisable to know how to manipulate more powerful flashlights. There are several kinds of explosive powders used in advanced flashlight work, but the safest, and at the same time one of the most brilliant, is *argentorat*, which has the merit of not being set alight by percussion. It is so highly inflammable that it must be handled with great care, and must not be lighted with a match held in the hand. Also, it must not be used in a closed lamp, such as is used with magnesium powder, but in an open metal tray. A handy portable lamp for use with these special flashlight powders is the Weiss lamp, in which a match, close to the powder, is ignited by pulling a string. Another lamp ignites the powder by means of an electric spark.

So vivid is the light of a powder such as argentorat that people jump out of their seats, and they should therefore be cautioned in advance that there is no danger. The flash is so rapid that the photograph is taken before the movement occurs. The smoke is, unfortunately, a great nuisance, and our flashlight may occasionally bring up the fire brigade on a false alarm. Scrape the ash carefully off the tray after each flash, otherwise your later flashes will be accompanied by loud explosions.

Sale and Speed. Country photographers often find it convenient to sell prints through the Press photographic agencies. These send representatives round the chief editorial offices, charging 15 per cent. to 25 per cent. commission. In the case of news photographs, where there is no time to run off many prints, these agents are very handy, as one editor may have special reasons for refusing good prints, for which another has space. In the case of news pictures, speed is half the battle. Pictures of an event that happens on a Monday morning should be submitted, if possible, the same afternoon. Methylated spirits of good quality enable one to dry prints and negatives very rapidly.

Mr. F. C. Bowden, of Bowden Bros., perhaps the most skilful sporting photographer in this country, has kindly sent us the following hints for those who intend going in for such work.

1. Get your figures as large as possible. Avoid having a heavy background of trees when taking fast exposures. They look artistic in the finder, but don't reproduce well, owing to under-exposure.

2. Don't keep changing your brand of plates. Start with a good make, and use only the fastest for extreme exposures. It does not do to use the slower and cheaper make, as the results cannot be obtained with these.

3. When developing, avoid using too much ruby light. The less the better.

4. Don't be impatient with very fast exposures when developing. Anybody can press the button and take a picture in a 1000th part of a second, but it is not everybody who has the patience to develop a plate for an hour or two, as is often the case in winter.

5. A lens working at a large aperture, say F/5·6, is essential.

6. Don't press the shutter release on camera with a jerk.

7. Rehearse in your mind what you are going to do; and when the moment arrives, do it.

Professional Portraiture. The best guide to those who intend to take up professional portraiture is naturally one who has himself succeeded. Mr. E. C. Elliott, of the firm of Elliott & Fry, gives some practical advice on the subject. "Don't try at first to get into a big London house," he says. "Get into a good, moderate-sized provincial house where everything is done under one roof. At Elliott & Fry's, for instance, every department is specialised, and it would be difficult for one to get that general grasp of a business which is essential for a man who intends eventually to set up for himself. After one has realised what one is best fitted for, one may decide to specialise, for instance, as an operator or a printer, a retoucher, or finisher. If you decide to set up for yourself, you must be up to date, and a little before it. I don't know that it is advisable to start with a partner. Partnerships are very uncertain things, and I think that, at any rate to begin with, a clever man with a capable staff can manage by himself. Wherever you are, you must adapt yourself to your locality. A seaside or suburban photographer has quite a differente clientèle from that of Elliott & Fry, and yet may do excellent business. The things to remember are that, whatever your kind of photography may be, you should try to be good of your kind, and that you should not cut prices. You must be up to date in the getting up of your mounts, in printing methods, framing and displaying, while such small details as price-lists, packing of pictures, labels and notepaper should be studied, with a view to making them as attractive as possible. Every young professional photographer—in fact, every photographer, young or old—would do well to become a member of and support the Professional Photographers' Association, and so have at his disposal, in all matters of difficulty which may arise, the help and advice of a committee of the most experienced men in the profession."

WHAT MAN CAN MAKE OF THIS BARE EARTH

A CORNER OF THE LOVELY GARDEN AT "WIGGIE," REDHILL

THOUSANDS OF VISITORS TO REDHILL HAVE CALLED AT THE LOVELY GARDEN OF MR. ARTHUR TROWER, WHOSE GATE IS ALWAYS OPEN TO THOSE WHO LOVE NATURE

Roses, Lilies, Chrysanthemums, Carnations, and Sweet Peas. Bulbs. Tall, Dwarf, and Bedding Plants and Flowers. Ferns. Orchids. Glasshouses.

FAVOURITE GARDEN FLOWERS

A YOUNG gardener is sure to be called upon to pay special attention to the five favourite garden flowers: the rose, lily, chrysanthemum, carnation, and sweet pea.

The Culture of the Rose. The rose has often justly been called the "Queen of Flowers," and it is well to remember that her Majesty requires regal treatment. Failure with roses is generally due to the fact that they are planted in the wrong sort of soil. It is impossible to get good roses in bad ground, and, where the soil is not suitable for their cultivation, it must be taken away, and proper material introduced. The soil in which the rose thrives best is a good rich loam two or three feet in depth, resting on a subsoil of clay. The clay subsoil, being impermeable, retains all moisture, and so keeps the roots of the roses cool during the hot months of summer. Where the soil is very light it must be made heavier by the addition of thick, heavy loam and clay, otherwise the gardener is merely courting failure. Roses are generally grown in the forms of "Standards," "Dwarf Standards," "Bushes," or "Climbers."

A standard is a rose which has been grafted on to a stem about three feet in height. A dwarf standard has been grafted at about half that distance, while a bush usually springs from the ground without showing any main stem at all, having been grafted close to the roots. Roses on their own roots—that is to say, roses that have not been grafted at all—are invariably grown as bushes.

Roses are usually grown as standards when extra large-sized blooms are required for exhibition purposes, or where space is limited. In places where plenty of room is available there is no doubt that the easiest way to grow the rose is in its bush form, as it blooms far more freely under these conditions.

The Best Varieties of Roses. Roses are divided into several sections, or groups, the most important of which are: Teas, Hybrid Perpetuals, Noisettes, Hybrid Teas, Bourbons, Monthly roses, and Ayrshires, titles which are derived chiefly from the land of their birth, or the time of flowering. Altogether there are over two thousand varieties in cultivation, and the number is added to every year.

The following twenty-four sorts recommended by "The Century Book of Gardening" as suitable for town and suburban culture are, perhaps, as judicious a selection as could be made for all purposes:

Red: General Jacqueminot, Alfred Colomb, Abel Carrière, Dupuy Jamain, Cheshunt Hybrid (climber).

Pink: Mrs. John Laing, Baroness Rothschild, La France, Captain Christy, and Pink Rover (climber).

White: Boule de Neige, Merveille de Lyon, and Aimée Vibert (climber).

Yellow: Marie van Houtte, Madame Hoste, Emily Dupuy (climber), and Medea.

Apricot: Francisca Kruger, Safrano, Rêve d'Or (climber).

Salmon: G. Nabonnand, Bouquet d'Or (climber), Dr. Grill, and Felicité Perpetuel (climber).

For town gardens, however, the following sorts should on no account be omitted: Frau Karl Druschki (white), Caroline Testout (pink), Lady Waterlow (pink), Gloire de Dijon (yellow), William Allan Richardson (apricot).

How to Propagate Roses. The three chief methods of propagating roses are by grafting, budding, and cuttings. Grafting [19] and budding are usually performed upon the stem of a wild briar whose sturdy growth makes it eminently adapted for the purpose. This briar is called a stock, and the main stem is cut down to the desired height of the standard, or bush, as the case may be. A V-shaped notch is cut in the top of the stock, from one to three inches deep, according to its diameter. The end of the graft (the rose which it is desired to propagate) should be cut wedge-shaped in order to fit the notch in the stock, and carefully inserted, the junction being thickly covered with clay to afford protection. The operation of budding consists in lifting, with a very sharp knife, a bud, and about a quarter of an inch of the bark round it, and inserting it in a stock. The stock is prepared by cutting a T-shaped slash in its bark, raising the bark gently with the knife, so that the bud may be inserted underneath it, and, when once the bud is in position, binding it round fairly tightly at top and bottom, to ensure its retaining its position.

Cuttings are slips taken off with a slanting cut, and containing two or three "eyes." They are best potted up in small pots in a mixture of sand and leaf mould. If put in a frame and well exposed to the sun they will root in about a month, but must be kept free from frost all the winter, and gradually hardened off the following spring.

The operation of pruning roses is carried out in the spring, and is better performed with the secateur than the pruning knife. Climbing roses do not, of course, require so much pruning as the standard or bush sorts. Probably no two rose-trees require exactly the same sort of pruning, but the golden rule to be observed is to see that the branches in the centre are well thinned, so that light and air have free access.

The best time for planting roses is from November to March—the earlier the better. All newly-planted roses should have protection from frost during the winter months. This may be afforded by a mulch of straw, bracken, or similar material.

The Lily. Though not so popular as roses, perhaps, lilies of varied sorts must be found in profusion in every garden which pretends to be at all representative.

Generally speaking, lilies do not like a heavy soil; consequently, with the exception of a few varieties, the heavy clays which are to be found so frequently in the neighbourhood of large towns and cities are not calculated to grow them to the best advantage. A light rich soil, with plenty of sand and leaf-mould in it, is what the lily revels in, and it is one of the few flowers which has no liking for the presence of animal manure.

Lily bulbs should be planted at a depth of from six to eight inches, and their bases should rest upon a liberal dose of silver sand. The most popular forms of lilies suitable for culture in gardens are given in the table on the next page.

The Chrysanthemum. The immense popularity to which the chrysanthemum as an exhibition flower has attained during recent years

has militated somewhat against its general employment as a garden plant.

THE MOST POPULAR LILIES

Name.	Height.	Colour of flower.
Auratum ..	About 6 ft.	White with yellow band
Bulbiferum ..	2 ft. to 3 ft.	Orange red, black spots
Madonna ...	tall, varies	White
Easter	2 ft.	White
Tiger	3 ft.	Red, purple spots
Speciosum rubrum	2 ft. to 3 ft.	White, pink spots, crimson markings
Orange	6 ft.	Orange, black spots
Scarlet Martagon	3 ft.	Bright red
Elegans ..	1 ft. to 2 ft.	Orange

It is a perfectly hardy flower, and, if it is not intended for exhibition, may be grown in the garden border with the same facility as the dahlia. Chrysanthemums are apt, certainly, to be damaged by rains and frosts in the late autumn, but they may be protected from this by an awning of some light material, such as waterproof calico. If grown in pots, they are generally transported at the first sign of frost into a cold greenhouse, and left to finish blooming there. This is the method attendant with least risk, and is generally adopted.

Chrysanthemums are divided into three classes: Incurved, Japanese, and Pompon. The incurved variety, as its name implies, has all the petals curving inward, and overlapping, so that it somewhat resembles a flattened ball in shape. In the Japanese variety of chrysanthemum the petals throw themselves about in every direction, so that the flower looks like the head of a mop, earning for it the colloquial name of "ragged chrysanthemum." The Pompon is a dwarf with small, closely petalled flowers, rarely more than two inches in diameter.

Growing Chrysanthemums for Cutting and Exhibition. The best soil in which to grow chrysanthemums is equal parts of loam, leaf mould, sand, and rotten manure. The young plants should be put in about March or April, according to the weather, about three feet apart every way. If they are simply to be grown for the purpose of cutting, there is no need to tamper with them again, except to give them an occasional dose of liquid manure, but if they are destined for show or decorative purposes in pots it is usual to remove many of the buds so that the whole strength of the plant can be concentrated upon two or three blooms, which will necessarily be of gigantic size. Chrysanthemums grown for this purpose, however, are usually cultivated in pots, beginning with a small thumb pot, and repotting each time into a larger size, until they are finally placed in nine-inch pots, which should contain the best loam, with a little finely powdered charcoal. It is necessary to tie chrysanthemums grown for large blooms to sticks, otherwise they will be topheavy, and fall over.

Like so many other flowers which the nurseryman has taken in hand, the chrysanthemum has innumerable varieties. A few of the best for general culture are Soleil d'Octobre (golden yellow), Madame Desgrange (white), Montague (purple crimson), Ryecroft Glory (yellow-shaded bronze), Vivian Morel (pale pink), Madame E. Roger (green). The last-mentioned variety is somewhat of a freak, and would be grown more as a curiosity than for any ornamental value; it is, however, very hardy, as it does well in many parts of London.

The "Buttonhole" Flower. If the carnation were grown for no other purpose, it would always be sure of a prominent place in gardens by reason of its value as a "buttonhole" flower. To be seen at its best in the open garden, however, it should be grown in beds or clumps. A good plan is to grow the bold, self-coloured sorts in beds, and have little clumps here and there, dotted about the borders, of picotees, flakes, and bizarres. These last three terms are the names by which the striped and marked varieties of carnation are known.

Layering Carnations. A rich, loamy soil is necessary for the carnation. This soil must be well drained, and just a little sand mixed with it. The richer the soil the more vigorous the carnation, but on a light soil the plant will never do well. The chief methods of propagation are from seed, and by the operation known as *layering* [24]. Layering is carried out in July or August, when the plant is in full vigour. Select a good strong shoot near the base of the plant, and clean off all the leaves on that shoot with a sharp knife, except half a dozen at the top. Cut half way through the shoot from below in an almost horizontal direction, for a distance of about 2 in., taking care to cut through a joint in the stem on the way. Push the wounded part of the shoot into the soil, which has been previously prepared by having sand mixed with it, and keep it in that position by pegging it down. Special pegs may be procured for this purpose, but a common hairpin answers the purpose almost as well.

Carnation seed must be sown in May, in pots or boxes of rich loamy soil. They must be stood in a sheltered spot, and, when the plants show a few leaves, they can be put out in beds of the same material, and left till late autumn. If they have the protection of a frame during winter, many of the young plants will bloom the following season.

Among the best carnations for the open garden are: White: George Macquay, Trojan [20], Alice; Pink: Duchess of York, Asphodel, Endymion, Raby Castle, Enchantress; Yellow: Miss Audrey Campbell; Buff: Mrs. Reynolds Hole, Prince of Orange. Scarlet: The Cadi, Isinglass, King Arthur; and Crimson and Dark Red: the old Clove Carnation, Uriah Pike, Mephisto, Boadicea.

The picotee and other fancy varieties of carnation are more numerous even in variety than the good self colours. Six good ones are Cardinal Wolsey, Ladas, Perseus, Dervish, Mrs. Robert Sydenham, and the Czar.

The Sweet Pea. There is probably no more popular annual flower in the garden than the sweet pea, and certainly none which yields a more bountiful supply of bloom for cutting. It may be had in practically every colour from white to what may, by a very slight stretch of imagination, be called a black, and is of the easiest culture. The sweet pea thrives in any ordinary garden soil, and may be sown either in autumn or spring. Seed should be put in the ground 2 in. or 3 in. apart, and at a similar depth. It is customary to attribute failure with sweet peas to the ravages of birds, and certainly they do a great deal of damage. This may be guarded against to a great extent, however, by rolling the seed in red lead before putting it into the ground. When the young plants show themselves, and are likely to be nipped off, the surface soil should be liberally dusted with soot.

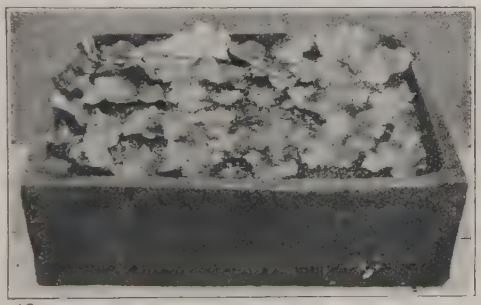
Sweet peas are usually seen in gardens trained up bean sticks placed against walls or fences, or in clumps. A method which has recently been put into practice with good effect, is to sow them in rows, a bean stick being driven firmly into the ground at each end of the row. At about 3 in. above the ground, a string is stretched from pole to pole, and the young plants lifted up, so that

their heads rest on the string. As they grow higher and need more support, other strings can be stretched across and so on, until they reach their full height. Practically, the only support to be seen is the pole at each end of the row, and even this may be hidden in a simple way by letting a fast-growing climber, such as the nasturtium, Japanese hop, or canary creeper, run up it. Unless it is desired to save seed of any particular plant for future use, the flowers should never be left on sweet peas until the seed pods form, as this weakens the supply of bloom. On the contrary, the blossoms should be cut almost before they are fully expanded, and then the plants will go on yielding a prolific supply of bloom right through the summer months. As regards sorts, all of those named "Eckford" are good, and there are several of these christened after different members of this famous grower's family. Apart from these, a few of the best are Blanche Burpee (white), Captain of the Blues, Venus (pink), Countess of Radnor (heliotrope), Cardinal (red), Primrose (pale yellow), Unwin, and Hemus.

17. A NEW BEDDING PANSY

The Bulbs of Spring. It is impossible to overestimate the value of bulbs in the garden, no matter whether they be the spring or autumn flowering kind. At present, the former are much more generally cultivated than the latter. This has been particularly the case during recent years, now that the custom of naturalising such things as daffodils, crocuses, snowdrops, and anemones, in the grass has arisen.

Hyacinths are usually grown in pots or glasses. For pot culture, a mixture of garden soil with sand and a little leaf-mould answers well, or the leaf-mould may be dispensed with if it is not readily available. October is the best month to plant the bulbs, and they should be barely covered with soil. A leading firm of growers says: "After potting, give one good watering, and then place the pots outdoors on a bed of ashes, cover with 6 in. of cocoa fibre, and leave them exposed to all weathers. When the bulbs have well rooted, and made about 1 in. of top growth, they may be removed indoors, first into a subdued light, until the foliage has attained its full green colour, and then in the sunniest situation at command in the greenhouse or conservatory. It is a good plan to place an inverted flower-pot over the young growths for a few days after being removed from the plunging bed, as by so doing they are protected from possible draught. Abundance of air, a moderately moist atmosphere, and plenty of water at the roots, are then necessary for early well-developed flower spikes."



18. PROPAGATING BEGONIAS FROM LEAVES IN A PAN

In quite small suburban houses, hyacinths in glasses are the rule rather than the exception. During the winter it is best to fill the glasses with rain-water to such an extent that the bottom of the bulb just touches the water. At first, keep the glasses in a dark place, filling them up with water as it evaporates; by this means, healthy root growth is promoted. By the time the glasses are nearly full of roots, they may be gradually exposed to the sun in a window. This treatment ensures large and healthy trusses of bloom. Hyacinths which have flowered in pots one year, will flower in a border for several years in succession afterwards, but the resulting flowers will not be so large.

The Narcissus (Daffodil). The daffodil [21] is undoubtedly the most valuable spring-flowering bulb we have in our gardens, and there is no capacity in which it cannot be used. It may be grown by thousands on banks, lawns, and in meadows, increasingly enormously, or it will flourish bravely on the sooty window-sill of a city slum. The best way to grow it in pots is to use three bulbs to a 5-in. pot. The soil it likes is ordinary garden soil, with a generous mixture of sharp sand. As daffodil bulbs vary so much in size a good general plan is to plant the bulb at one and a half times its own depth. After flowering, the bulbs should not be lifted out of the ground until the foliage has quite died down; but where this cannot be avoided, owing to the ground being required for other purposes, they should be carefully lifted, and re-planted in some spare corner until the foliage has quite withered, when they can be lifted and stored away until the autumn.

The narcissus family is divided into several important groups, including the Trumpet section, the Star daffodils, and the Poet's daffodils. They number several hundred varieties, ranging in price from a few shillings per hundred to twenty guineas a bulb.

The Brilliant Tulip. What the daffodil gives us in delicacy of colour the tulip supplies in brilliancy. It is not, however, adapted for culture in the grass, but does well in beds of soil as recommended for the daffodil. The genus is divided into three sections: Early flowering, May flowering (Gesneriana) and late flowering (Darwin). There is also a curious distinct breed called the Parrot Tulip, so named for its peculiar shape and colour. The tulip most suitable for town culture is Kaiser's Kroon, a brilliant scarlet tulip with yellow edges; while other good sorts, arranged in order of time of flowering, are: the Duc Van Thol group, Ophir d'Or, Proserpine, White Swan, Bouton d'Or, Gesneriana Spathulata, Golden Crown, Prince of Orange, May Queen, Salmon King, the Bride, and the Sultan, the latter approaching nearest to the much-sought-after black tulip.

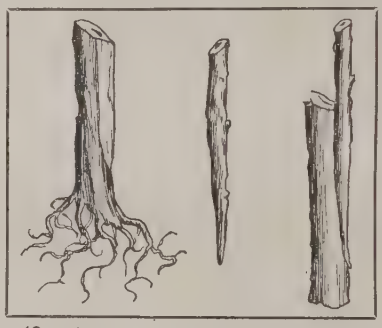
The Iris, Gladiolus, and Lesser Bulbs. Although different varieties of iris may be made to give flowers from the beginning of the year on into August, the great majority of them are spring flowering bulbs. These are what are known as the Spanish and English sections. September is the best month for planting the bulbs, which should be

put in deeply in any ordinary garden soil. There is a long list of sorts of all colours from white to nearly black, and splashed and marked with every conceivable hue. Some choice species of the iris include : Alata (Scorpion iris), Atropurpurea, Iberica, and Reticulata.

The spring flowering section of gladiolus bulbs is not a large one, only one or two varieties blooming as early as May. As, however, those which do not come into flower until June and July are planted at the same time as the ordinary spring flowering bulbs they are best included here. Gladioli require shelter from the wind, and also shade from the full heat of the sun. October is the best month to plant, though good results have been obtained with bulbs planted as late as Christmas. A layer of bracken or straw should be spread over them to protect them during the winter, while deep planting, say at a depth of six inches, also effects an insurance against damage by frost. The Bride (pure white) and Byzantinus (light crimson) are the best of this early flowering section.

Crocuses, snowdrops, anemones, scillas, alliums, dog's-tooth violets, chionodoxa, and muscari are the most important of the dwarfer growing spring flowering bulbs. Their culture is exceedingly simple. In fact they merely require putting in the garden or woodland, or wherever it is proposed to grow them, at any time during the months of October or November when the ground is dry. The rule of planting at the depth of a bulb and a half holds good in all cases.

Autumn Flowering Bulbs. Just as the spring flowering bulbs are planted in autumn, so should the autumn flowering bulbs be planted in spring. With the exception of the gladiolus, however, the culture of autumn flowering bulbs has been somewhat neglected, though their presence would be a great help at a time when gardeners are apt to rely very extensively upon the dahlia and chrysanthemum.



19. A METHOD OF GRAFTING ROSES

It is possible to get exactly the same effect with the crocus in autumn as it is in spring. Their culture is simplicity itself. They should be planted in any ordinary garden soil, and just covered with earth, or, if in pots as specimens, in ordinary potting mould. The best autumn flowering crocuses are the Asturicus varieties, which represent the mauves and purples in all shades ; Sativus, the purple saffron crocus ; Hadriaticus, pure white ; Zonatus, rose and orange ; and Speciosus, bright blue, recalling, when planted out in the grass, the beauties of the grape hyacinth in the spring.

The autumn flowering gladioli are varieties of the species known as Gandavensis, and they may be relied upon to provide those brilliant masses of scarlet so often needed but so rarely seen in the autumn garden. It is merely necessary to plant them out in March in good soil, and leave them to take care of themselves. They are somewhat shy of frost.

The belladonna lily (*Amaryllis belladonna*) is the most beautiful of all the autumn flowering bulbs, but it should only be planted on the south side of a house or wall, as it is not quite hardy in other situations. It grows nearly a yard high, with large lily-like white flowers, tinged with pink towards the centre. It needs deep, fairly rich soil, and if the bulbs are planted in autumn, which is the best time to ensure a display of bloom the following year, they should be protected with a layer of fibre during the winter. They soon establish themselves and will bloom freely every year.

The tiger flower (*tigridia*) should, as far as culture is concerned, be treated the same way as the gladiolus. The flowers are six inches wide, bright red in colour with crimson spots, and the plant attains to a height of 2 ft. or more. Each flower only lasts a day, it is true, but a succession of flowers lasting in all nearly two months are borne on the same stem.

Other autumn flowering bulbs include Crocosmas ; Sternbergias (the best authorities say that this is the lily mentioned in the Bible) ; Leucojum ; the autumn flowering Scilla.

The Dwarfer Flowers of the Garden. The proper place for dwarf flowers in the garden is obviously in front. Many of them are of great value for edgings, while others help to form a carpet at the foot of taller growing things.

Although the violet is frequently found wild in the hedgerows and copses of the country, the practice of cultivating it, either for private use or for market purposes, is not a general one. The French grower thinks nothing of having two or even three acres of ground covered with violets, while the English grower is content with a few square yards. As violets like shade, they are essentially suitable for carpet plants, and they thrive in any moderately good soil. It is well not to leave them for more than two years in the same spot, however, as they deteriorate in quality after that time. They are best planted in May for the following season's display, a little manure from the hotbed being forked in when planting. The most popular sorts are Neapolitan, Marie Louise, La France, the Tsar, and Princess of Wales. Belle de Chatenay is one of the best white sorts.

Pansies, Lily of the Valley, and Lobelia. The pansy [17] is a sister of the violet, as both belong to the same genus (Viola). It is one of the easiest garden flowers to grow, and may be used as an edging or to cover the surface of a bed of roses, or other flower. Pansies may be planted either in autumn or spring, the former for early flowering. They should be put in about 9 in. apart. To obtain plants from seed in the open air it should be sown in the middle of summer (say, July), and the little plants transferred to the flowering beds in the ordinary way in the autumn, when they will bloom the following spring. Both the violet and the pansy are subject to attacks from green fly, and, occasionally, red spider.

The lily of the valley is so frequently seen forced in pots in company with other exotics in florists' shops in the middle of winter that the fact that it is a perfectly hardy garden flower is apt to be overlooked. It can be grown almost anywhere, and suburbs near to the smoke of London appear to suit it well. The corms should be planted in October, just at the time when the spring flowering bulb planting is going on, and the bed in which it is proposed to plant them should have a liberal dose of leaf-mould mixed with the surface soil. The corms

should be placed about 3 in. apart, and just covered with soil, and they will start into growth in early spring. The lily of the valley is one of the best solutions to the ever-recurring problem of what to plant in the shady side of a town garden.

The dwarf section of the lobelia family is known technically as *Lobelia Erinus*. It is the familiar little blue flower so often seen as an edging plant in gardens, and also as a prominent feature in window-boxes, for both of which uses it is admirably adapted. The lobelia is only half-hardy, and requires the protection of a greenhouse in winter. The plants can be raised from seed sown in boxes of light soil at Christmas-time, or thereabouts, and given a gentle heat. If the common mistake of sowing the seed too thickly has not been made, they will be ready for putting out in May without further transplantation, and will continue to bloom until cut down by autumn frosts.

20. BORDER CARNATION (TROJAN)

Virginian Stock, and Other Dwarfs. The Virginian stock is one of the very hardiest of dwarf growing annual flowers, adapted for an edging, and its culture is simplicity itself. It is only necessary to go out into the garden on a bright day after the rain during April, and drag a stick along the edge of a bed or border, so that it leaves a furrow behind it. Into this furrow sprinkle the Virginian stock seed gently, and just cover it with the earth which has been disturbed. In a very few weeks a substantial edging, from 4 in. to 6 in. in height, will make its appearance, covered with thousands of tiny flowers — red, white, or mixed, according to the variety used. One sowing will bloom for weeks. Fresh rows should be sown at intervals an inch or two before or behind the original edging.

The most useful variety of the Alyssum family of dwarf-growing plants is the sweet alyssum, a white, fragrant little flower, useful as an edging, or charming in effect if sown to form a broad sheet, and flowering all through the summer and well on into the autumn. It is best sown in the open air in spring, and if the precaution of sowing thinly is taken there is no need for transplanting.

Nemophila is another of the dwarf hardy annuals, and should be treated in the manner already described for this class of flower, with one difference. In addition to sowing in the spring for summer flowering, a sowing should be made in the autumn, where tulips and other of the taller flowering spring bulbs are being planted. The nemophila will then bloom with them in the springtime as a carpet of delicate pale blue or white as the case may be. Nemophilas will flourish in any soil, and so are eminently adapted alike for culture in town or country. The plant should never be used, however, where cats are likely to cause any trouble. For some mysterious reason, cats are particularly fond of this plant, and have been known to travel a long way to get at a garden in which there was a bed of it. As their appreciation takes the form of lying down and rolling over and over in it this naturally means the destruction of everything in the bed.

The garden forget-me-not (*Myosotis dissitiflora*) is probably the most useful of all the dwarfer flowers of the garden, inasmuch as it blooms in spring, and so forms a carpet for the bulbs. Seed may be sown in the autumn at the same time, and in the same beds, as the spring-flowering bulbs are put in, and they will all come up and flower together. The plants are easily propagated by digging them up and dividing the roots during the flowering season, or if they are allowed to remain where they are the seed will ripen, drop off, and sow itself during the late summer months. This is not the forget-me-not of the stream side, about which poets write so much, the latter being known as *Myosotis palustris*.

Other dwarf flowers of spring are *Arabis alpina*, *Limnanthes Douglasi*, *Saponaria calabrica rosea*, and *Silene pendula*, while the stonecrops are at all times useful, apart from their place in the rock garden, in covering up odd corners. The flowers just mentioned are all hardy annuals, and merely require the treatment already set forth for such things.

21. "EMPEROR" DAFFODIL
For bed, pot, or window-box

Carpet Flower-beds. Upon few subjects has more wordy warfare been waged than that of carpet bedding. The extreme school of "wild gardeners" execrate it, and there is no doubt that, if carried out to excess, these flat beds made up into carpet-like designs are both dull and uninteresting. The rational gardener, however, will be quick to recognise that there is a place for them in every garden that has any pretensions to size. Carpet beds may be of any shape the designer has a fancy for, but the pattern is usually regulated by the size and shape of the place in which the bed is to be put. A very good plan is for the gardener to work out designs on paper, drawing them to scale, during the long winter evenings. A good idea of what the general effect will be like may be obtained by colouring these plans as near as possible to the hue of the plants it is intended to employ. Before proceeding to cut out the bed it is best to mark an outline of it in whitewash.

The majority of carpet-bedding plants are raised from seed, sown in boxes in March, and subjected to a bottom heat of about 80°. One of the most important plants for carpet bedding is the alternanthera, of which several varieties are useful. They range in colour from yellow to brownish-red, the variety aurea being a brilliant yellow. The pyrethrums, or golden feathers, are another mainstay of the carpet bedder, and the different varieties give him grey, pale green, and gold for his beds. Antennaria

is the plant generally employed to get the delicate silvery white effect so often seen in the best carpet beds, while for very deep red effects the beet is occasionally employed with advantage. The varieties of lobelia mentioned on the previous page are valuable aids to carpet-bedding. No carpet bed would be complete unless it contained some of those curious flat rosette-like plants called *Echeveria secunda*. They are raised from seeds sown on fine soil in gentle heat, and merely require protection from frost in winter.

Where a centrepiece is desired for a carpet bed, and such a thing is often an improvement, it is best to employ the fishbone thistle (*Chamæpeuce cassabonæ*), a graceful plant, with shining dark-green leaves marked with white and brown.

The following are in general use as carpet bedding plants, but they require no special treatment: *Alyssum maritimum*, *Mentha pulegium*, *Iresine lindeni*, and *Sedum glaucum*.

Summer and Autumn Bedding Plants. Among gardeners the term "summer bedding plants" is understood to comprise those plants which, although invaluable for giving us a display of bloom, say, from May until September, are too delicate to withstand the rigours of our winters, and need the protection of a frame or greenhouse, or at lest a shed, if they are to be kept alive. Until comparatively a few years ago, summer bedding was confined to the laying down of strips of blue lobelia, scarlet geraniums, and yellow calceolarias, which occurred in garden after garden with never varying monotony; but things have now happily altered for the better, and a wider range of effect is possible. In the genial climate of the south and west of England some of the plants described hereafter as needing protection during the winter may remain in the open ground all the year round with impunity, but this favoured area is of such small extent that for practical purposes it is necessary to treat summer bedding plants as being only half hardy. The flowers enumerated hereunder are those most generally in use for the purpose mentioned, and may be supplemented, where opportunity affords, by those mentioned in other sections.

The Geranium, Fuchsia, and Begonia. The geranium, as most people know it, is not a geranium at all, but a pelargonium; it originally sprang from the wild geranium, but has been crossed with various species in order to obtain fresh varieties. It is the most popular of all summer and autumn bedding plants, and one of the easiest to cultivate well. It will grow in any ordinary garden soil, and is increased by taking cuttings, or slips, when the flowering season is practically over—say, in September. These slips should be cut off the parent plant at a very acute angle with a sharp knife, and should be put into little pots containing some fairly good soil, and with a pinch of sand at the bottom of the hole where the cutting is stuck in. As soon as there is any fear of frost they should be got in under glass, and they will quickly root and be ready for planting out the following May. Cuttings may also be struck in the spring, in slight heat, and will be ready for planting out at practically the same time, but they will not make such sturdy plants. Very little water should be given during the winter.

Fuchsias thrive in soil similar to that suitable for geraniums. They are, however, propagated in a somewhat different manner. It is customary to take old plants which have been stored in a cellar or somewhere else away from frost during the winter, and start them into growth in the heated greenhouse. When the young shoots appear, and are about two or three inches in length, they should be taken off and potted up as directed for geraniums. They should be thoroughly hardened off by exposure to light and air before being planted out. In some gardens, especially near towns, the buds of the fuchsia have a provoking habit of dropping off instead of opening into flower. The general cause of this is insufficient water, or, if the fuchsias happen to be growing in pots instead of in beds, it will probably be found that they are "pot bound"—that is to say, the pot is not large enough to contain the roots. The most reliable fuchsia for town gardens is known as *Riccarboni*, which does well in London suburbs in the open.

The begonia of so much value for summer and autumn bedding is what is known as the tuberous-rooted begonia. It is best raised from seed or leaves sown in early spring in pans [18] or boxes in sandy soil and brought on in a temperature of not less than 60°. In three weeks or a month's time the plants will be ready to be put into pots, after which they should be gradually hardened off for planting out in June. Great care should be exercised in the sowing, as the seed is so very minute. In a rich, light soil begonias will continue to flower until cut down by frost. When this happens it is usual to lift them up, and store the tubers which will be found to have formed at the roots, in silver sand in a dry place. These tubers can be started into growth again in the spring. There are many sorts, in all shades of white, yellow, salmon, and red, and some double ones [30].

Dahlias, Calceolarias, and Other Bedding Plants. When the summer begins to wane there is probably no more important bedding plant in the garden than the dahlia, as it forms stout bushes three or four feet in height, giving a generous supply of bloom for cutting, right into the very late autumn. There are four principal kinds: the double dahlia, which is the old-fashioned almost spherical-shaped flower so often found in cottage gardens; the pom-pom, which is a smaller edition of the double dahlia; the cactus, distinguished by its almost claw-like petals; and the single dahlia. Dahlias are usually propagated from cuttings, which are obtained by starting a tuber into growth in a heated greenhouse in January or February, and taking off the cuttings as the young shoots appear. These are then treated in the manner described for seedling begonias. When the dahlias are thoroughly hardened off, and ready for planting out, a stick some four feet in height should be pushed into the ground at the side of the hole dug to receive each plant, and to this stick the young dahlia should be tied sufficiently tightly to prevent it being swayed about by the wind. After flowering, the bulbs should be lifted and stored in a box of soil in a frost-proof place during the winter.

The yellow calceolarias are a familiar sight in the summer bed. They are propagated by cuttings taken in the autumn in sandy soil, and placed in a cold frame, where they will root during the winter, and so be ready for planting out with the rest of the bedding stuff [22].

The canna is as effective in the summer garden for its foliage as for its flowers, most of the varieties having rich brown leaves. A group of cannas in the centre of a large bed is particularly effective, reaching, as the plant often does, to a height of six feet. They are propagated by spring cuttings, in the manner described for fuchsias, or by dividing the old roots, and potting them up. They need a sunny position, or they fail to develop. The best sorts are Antonin Crozy (crimson), Antoine Chantin (salmon colour), and Paul Bert (yellowish red).

The heliotrope is best known under its old-fashioned name of "cherry pie," and the little

A STATELY TENANT OF THE GARDEN

THE GLADIOLUS WHICH FLOURISHES IN SUNLIGHT

This photograph and that on page 5949 are by courtesy of Messrs. Sutton & Sons, Reading

flower is a great favourite because of its delicious perfume. It is propagated in the same way as the fuchsia, or forced from seed and hardened off. It is generally a failure in moist soil, and, when desired there, should be kept in the greenhouse.

Petunias and Tobacco Plants. The petunia is a hardy annual, raised from seed sown in heat in February, and planted out in May. Particular care must be taken in planting out, as the roots of the plants are very brittle, and liable to damage if they are at all carelessly handled. Seedling plants often yield bloom with very curious markings; and if it be desired to perpetuate these, cuttings should be taken in August, and placed in pots or a frame in soil which is well mixed with rotten manure and kept moist. They must be wintered in a cold frame, and care taken that the frost does not get at them. Good bedding sorts are Countess of Ellesmere (crimson with paler throat), Delicata (white with purple stripes), and Doctor Hogg (purple with white throat).

No garden is complete without its tobacco plants. They should be treated as half-hardy annuals, and raised from seed sown in heat in February, when they will be ready for planting out with the rest of the summer and autumn bedding stuff. The one most frequently met with is *Nicotiana affinis*, particularly sweet scented in the evening, and reaching a height of about two feet. A taller variety is called Sylvestris—three feet in height, the flowers of which do not shut when exposed to the full glare of the sun, as is the case with Affinis. A very interesting variety is called Sanderæ, having red flowers.

The Hardy Ferns. In order to grow hardy ferns to the best advantage, they must have a shady position in the garden. It is not, of course, impossible to grow ferns in the sun, but it is hopeless to expect them to do well there, as they soon get scorched up. Ferns dislike being moved; hence, to get the best results, the fernery should be established at some spot in the garden where it is likely to remain for a number of years. A sloping bank makes an ideal spot for a fernery; but, no matter where it may be, it is essential that the ground should be well drained. Ferns will not flourish when they have a lot of stagnant moisture about their roots, though, at the same time, the majority of them thrive admirably in the neighbourhood of a running brook or stream. The ideal soil for the fernery is a mixture of good loam and peat, the former predominating.

Ferns are usually propagated by taking the seeds, or spores, which are found upon the backs of the fronds, and spreading them carefully upon the surface of a lump of peat, keeping the peat thoroughly moist, when the majority of the seeds will successfully germinate. Those ferns which have running roots, however, may be divided in the usual manner. In order to ensure that fresh, bright green appearance so much to be desired in ferns, it is necessary that the foliage should have plenty of water. In small indoor ferneries this moisture is often supplied by the introduction of a small fountain. Out of doors the best substitute is frequent soaking with a hose the rose of which has holes of the smallest size.

There are several varieties of spleenwort (asplenium), ranging from one to two feet high respectively. The most important is the black spleenwort (*Adiantum nigrum*), which, in addition to being grown among other ferns, may be planted with success at the foot of such shrubs as azaleas to act as a carpet. Its fronds are also useful when bouquets have to be made up, or to mingle with cut flowers for general decorative purposes.

Royal and other Popular Ferns. The Royal fern (*Osmunda regalis*) is rightly named, as it is the largest and most imposing of all our native ferns. It has been known to attain a height of eight feet, though its average altitude is not so much as this. It wants damp, peaty soil, and may, in fact, be planted with its roots in water in a shady spot. There are several varieties, natives of North America, useful where large collections are being made, but otherwise not of great importance.

One of the most popular ferns is Hart's Tongue fern (*Scolopendrium vulgare*), deriving its name from the shape of the fronds. Like most other ferns, it likes shade and moisture, but has the notable characteristic of thriving particularly in a soil containing lime. It is attractive when grown in pots for decorative purposes.

The Lady fern (*Athyrium*) is another family of ferns much overladen with valueless varieties, but the type is worthy of cultivation under orthodox conditions in the fernery, or among evergreen herbaceous plants. It dies down during the winter, and therefore requires no water then.

A very useful, hardy little fern is Polypody (*Polypodium*), which may be grown on walls or in rockwork, the fronds of which are green all the year round. It is one of the easiest of ferns to propagate, being easily increased by dividing the roots—an operation best carried out in the spring time. It prefers a liberal admixture of sand in the soil in which it is grown.

The Shield ferns (*Aspidium* and *Polystichum*) are eminently suited for culture in town gardens, as they will thrive in a comparatively poor soil provided they have plenty of water during the hot months. The shield ferns are particularly useful for planting under trees, where there are often bare spots upon which grass refuses to grow. The well-known Holly fern is a variety of this family, of which over 100 members are found in catalogues.

There are several other families of ferns, individual members of which are worthy of a place in our gardens where a speciality is being made of the fernery. The system of nomenclature by which they are distinguished is a very confusing one. In any case, too many ferns in a garden are a mistake, and unless the place is of any considerable extent it is perhaps a mistake to lay down a fernery at all.

Tall Plants. When first laying out a garden, or altering the appearance of an existing one, the proper use of the taller plants is a matter which requires very careful consideration. In a small garden the employment of many tall plants is a mistake, for not only do they overshadow the humbler plants growing at their feet, but their general effect is to make the garden appear smaller than it really is. In fact, the only positions in which tall-growing flowers can be employed with advantage in small gardens are in the borders against a wall or fence. Even then, if there are many of them, they give the place a somewhat military appearance, unless, as often happens in poor soils, their weak stems fall untidily sideways.

In large gardens the tall flowers can be used in profusion almost everywhere, to break up the monotony which would otherwise be produced by the dead level of height of about 2 ft., which is attained by so many of our fairest garden flowers. They may be used in clumps in borders, or in the centres of large beds, or they look particularly

charming in beds by themselves set in the middle of an expanse of turf, so that they can be admired at a little distance.

Hollyhock and Larkspur. The hollyhock is one of the most useful of the tall-growing flowers, and, although it is sometimes called old-fashioned, it is without a rival for effectiveness in poor soils. It is no uncommon thing to find these plants self-sown in gardens, but such varieties are best relegated to the wild garden. The choicer sorts, however, deserve to be cultivated everywhere. There are two ways of growing hollyhocks. One is to sow seed in autumn in a cold frame, protecting it during the winter and putting the little plants out in spring, and the other is to sow in February in heat, and plant out in spring or early summer with the bedding stuff. The former method usually gives sturdier plants. The average height of the hollyhock is about 6 ft. or 7 ft., though there are many instances on record where they have attained an altitude of nearly 20 ft. Nurserymen keep a good many sorts, varying in colour from white to a very dark crimson, which is almost black, and including yellow. There are also double-flowered sorts, all of which are worth growing where there is sufficient space.

The Garden Foxglove. To the novice who knows the foxglove only as a tall, pale purple plant of our lanes and hedgerows, and is apt to regard it as almost a weed, the idea of growing it in a garden may seem peculiar. As is the case with many other flowers, however, it has been taken in hand by nurserymen, who have raised many new and valuable sorts. Foxgloves require a good deal of space, however, and for that reason must be introduced into a small garden with care, as they soon develop a habit of sowing themselves. Hence, under such circumstances, they are best used as specimen plants in large beds. The method of culture is similar to that already given for the delphinium, and the white variety is the most imposing, often attaining a height of 6 ft. Canariensis, with flowers of a brown colour, and grandiflora, having yellow blooms, are two interesting sorts if variety is desired, while there are several sorts with spotted flowers known as gloxinia-flowered foxgloves, which are interesting.

Lupins. It is the perennial lupin which is the tall-growing variety of lupins. The culture of lupins is simplicity itself, as the seed simply needs to be sown in any garden soil in spring, and the plants thinned out when they are a few inches in height. The thinning should be drastic, for

22. CALCEOLARIA

The tall-growing larkspur (Delphinium) must not be confounded with the ordinary larkspur of the garden. Though both belong to the same family, the tall larkspur is a perennial [29], while the ordinary larkspur is an annual, and must be sown afresh every season. The perennial larkspurs can be raised from seed, either by sowing in heat in the early spring and planting out the seedlings where they are to flower, or by sowing in the open ground in the summer, in which event good, strong plants will be obtained to bloom the following year. Though the larkspurs do best in loam, they may be made to thrive in a light, sandy soil, provided it is well manured and freely watered.

The many new hybrids embrace all sorts of colours from pale yellow to purple and red, but the rich blue sorts are, perhaps, of the greatest value for general garden purposes. Their average height is about 5 ft., though some of the newer hybrids are much taller. As these larkspurs increase rapidly, they should be dug up and the roots divided every four or five years. When once they have started flowering, they can be made to continue to do so for several months by cutting off a flower spike as soon as it has done blooming, when another one will immediately begin to make its appearance from the root of the plant.

the lupin is of bushy habit as growth proceeds. Though, strictly speaking, perennials, lupins frequently fail after three or four years, but they are so easily grown from seed that this is not a matter of great importance. The best sort, especially in a poor soil or a rocky corner, is the tree lupin (*Lupinus arboreus*), a stout, bushy plant with stiff spikes of yellow flowers, reaching to a height of 4 ft. or more. *Lupinus polyphyllus* is an even taller sort, with purple-blue flowers, and of this species there is a white variety—Albus. All the tree lupins are excellent plants to employ in large places where the formal garden melts away into the woodland, and the soil is probably not so rich or constantly worked as it is nearer to the house.

Flame Flower or Torch Lily. This is a valuable plant of many names. It boasts two Latin ones—*Kniphofia* and also *Tritoma*—while it is also known in different parts of the country as the torch lily, and sometimes as the red-hot-poker plant. It is a hardy perennial, cultivated in the same way as the delphinium, and at its best in a deep, rich soil, though it will thrive in practically every garden. When it is desired to increase the plants, they should be taken up and the roots divided, either in spring or autumn. The most popular variety of the flame flower is *Kniphofia aloides*, attaining a height of 6 ft. or more, and

having long flowering spikes of particularly brilliant scarlet flowers, shading to orange. It is the peculiar brilliance of the flower's spikes which has earned for it the name of red-hot-poker plant. An excellent plan to adopt with it, though it is rarely put into practice, is to mass it near the edge of a lake, in company with bamboos and pampas grass, where it gives a charming effect in summer and autumn.

The Despised Sunflower. Although many people pretend to despise the sunflower (Helianthus) [25], to do so practically amounts to a profession of ignorance regarding the plant. Certainly the ordinary annual sunflower, frequently met with in suburban cottage gardens, is not a plant which it is desirable to employ extensively, as it takes a lot of nourishment out of the soil. Several of the varieties of perennial sunflowers, however, are among the most valuable of the taller flowers of the garden, as the brown-centred yellow blossoms give a blaze of colour equalled by few other flowers of this class. The flowers are not particularly large, being in most of the varieties about 3 in. in diameter, but they are borne in great profusion. Their best use is, perhaps, singly, in beds, as they are of bushy habit, and, consequently, take up a good deal of room, though where there is a large shrubbery they may be massed with good effect. They are raised from seed in the same way as delphiniums, and may be sown in the open air early in April, where they are to flower. It is well to dig them up and part them every three years, as they increase very rapidly, and are apt to get out of hand if left undisturbed for a period longer than this. The best sorts are: Giganteus (10 ft.); Orgyalis (8 ft.); Decapetalus (6 ft.).

23. DUTCH PEARL AZALEA
For the greenhouse

Other Tall Flowers. Though most of the hibiscuses are generally considered to be greenhouse flowers, there are several of them suitable for open-air culture in favoured spots, particularly in the gardens in the south and west of England, and where deep and rich soil is available. In such circumstances, the best way to grow them is to treat them as half-hardy annuals, sowing the seed under heat in February, and planting out in the late spring. The variety most likely to succeed is *Hibiscus manihot*, which sometimes reaches a height of 5 ft. or more, and has yellow flowers, with a dark crimson centre. Another hardy hibiscus, which is often classed as a shrub, is Syriacus (the Rose of Sharon), reaching to a height of 8 ft. or 9 ft. under favourable circumstances. It makes a good centrepiece for a bed on a lawn, but should be used sparingly. There are hybrids with flowers of all colours from white to crimson.

Humea elegans is a half-hardy biennial plant—that is to say, seed must be sown one year for it to bloom the next, after which it dies. The seed should be sown after the middle of the summer in pots of rich soil, and given an occasional dose of liquid manure during the winter, as only by feeding them liberally can the best results be obtained. About a year after sowing they will be ready to plant out, and they may be used either at the back of the border, as a specimen on the lawn, or as centrepieces to a bed. They range from 5 ft. to 8 ft. in height, according to the soil and position in which they are grown, and have long feathery-like spikes of red-brown flowers.

In addition to the foregoing, many beautiful flowering shrubs may, with advantage, be introduced into bed and borders, instead of confining them to the shrubbery. Such introductions should be made with care, as if they are planted in profusion the tenderer plants will soon be starved to death. Shrubs which are suitable for such a purpose include the hydrangea, pæony, *Daphne mezereum*, some of the choicer rhododendrons, magnolias, flowering currants, spireas, and the mock orange.

How to Manage a Glasshouse. Glasshouses are roughly divided into three sections—the cool house, the intermediate house, and the hot house. In the cool house, no artificial heat of any sort is employed. The intermediate house, which may, perhaps, be more readily recognised by its popular name of "heated greenhouse," is one in which the winter temperature is always kept at least 15° above freezing point, and the hothouse, or stove, where most of the exotics are grown, should always be held up to a minimum of 10° above this. All houses require the same sort of treatment in their general management.

Hot water is the universal system by which houses are heated, and soft water, if it can be procured, is the best to employ, hard water quickly fouling the pipes. With the ordinary upright boilers, coke is practically as good as coal for stoking purposes, and has, at the same time, the merit of being more economical. It will burn longer, however, and maintain a regular heat better, if it is first slightly damped and mixed with coal dust. This latter is the best method to employ when making up the fires to last all through the night, as, if once the temperature of the house is allowed to fall below the minimum point at which it ought to be maintained, fatal results may follow. Every greenhouse should be furnished with a maximum and minimum thermometer, the tube of which contains tiny glass indexes, one of which indicates in the morning the lowest point to which the temperature has fallen during the night, while the other shows the highest point touched.

24. LAYERING CARNATIONS

Although the purpose of greenhouses is avowedly to grow tender plants, it must not be forgotten that the more a greenhouse is ventilated, the healthier will be the condition of its occupants, provided the atmospheric conditions are right. On dull, wet, or foggy days, but little air can be given, but when the

weather is bright and warm, the ventilators can be kept open all day long, provided the right temperature is maintained. Cleanliness is an essential feature in the management of a greenhouse. Before any potting is done, the pots should be scrubbed perfectly clean, and this cleanliness should be maintained after they are filled by washing them over outside at intervals of a week or two. The shelves of the greenhouse should be washed down at least once every three weeks, and the glass itself, as well. This operation affords opportunity for looking over the plants. Such a house cleaning, if it may be so termed, not only benefits the plants themselves, and improves the appearance of the house, but it also helps to keep away insect pests.

Never use cold water in a hothouse when watering plants. It should always be a few degrees higher in temperature than the atmosphere in the house. The best time to water plants is about the middle of the day in winter and the evening in the summer-time. In the spring and autumn, watering may be done early in the morning. Greenhouses in very sunny positions will require to be shaded in the summer-time from the glare of the sun in the middle of the day. This shading usually takes the form of a blind which can be pulled down over the roof and let up again when necessary. Five or six hours in the middle of the day is generally long enough for this shading to remain down, provided the sun does not go in, in which case it should be pulled up immediately. In the place of these blinds, or shades, a mixture of whitening and water is sometimes thrown over the sunny side of a house, but this rough and ready method of shading has two drawbacks—it whitens everything with which it comes in contact, and cannot, moreover, be removed instantaneously during a cloudy time.

25. DWARF SUNFLOWER
(*Helianthus multiflorus*)

The Flowers of the Greenhouse The proper arrangement of the greenhouse is one of the gardener's most difficult duties, especially if the space under glass at his disposal be limited.

Where there are two greenhouses only, it is certainly better to devote the larger one entirely to show, and keep the smaller one for rearing seeds and cuttings—that is, assuming that one is a warm and the other a cool greenhouse. The ideal way is, of course, to have houses of three different temperatures in duplicate, one for show and the other for use, looking at it from the gardener's point of view. So much depends, however, upon the likes and dislikes of an employer that no definite rules upon the subject can be laid down.

For the purposes of this article, the word "greenhouse" is intended to mean the general purpose, or intermediate house, the temperature of which is not allowed to drop below 40 deg. in the winter. Practically all the summer and autumn bedding plants mentioned on page 5946 may be flowered in the greenhouse, and bloom had several weeks earlier than if they are planted out in the open ground. Daffodils, tulips, lilies of the valley, and all the other spring-flowering bulbs may readily be forced on in boxes for cutting or table decoration.

The Most Important Greenhouse Plants. The abutilons are a family of fairly large sized shrubs requiring a good deal of room, and therefore out of place in a small greenhouse. They are raised from seed sown in early spring, or from cuttings of old plants taken at the same time. As soon as the plants are big enough to handle they must be repotted into larger pots, and the process repeated at intervals until the plants are full grown; in this state they often attain a height of 6 ft. The best sorts, especially for commercial purposes, are Boule de Neige (white), Royal Scarlet (red), and Golden Fleece (yellow).

Acacia. The acacia is better known by the name of mimosa, and is best raised from seed sown in spring in the ordinary way, as attempts to propagate it from cuttings are rarely successful. There are several sorts, all very much alike, but the best for general purposes is *Acacia dealbata* where space is of no object. It is this variety which is sold in such huge quantities in the streets of towns and cities. A lot of it comes to London from the South of France, but English grown mimosa usually realises an average price of 4s. per "pad." All the acacias flower in spring time, except Platyptera, which is an autumn-flowering variety.

Azalea. The azalea in the greenhouse is now usually grown in the form of the small pot plant, so familiar in the florists' windows. Although a hard wooded plant, its culture is very similar to that of the camellia, except that it should be grown in pots instead of tubs. It flowers during the early spring, and should be stood out about June, giving plenty of water so that the wood can ripen properly. In the south and west of England some sorts grow into bushes in the open. *Azalea mollis*, Indica, Fielder's White, and Dutch Pearl [23] are the most useful sorts. Good market plants, the bulk of which come from Ghent, fetch normally from 24s. to 30s. per dozen.

Begonias are among the most valuable winter-flowering plants of the greenhouse, while there are in addition some sorts equally desirable on account of their brilliantly marked foliage. They are not at present seen to a great extent in private greenhouses, but they are largely grown for the market. They are best propagated by cuttings taken in the spring, and potted up in tiny "thumb" pots, in loamy soil, with a good layer of silver sand on the top of it. If allowed to have a warm corner in the greenhouse for the first month or two they will make rapid growth, and when the pot is full of roots the plant should be shifted into a 5-in. pot, where it will flower the following winter. The best sorts are Gloire de Lorraine, President Carnot, Winter Cheer, Metallica, and Semperflorens, while of the fine foliage sorts the varieties of Begonia Rex are mostly sought after.

Calceolaria and Camellia. The shrubby section of calceolaria used for bedding out has already been dealt with, but the herbaceous varieties are equally important, as they include many choice new hybrids for specimen and exhibition purposes. They must be sown one summer to bloom the next, in very finely powdered loam and sand, moistening the soil first and sprinkling the seed very finely over the surface. The box, or pan, in which the seed is sown must then be covered with a sheet of glass, and put in a moist corner of the house. As soon as the plants are large enough to he handled they must be transferred to "thumb" pots, and afterwards to those of larger size, in which they are to bloom. As herbaceous calceolarias like moist and shade care should be taken to shield them from the direct rays of the sun. Practically every nurseryman of any note has his own choice list of hybrid calceolarias, of all sorts of colours and markings.

By far the best way to grow the camellia is in a tub. Although essentially a greenhouse plant, it can be moved out of doors the summer after it has done flowering, and its home in the greenhouse occupied for a few months by something else. The best time of the year to start camellia culture is in August, when the plants should be repotted, in a mixture of loam with a little peat. In the case of the camellia, repotting does not necessarily mean putting into a larger pot, for it is one of those things which seem to do best without too much root room. The plants should be brought indoors in October, and given an occasional weak dose of liquid manure, and they will flower from the end of November onwards. The well-known white camellia is called Alba Pleno, and is the easiest of all to grow. The best pinks are Lady Hume's Blush and Beauty of Waltham; of the reds, C. M. Hovey and Donckelaari. Although there is a huge demand for market camellias it is not a very paying branch of horticulture, as the prices run low. From 1s. to 1s. 6d. per box of two dozen blooms is the average price.

26. STEPHANOTIS
The sweetest-scented flower of the greenhouse

Cinerarias. These are decorative plants of many hues and colours, and are best raised from seed every year. This seed may be started in a cool frame in light, sandy soil in the month of May, and the seedlings transferred to "thumb" pots as soon as they are large enough to handle, repotting them once more as required. As soon as the first sign of frost makes its appearance they must be transferred to the greenhouse, but not the hottest part, as they are satisfied with quite a moderate temperature. They will bloom from Christmas until quite late in the spring. There is generally a good demand for them at Covent Garden during the winter months, their chief use apparently being to stand on the dining-tables of hotels, a purpose for which they are well adapted, as they last in bloom a long time.

Hardy Greenhouse Flowers. In the south and west of England, the hydrangea is hardy, but it is generally grown as a greenhouse plant. In its popular form, and the one in which it is always seen on the market, it is a one-stem plant with a big head of bloom. These plants are obtained by taking the stout shoots of old plants and treating them as cuttings, in any ordinary potting soil, when they strike readily and make rapid growth. The natural colour of the flowers is pink, but they may be induced to show blue blossoms by soaking the soil with alum water, or growing them in soil in which there is naturally a good deal of iron. Limited market demand at 10s. to 15s. per dozen.

The heaths are best grown in a mixture of peat and silver sand. They are useful for table decoration in winter, and are not difficult of culture if kept liberally watered and well drained. The most popular sorts for greenhouse culture are Gracilis, Hyemalis, and Ventricosa. There is a constant market demand for them, as, in the hands of an amateur, they usually bloom to die, and, in the winter plants in 5-in. pots may realise anything from 9s. to 20s. per dozen. There are over 500 sorts, mostly differing but slightly.

Primulas, Carnations and Chrysanthemums. The seed of the hybrid Chinese primulas should be sown in June in well sifted soil composed of loam and leaf mould, and treated in the manner described for calceolaria, taking care to keep them in the dark until the seed germinates. Their final potting should be into a 5-in. pot, and they will bloom from November until spring. The flowers are all shades of white, red, blue, magenta, and pink. A branch of the family much grown is *Primula obconica*, but it should never be handled except with gloves, as it is prone to set up an irritating skin disease.

Hardy flowers cultivated in the greenhouse include the carnation and chrysanthemum. Their culture is practically the same as that recommended for out of doors. The species of carnation for greenhouse culture is known as the tree carnation. It may be had in flower in either autumn, winter, or spring, according to the time the cuttings are taken, hence it is easy to arrange for a succession of bloom. Cut flowers of winter carnations fetch anything from 1s. to 2s. 6d. per dozen. For market purposes, chrysanthemums realise 3s. to 4s. per dozen bunches, of about two dozen blooms each, but the large specimen chrysanthemums are marketed at anything from 2s. to 5s. per dozen blooms.

The Ferns of the Greenhouse. Most of the maidenhair ferns thrive well in greenhouse temperature, especially the popular variety *Adiantum cuneatum*. Large quantities of maidenhair ferns are grown for market purposes, chiefly by division in spring, or from spores, but they need special houses for their culture if they are to be profitable; this particularly applies to the small maidenhair ferns which are frequently to be seen hawked about the streets in "thumb" pots, and for which the market price is about 1s. per dozen.

The peculiarity of the hare's-foot fern (Davallia) is the curious, brown creeping stems which lie on the surface of the soil, and give rise to the popular

name. The ferns are well suited for a small greenhouse rockery, as they are shallow rooting things, and may be well grown in peat and moss. One of the varieties, Mariesi, comes into this country in large quantities from Japan, rolled up in the form of balls, and twisted on wire into the shape of frogs, monkeys, and other devices. These are the well-known "Japanese fern balls," and, given gentle heat and plenty of moisture, soon cover themselves with green shoots. They are interesting curiosities, but are of little horticultural value.

The following ferns are also well adapted for greenhouse culture: *Asplenium bulbiferum, Lastrea patens, Nephrodium molle, Polypodium aureum, Pteris argyraea,* and *P. tremula.* The same methods may be applied to almost every fern that requires the aid of artificial heat to bring it to perfection. A general mixture of loam, leaf mould, and sand should be employed, and the mixture carefully gone over to see that it is not lumpy.

Repotting young ferns, or the separation of the roots of old ones, should be done towards the latter end of March, care being taken that at no time are they subjected to the full rays of the sun. Moisture should be given in plenty, but the pots or brackets in which the ferns are grown should be provided with sufficient drainage to allow the water to clear away easily, as stagnant moisture at the roots is fatal to them. The majority of ferns may be propagated from the spores, found on the under side of the leaves. When these cases begin to burst the frond should be cut off and carefully wrapped away in clean paper. In the course of a few days, the remainder of the spore cases will have burst, and a very fine dust will have come out of them. This dust should be carefully spread very thinly on the top of a shallow pan or box, containing plenty of drainage and a mixture of loam, sand, and a little peat. The pan should be gently moistened and covered with a sheet of glass, and, in the course of six weeks or so, if the moistening has been regularly attended to, what appears to be a covering of young green moss will show itself on the surface of the soil. This moss is simply a huge collection of tiny ferns, which may be pricked off as soon as they can be handled into other boxes or small pots to develop.

27. LADIES' SLIPPER
Cypripedium

The Care of the Hothouse. The hothouse, which is also known as the "stove," is used for preserving and growing all the choicest exotics which come to us from the tropics. Though the maintenance of a row of tropical houses is an essential feature of large establishments it is often overdone in gardens of moderate size, for, with the exception of the orchids, the flowers of the "stove" are not of great importance so far as their beauty is concerned.

The remarks on the care of a greenhouse given above apply equally to the hothouse, except so far as temperature is concerned. The hothouse should never be allowed to fall below 60° in the winter, and though much less heat than is usually thought necessary will be required in the summer, the thermometer should never fall below 70° at this period. Most exotics are moisture loving plants, and the use of hot-water pipes has a tendency to dry the atmosphere. Moisture must, therefore, be artificially supplied, either by fitting shallow troughs filled with water over the pipes, or else by liberally syringing the floor and wooden stages with water at frequent intervals.

Popular Inhabitants of the Hothouse. The Amazon lily (Eucharis) is a beautiful white lily-like flower, the plants bearing it attaining a height of about 18 in. The flowers are deliciously fragrant, and, as there is always a huge demand for them for bouquets and wreaths, they are well worth growing for market purposes, especially as they can be made to flower practically all the year round. They are grown from bulbs, which should be potted up in a mixture of loam and leaf mould, one bulb to a 5-in. pot. As they will not bear repotting frequently, the nourishment which they would have found in fresh soil must be applied by doses of liquid manure. Under this treatment they will yield two or three crops a year, and the average price of the flowers is about 3s. a dozen.

Though not grown to any large extent in private places, there is an enormous demand for gardenias as cut blooms, both for cheap buttonholes, and also for funeral wreaths. The gardenia is a small bush about 18 in. in height having very deep glossy green leaves, and white flowers with rather a sickly perfume. If potted up in the ordinary mixture of loam and leaf mould with a little red sand, and given plenty of heat and moisture during spring and early summer, they will flower freely through autumn and winter, or they may be had at practically any time by checking the growth. Cuttings stuck into sandy soil in spring root freely, and soon bear flowers, and this is the method generally adopted by market growers. The average price of the cut blooms is 1s. a dozen.

28. CATTLEYAS

Stephanotis [26] is the most widely grown of all the climbing plants in the hothouse. It has white waxy-like flowers of great fragrance, and is best grown in pots plunged into the border, or on a staging, as, if the roots are allowed too much room, the plants run to leaf instead of flower. The ordinary potting mixture suits it admirably, and it is increased from cuttings in the spring.

Ferns in the Hothouse. To avoid repetition, the reader is referred to the ferns of the greenhouse which have been dealt with above for details of culture, these details being equally applicable to the hothouse, the great difference between greenhouse and hothouse ferns being the natural one of temperature. It is more important than ever, however, that in the hothouse the ferns should be well shaded and kept moist—accidental exposure to bright sunshine, especially if the atmosphere happens to be a little dry, will wither them up and kill them

almost immediately. The following ferns are most useful for stove cultivation, and, as they have no English names, it is necessary to set forth their Latin ones in order that the plants may be readily procurable: *Adiantum caudatum, A. farleyense, Asplenium formosum, A. longissimum, Blechnum brasiliense, Davallia elegans, Gymnogramma calomelanos, Polypodium diversifolium, O. pectinatum,* and *Pteris tricolor.*

Orchids. There is no branch of gardening which has been made more bewildering, and more difficult to understand for the young horticulturist, than orchid growing. This is in a great measure due to the fact that new hybrids, the differences in which are indistinguishable even to experts, are being introduced every day. It is appalling to think that at the present time there are over 4500 varieties of orchids, many boasting Latin names of six words in length, ranging from the Odontoglossum for which 1150 guineas was paid in London in March, 1906, down to *Cœlogyne cristata* procurable for a shilling or two. A general knowledge of the requirements of the varieties of the great families of orchids is, however, all that the young gardener can reasonably be expected to possess.

When orchids first arrive in this country from abroad they are naturally in a very dry, shrivelled condition, and can have no better treatment than that recommended by Mr. W. H. White, F.R.H.S., in his excellent work, "The Book of Orchids." "The plants should, within a few days after their arrival, be suspended head downwards in an intermediate temperature in a shady part of the house, and be slightly syringed at least once a day. In a very short time the leaves will have assumed their natural colour, and the stems and old root stumps will commence to emit their new succulent roots. Immediately this is observed the plants should be taken down and placed in as small pots as possible, using the crocks for potting, so as to come up almost to the edge of the pot, covering the whole with good living sphagnum moss, and pressing it down moderately firm."

29. PERENNIAL DELPHINIUMS

The Most Important Genera of Orchids. The Calanthes are winter flowering orchids, the different varieties of which will give a succession of bloom for at least three months. They are grown in pots, half filled with drainage, this being covered with a piece of turf, grass downwards, and the pot filled with loam, sphagnum moss, and silver sand. A little water should be given to the bulbs until the foliage begins to make its appearance, but as the plant grows the quantity should be increased until a copious supply is found needful. This quantity should be gradually decreased as the foliage dies down and the flowers make their appearance.

After flowering the plants should be given rest for a month or two, and the bulbs repotted again in the spring. Some of the Calanthes do not lose their foliage in winter.

Among the largest flowered orchids are Cattleyas [28], purple in one of its many shades being the predominating colour. Many of them will thrive in the coolest part of the hothouse, and they can be grown by planting the pseudo-bulbs in pots, half filled with drainage as recommended for the Calanthe and the remainder a mixture of leaf mould or peat and moss. In their youngest stages they like shade, but as they progress they should be brought into full light and air. After blooming they should be given very little water during the time they are resting. Very closely allied to the Cattleyas are the Lælias, the culture of which is similar in every way, and there are many hybrids between the two families, known as Lælio-Cattleyas. There is a good market demand for Cattleyas. This demand fluctuates a good deal, and the prices change also, but six shillings a dozen blooms is quite an ordinary figure—they sometimes fetch double that price.

One of the easiest grown orchids is Cœlogyne, a variety of which, Cristata, with pure white flowers, is the most useful orchid that can be grown in a small house, or where space is limited, as the flowers are borne so abundantly. The orthodox orchid potting mixture of peat and moss suits the Cœlogynes admirably, and the practice recommended for the Calanthes, of gradually increasing the quantity of water as the plant grows, and decreasing it afterwards, should be carried out.

Cypripediums are more familiarly known as "The Lady's Slipper Orchids" [27], on account of the peculiar pouch which is a prominent feature of the flowers. They are a popular buttonhole flower, and there is hardly a month of the year when one or other of the varieties cannot be had in flower. The mixture of soil already recommended suits them, and they like one of the hottest corners in the house, protection from the direct rays of the sun, and plenty of water all the year round. Care must be taken with the drainage of the pots, however, in order that the water does not remain stagnant about the roots of the orchid, for this is fatal. They usually fetch about 3s. or 4s. per dozen blooms in the market.

Although the Odontoglossum numbers among its varieties the most expensive kinds, there are plenty of others quite within the reach of the very smallest grower of orchids. They may be given the coolest corner of the house; in fact, some of them—notably Crispum and its varieties—will flower in the greenhouse.

An orchid family most remarkable for its long sprays of flowers, which, in the majority of cases, hang downwards, in graceful showers, is Oncidium. Oncidiums will grow almost as readily in ordinary well-decayed leaf mould as in the orchid mixture.

Members of the following families of orchids are the others most generally met with in large collections, and the broad rules of culture laid down will be found sufficient in most instances: Cymbidium, Lycaste, Masdevallia, Maxillaria, Miltonia, Phalænopsis, Stanhopea, and Vanda.

The Cost and Economy of the Small Garden. Whether a garden be large or small, its economical management depends so much on soil, situation, and other circumstances that no hard and fast rule can be laid down to apply equally in all cases. Particularly does this apply to suburban gardens. There are some, notably in the western suburbs of London, attached to houses built on the site of market gardens, the soil in which is naturally good, and where but little in the way of manure is needed every year.

The initial cost of forming such a small garden, too, depends greatly on the condition in which the builder of the house has left it, or, if the house is not a new one, on the horticultural tastes of the previous tenant. Assuming that the ground is not in a very rough state, the following figures will serve as a guide to the initial outlay necessary :

	£	s.	d.
Jobbing gardener, two days weeding, digging, and preparing ground, at 5s. per day	0	10	0
Spade, rake, etc.	0	8	0
Lawn mower	0	14	6
Loam, leaf-mould, potting soil, for improving ..	0	12	6
Manure	0	6	0
Small collection of vegetable seeds	0	2	6
Small collection of bulbs	0	5	0
Small collection of hardy annuals and perennials	0	5	0
Fruit and rose trees and shrubs (say)	1	0	0
	£4	3	6

This figure does not, of course, represent the annual expense, which may in subsequent years be limited to practically the 12s. 6d. comprising the seed and bulb items, as fruit and rose trees rarely require renewing. The item for manure, too, is one which need not recur often, though, in towns, chemical fertilisers must often take the place of horse-manure, which is now difficult to procure.

A greenhouse, with its accompanying heating apparatus, and a frame, constitute a serious item. An efficient greenhouse for a small garden would be one (say, 9 ft. by 6 ft.) costing about £4, and the necessary heating apparatus another £3. A handy sized frame, 8 ft. by 6 ft., costs £2 15s. The prices given are those for the simplest form of house and frame and may be taken as being the lowest at which an effective greenhouse can be established.

Economy in Vegetables and Fruit. The most economical thing that can be grown in any small garden is undoubtedly the scarlet-runner bean. A shillingsworth of these, sown at intervals of a fortnight throughout the spring, will yield sufficient for the needs of a small family during the summer and on into the autumn—that is, assuming that they take their turn with other vegetables. Radishes, lettuce, and mustard-and-cress are most economical vegetables for town-garden culture. Pears thrive in town gardens much more readily than apples, while crops of cherries and plums are usually spoiled by the attacks of birds. Of the bush fruits, the gooseberry is most likely to yield a profitable crop under such conditions.

30. THE BEGONIA

Economy in the flower garden is to be effected by its help in furnishing flowers for indoor decoration and for "buttonhole" purposes. In planting a small garden for economy, it is not at all necessary to put the things in formal rows, as if planting for market purposes. Those flowers which yield large supplies of bloom for cutting purposes should be interspersed with such things as geraniums, calceolaria, lobelia, and the like, which, though not so adapted for filling vases, lend bright colour to the garden generally. Hence, when occasion arises to cut the flowers in the garden with a free hand, the presence of the things just mentioned will conceal the bareness which their absence would only serve to accentuate.

Economical Management of a Large Garden. The economical management of a garden depends almost entirely on the selection of a head gardener, and in this connection it often happens that the best horticulturist is not the man most suited to control a staff economically, and get the maximum amount of produce out of the ground at the minimum expenditure of money.

A young gardener who hopes to rise as high as possible in his profession should be careful not to lose sight of the commercial side of it. The days when an owner of a country seat simply gave orders for a garden beautiful, without counting the cost, are over. Certainly, owners of gardens take much more interest in them than hitherto; and the head gardener who can make the biggest show of bloom at the cheapest rate is the man who will get on.

Economy in labour is one of the most important items in the management of a large garden, and here the individual who calls himself a "head working" gardener will be out of place. In an establishment of any pretensions, where the number of hands employed in the gardens may be anything from twelve to forty, it is a false economy on the part of the head, as a rule, to do any of the manual work himself. It must not be forgotten that, in the majority of gardens, a large section of the staff will be composed of boys and young men, with little or no sense of life's responsibilities, and that the temptation to idle away their time when no watchful eye is upon them is one too great to be resisted. Instead of actually doing things himself, therefore, the head gardener should spend a large portion of his time in seeing that others do them as he would wish. It is a false economy to employ young and comparatively inexperienced men as foremen. Next to the head himself, the well-doing of the garden is in the hands of

these men, and, though it may look well on paper to show a few pounds saving at the end of a year in this part of the wages list by employing low-priced hands, it is of very little use when there is a much bigger item on the other side of the balance-sheet for plants and other things which have been spoiled by careless handling.

Seed-saving. An important item in the management of a large garden is that of seed-saving. Seed of all flowers and vegetables that do well in a garden should be saved every year, and be stored away for sowing the following season. Careful attention to this branch of the garden work will effect a saving of many pounds on the annual seed bill, and the work of picking them over in order to separate the good from the bad is an operation which may readily be carried out during the winter days when there is not so much to be done out of doors, or at any time when inclement weather causes a cessation of operations outside. It is not economy to be constantly introducing novelties into a garden. Changes must, of course, be made from year to year, but thousands of pounds are wasted annually in this country in the purchase of seeds, plants, and bulbs which are boomed as being something new.

It is not too much to say that an economy of 25 per cent. can be effected in the cost of fuel for the hothouses where care is used. Sufficient fuel must, of course, be used to maintain the houses at an adequate temperature, and anything more than that is not only waste as far as the consumption of fuel is concerned, but is not in any way conducive to the welfare of the inhabitants of the greenhouses. It should not be forgotten that coal-dust, damped with a little water, and banked up in the boilers overnight, will preserve an equable temperature in a house till morning, without further attention. This is a far more economical plan than the general one of stoking up overnight with a mixture of coal and coke, which invariably has the effect of raising the house many degrees above its proper temperature during the early hours of the night, and letting it down dangerously by the time the darkest and coldest hour of all arrives—the one preceding dawn.

A watchful eye must be kept on the waste thrown on the rubbish heap. It is a common practice to throw away bulbs that have been forced, plants which have been pulled up in the process of thinning out beds, and other such things. All forced bulbs may be used again in a spot in the reserve garden to furnish a supply of bloom for cutting, and if there is no room for surplus bedding plants, or thinned-out vegetables, they may readily be exchanged or got rid of in other ways.

How to Label. Proper labelling of plants is a far more important factor in the economical management of a garden than is generally imagined. Except in the case of plants which are so generally grown that they cannot fail to be recognised by the merest tyro, it is well to have everything labelled inconspicuously, but at the same time clearly. This is particularly important in gardens where collections of the different species of a genus are made, as, although many of them are very similar in appearance, they require different treatment from each other. In the event of a mistake, therefore, it is easy to see that a lot of valuable plants may be lost through not being labelled at all, or labelled indistinctly. It may be well to state here that the writing on a label should always be commenced at the top end—that is to say, at the part of the label furthest from the point which sticks into the ground. The reason for this is that if the rain and decay tend to make the label illegible, the upper part of it is, in the ordinary course of events, sure to be clearer than that which is close to the ground. If this upper part, therefore, bears the first part of the name of a plant, it is usually easy to guess at the remainder; but if the writing of the label has been started at the lower part, in all probability the last few letters of it only will be legible, and confusion easily follows.

The Need for Tidiness. It need perhaps hardly be said that tidiness and economy go hand in hand in gardening. All such operations as weeding, rolling, mowing, the clipping of hedges, and the hundred and one operations which go to make the garden neat and pleasing to the eye, should be attended to promptly and frequently. It is easy for a lad to remove young weeds, for example, in a very short time when they first make their appearance, but if they are allowed to remain undisturbed for a few days, it is astonishing with what rapidity they will grow, and with what corresponding difficulty and expenditure of labour their removal will be attended. That well-known business maxim, "Do it now," cannot be too rigidly observed in connection with the gardening operations just alluded to if a true economy of time and labour is to be effected. On the other hand, it is well not to be too precipitate with the autumn and winter planting operations, and the carrying out of such schemes as summer bedding. The vagaries of the weather have to be considered here, and premature action in the work may allow a nip of frost to destroy everything, and hence, instead of an economy being effected, a further expense for new plants is incurred.

How to Become a Gardener. Although the oldest profession on earth, gardening is one which is most poorly paid, and the lad who is setting out with the determination to make a fortune should think very deeply before he decides to embrace horticulture as the means to that end. This remark applies more particularly to private gardens. There are plenty of instances on record of nurserymen who have accumulated large fortunes, and, although the market gardener is always pleading poverty, one very rarely sees members of his profession included in the official list of Receiving Orders in Bankruptcy; but in both these businesses there is, of course, a large element of risk. To qualify as a gardener it is necessary to start young. The orthodox way is to secure a berth in some large local private garden or nursery as a boy, at a wage which rarely exceeds 5s. per week. If a lad shows any aptitude the head gardener will be only too glad to push him on, and, in a couple of years time or so, his money will be raised to 7s. or 8s. a week, in addition to living accomodation in the "bothy." This "bothy" is usually an estate house in which the young unmarried gardeners in a private establishment live together, and take it in turns to act the part of housekeeper. If the "improver," as the embryo gardener is called at this stage, lives at home instead of in the "bothy," he is usually paid a shilling or two more per week. As he grows older and gains more experience he develops into a "journeyman." There is no doubt that at this time he gains the bulk of his experience, and if he wishes to learn his profession thoroughly he will do well to change his situation occasionally, and become acquainted with gardens in various parts of the country.

It must be distinctly understood here that the writer does not wish to advise lads and young men to throw up good situations, and go wandering about the

face of the land in and out of work every few weeks. If a gardener is in a situation which seems likely to be a permanent one, and the prospects of promotion are good, he will, of course, stay there if he is sensible. At the same time, experience gained in only one garden cannot be so varied or valuable as that obtained in two or three, where soil, aspect, climate, and dozens of other conditions vary.

Getting to the Top. By the time he is four or five and twenty years of age, the "journeyman" usually considers he has sufficient experience to dub himself a "foreman," and in this capacity he has charge of one part of the garden, under the immediate supervision of the head gardener. The number of foremen employed in a garden varies, but in a place of any pretensions there is usually one for the kitchen garden, one for the flower garden, and a third for the glasshouses and conservatories. His wages are now about £1 per week, and his share in the "bothy;" or 24s. a week, roughly, if he lives outside. The final step from foreman to head gardener usually happens automatically, when the horticulturist is lured into matrimony. He finds that a foreman's wage is not sufficient to support two, and therefore he endeavours to better himself by applying for a situation as head gardener. When he has succeeded in obtaining this he has risen as high as he can ever hope to do in his profession. His emoluments now consist of a salary of 30s. a week, with a cottage to live in rent free, and the privilege of having sufficient of his employer's coal, fruit, and vegetables, for the consumption of himself and family. There are very few gardeners indeed in the United Kingdom who, though they may have charge of places in which thirty or forty men and boys are at work, receive a higher wage than that just mentioned, an income which, in cash and kind, rarely exceeds £150 a year.

Growing for Exhibition. Growing for exhibition at flower-shows is another of the gardener's methods of increasing his income, if his employer does not object. There is hardly a village in the United Kingdom that does not hold its annual flower-show, and many gardeners exhibit at every show within a reasonable radius. The prizes are not large, certainly, ranging as they do from a shilling to a sovereign, but they amount to a considerable aggregate with a consistent exhibitor. The majority of employers are very willing for their gardeners to compete at these flower-shows, and willingly buy exhibition varieties of different plants to facilitate their chance of winning, thinking, as they rightly do, that success at flower-shows is a proof of the skill of their gardener, and an incentive to spur him on to further efforts. At the same time, however, it must be remembered that too much showing is a bad thing. A head gardener who is constantly exhibiting is apt to devote too much attention to his "show" plants, to the detriment of the garden work generally; while his constant absence at the shows themselves, brought about by the necessity of staging and removing his exhibits, is likely to make things get slack in the garden all round. Exhibiting, therefore, should only be done in moderation.

How to Succeed as a Nurseryman and Seedsman. The difference between a florist and a nurseryman and a seedsman is a simple one. The florist is not a producer, but is generally merely an agent for the disposal of goods grown by other people. The nurseryman and seedsman, on the other hand, sells plants and seeds which are the result of his own cultivation and skill. It must not be imagined, however, that nurserymen sell nothing but what they have raised themselves, as large quantities of seeds and bulbs are imported annually, chiefly from France and Holland, to enable them to fill orders which they could not execute from stock of their own raising [see page 4967].

Roughly speaking, nurserymen and seedsmen may be divided into three classes. At least 70 per cent. of them do the bulk of their trade in penny and twopenny packets of seeds, and cheap bedding plants. About 20 per cent. of the remainder have a better class of trade, an important feature of which is the laying out and keeping in order of suburban gardens by contract. The remaining 10 per cent. or thereabouts represent the élite of the trade, who, as a rule, supply only seeds of the finest quality, grown by themselves, and the latest novelties, for which they can command high prices.

How to Start. In normal times undoubtedly the best situation for a nurseryman and seedsman who contemplates starting in business is in the outer suburbs of London or one of the other great cities. In such a situation he will be able to grow plants and produce seeds, free from the taint of city smoke, though, at the same time, they will be hardy enough to withstand the rigours of town life. A large portion of his trade will be purely local, although the postal department of a nurseryman's trade is one which ought never to be neglected. Naturally, the greater portion of the stock of a seedsman who caters for the million will have to be purchased by him from the wholesale houses in bulk, and made up and retailed in small quantities. Much of the success of the retailer will depend on the quality of the seed he thus dispenses. If he is careful to deal with wholesale firms of high standing, our young nurseryman is, at all events, sure of giving satisfaction to his customers.

A certain amount of seed of such things as calceolaria, petunia, lobelia, and other popular plants should be sown very early in the year in heat, with a twofold purpose in view. Some of the plants so raised will be required in the late days of spring and early summer, either for selling to chance customers, or for the purpose of fulfilling any contracts to keep gardens and window-boxes in order which the nurseryman may have been fortunate enough to secure. Keeping gardens in order by contract is a very profitable branch of a nurseryman's business, and a good trade may often be done in this direction by a local canvass of likely houses during the months of April and May.

Mail Order Business. If this branch of his industry should at first not come up to his expectations, there is another channel through which the nurseryman can dispose of any plants he may have on hand. This is by means of advertisements in the horticultural journals, bearing always in mind the fact that the nurseryman should draw up his advertisement with a view to disposing of what he will have ready for sale in a fortnight or three weeks' time. Most horticultural journals go to press at least a week in advance, and the consequence is that plants, which may be ready for disposal at the moment of drawing up the advertisement, will be past their best time for transplanting when the announcement is made public, and orders begin to come in. Intelligent anticipation will do much to assist in this branch of the business.

Silk Hand Dyeing. Machinery for Dyeing. Yarn and Warp Dyeing. Jiggers. Padding Machines. Washing and Drying. Dyeing of Special Non-textile Materials.

DYEING MACHINERY

MACHINERY driven by power came into use in dyeing practically with the artificial dyes and the subsequent enormous expansion of the trade. When the dyer had to deal with small quantities of goods—a few bundles of yarn or a small piece or two of cloth—he was content to use vats sunk in the level of the dyehouse floor, as in the old and still-used process of indigo dyeing, and with tubs and kettles, working the goods with his hand, or, if the heat would not allow this, with rakes or forks or with a long, crutch-like stick known as a "jigger." The resemblance of a billiard-rest to this article has given us a familiar slang-word.

Hand Dyeing. Dyeing by hand is still largely practised; it is the rule in treating delicate fabrics such as silk. In machine dyeing complete and easy solubility of the dye-stuff and level dyeing properties are necessary; in hand dyeing any drawbacks in these respects can be more easily overcome. Fabrics are simply "worked" in dye-kettles by means of a pole or jigger, and yarn is dyed in a vat. The ordinary form this takes is simply a strong, oblong box, fitted with a steam-pipe below a perforated false bottom. The steam may be either blown in direct, or a closed steam-coil may be used. The latter is usually preferable.

In dyeing hanks or skeins, the hanks are strung in festoons on sticks. These are ordinarily straight, but in some cases—in using the sulphur dyes, for instance—they are bent so as to keep the yarn constantly under the surface of the bath. The hanks are dipped into the bath, raised and lowered in the liquor a few times, and then left in the bath, with the ends of the stick resting on the edges of the vat. The next stickful is then introduced in the same way; and when all have been entered, leaving a space between each to prevent entanglement, the first is lifted by two men, standing one at each side of the vat. One of them thrusts a stick through the hanks, and when the other has grasped his end they lift the hanks so that they are well turned on the stick, and the part of the yarn that was resting on it is now in the bath. The others are treated in the same way, and the yarn is said to have had "one turn." The men go on to give "three turns" or more, according to their judgment or instructions.

Foam Dyeing. This is a system of treatment in which the material is dyed not in the liquor of the dye-bath, but in the froth arising from it produced by the action of jets of steam. It has been used very successfully for cotton fabrics and for silk. The diagram [1] merely shows the principle of the apparatus, which, it will be gathered, consists of a vat with a grid at A, over which the goods to be dyed are packed. The dye-bath, B, must not rise above the level shown at D, as only the froth must act upon the goods. A perforated pipe, C, blows in steam, which sets up a strong foam, the concentrated dye-bath needing only the addition of a little Turkey-red oil. The bursting bubbles have extraordinary penetrativeness, and the material can be closely packed down upon the grid A. With a closed-in apparatus on this principle the dyeing of cops and cross spools has been successfully effected.

The Wince. The dye-beck with a wince represents the simplest form of machinery in the dyehouse. A skeleton roller is mounted on a wooden box capable of containing 250 to 300 gallons of water, and this is the wince, frequently pronounced and even written "wench," of the Yorkshire dyehouses. The cloth is stitched in an endless band, passed over the wince and round guide rollers in the dye-beck. It is then run through the bath either by power or by hand until it is evenly dyed to shade. It can be mordanted and washed in the same beck. This apparatus is especially useful in woollen piece-dyeing where the goods must be treated in long baths—*i.e.*, in plenty of liquor, which must be kept boiling.

For heavy cotton goods a rather more complicated machine known as a jig wince is useful. This may also be used for warp dyeing and for washing after dyeing in the jigger. The cloth is not drawn immediately through the bath, but is allowed to lie in folds, in order to give the dye plenty of time to act on it.

Dyehouse Machinery. Broadly speaking, the form of machine used differs little with the kind of fibre under treatment, but widely with the state of manufacture. In other words, a cop of yarn cannot be dyed like a piece of cloth, nor will muslin stand the treatment of strong cloth or felt. The careful manipulation required for silk makes it necessary to dye it by hand or with a simple form of machinery not liable to damage the fibre. The quantities ordinarily dealt with, moreover, allow most of the dyeing to be done by hand in wooden dye-vats, or even in earthenware or porcelain vessels. It is dyed in the form of yarn or cloth; and in a few of the largest silk dyehouses some of the simpler forms of machines used for dyeing cotton in the hank and in the piece have been adopted, in order to handle quantities rapidly.

In one form of special machine for silk yarn the hanks are placed over a reel, free at one end, so that they may be readily put on and taken off and run through a dye-vat, the reel or rollers revolving so as to pass every part of the hank continuously through the dye liquor. In another form, the hanks are hung on a pole, or between two poles, and carried through the dye-bath with a revolving action, to ensure even dyeing. As regards pieces, the wince arrangement already described is used, or a simple dye-jig, which will be described later.

Wool and Cotton Dyeing. Wool is dyed as the loose raw material, but the bulk of it is treated in the form of slubbing or in the woven state. Cotton is dyed in the raw state and in every stage of manufacture, as sliver, rovings, cops, or cross spools, in the hank, in the warp, and in the woven fabric. For each of these forms of material a multiplicity of special machinery has been devised; and in this course it will be requisite to confine ourselves to typical machinery, and in most cases we endeavour to show the principle of the

action rather than the actual machines. It may be here stated, without fear of contradiction, that British engineers are pre-eminent in this branch.

Loose Fibre. The advantage of using coloured weft cops, obviating the necessity of any subsequent reeling before the introduction into the shuttles, is evident in the manufacture of fancy and parti-coloured fabrics. It is obvious that one way out of the difficulty of dyeing tightly wound cops through and through is to dye the wool or cotton before spinning. Technical difficulties, however, for long stood in the way. It was not easy to ensure sufficiently even penetration to get uniform results; wool was liable to felt, and cotton lost its "nature," as the spinners say, so that in either case spinning was difficult and possibly imperfect. These defects have been largely remedied by the recent use of Turkey-red oil or the polysulful oils and soaps introduced by a Lyons chemist, M. Juillard. These assist penetration and preserve the nature of the raw material.

The Klauder-Weldon machine has been used for loose cotton, but it is unsuitable for wool. It is very similar to the modern washing-machine in the steam laundry; a drum of copper netting containing the loose material revolves in a heated dye-bath until the dyeing is effected, and it is obvious that by changing the baths, the same machine may be used for bleaching, mordanting, or washing. A much-used machine for loose material is that of Obermaier, manufactured by Messrs Mather & Platt. In this the loose material is stationary, the liquor being forced through it, a point particularly important in the case of wool as felting is avoided. Part only of the machine is shown in the diagram [5]. The circulation of the liquor in the direction of the arrows is effected by a centrifugal pump, A.

Sliver or Slubbing. The advantages of the dyed cop are better obtained by dyeing what the spinner calls "preparation"—that is to say, the cotton in some state of preparation for the spindles. After it has been opened and scutched, a great amount of dirt has been removed which interferes with the purity of shade when raw cotton is dyed; and if it has been carded, the injury done to the cards by the mordant is obviated.

A fresh difficulty, however, arises. The woollen slubbing or cotton sliver must not be broken, and even cotton rovings would not stand the treatment which is allowable with raw cotton. The Obermaier machine, in which the material is left undisturbed, is also the standard apparatus for the purpose. The movable copper cylinder, B, can be lifted out of the dye-vat by means of the hook, C, by means of a travelling crane. The vat is heated by steam. When the cylinder, which is varied in formation somewhat, according to the material to be dyed, is packed with the goods, it is lowered into the vat, steam is turned on, and the centrifugal pump is set in action. This circulates the dye liquor in the vat through the goods by means of the perforated centre tube, and back into the vat again. When the desired shade is obtained the cylinder is lifted, and goods are removed and hydro-extracted. They may be washed in the same receptacle or dried in it by means of a current of hot air if desired.

Cop Dyeing. The cop is yarn as it is taken from the spindle. It is very compact, and consequently very difficult to dye. The advent of the direct cotton-dyeing colours has, however, assisted the cop dyer, as they have great solubility and do not require mordants, which form a solid lake on the fibre and interfere with the penetration of the inner layers of the cop. In dyeing, the cop is mounted on a hollow perforated spindle, and placed in a machine which forces or sucks the liquor completely through the yarn, or both alternately. Weft cops for dyeing or bleaching are not mounted on the narrow paper tubes ordinarily employed in spinning weft (paper bottoms), but the first layers of yarn on the spindle are stiffened with a little paste (paste bottoms). As in dyeing loose material, the main difficulty is the question of even penetration. The liquor has the natural tendency to take the line of least resistance, with the result of want of uniformity of shade throughout the cop. Penetration is assisted by the addition of spirits of wine or a sulphonated oil to the bath.

The principle of a cop-dyeing machine is shown in the figure [4]. Perforated spindles are arranged round the surface of a cylinder, as shown in the detail, B, and this is immersed in a dye-bath. The tube, D, is connected with an air compressor, and E with a suction pump. The action of these drives the dye liquor, via the tube, H, through the cylinder and the cops on it. When the vat is sufficiently full, a vacuum is created in C, and the action is reversed. The liquor passes back through the cops into the cylinder, and is drawn back into C by the tube, F. This alternate action is continued until the cops are thoroughly dyed.

Cheeses (small warps resembling a single Gloucester cheese) and spools (yarn wound, for instance, by means of a split drum) are dyed and bleached in the same form of machine, with slightly different mounting arrangements for the cheese or spool. As the yarn is less tightly wound, it is easier to get level shades throughout than in cop dyeing.

Beam Dyeing. This is one of the latest developments. Yarn is now dyed on perforated beams. The dye liquor is forced through the material by means of pumps, much after the manner of dyeing cheese warps. The advantage is that a back beam of large dimensions can be dyed ready to serve as warp in the loom. The principle of the machine used is shown in the illustration of the cop-dyeing machine, the perforated beam replacing the cylinder, A.

Hank or Skein Dyeing. The hank is the reeled yarn, and presents the form that is familiar to the public in skeins of thread. It requires very simple machinery; in fact, in dyeing yarn in hanks, the only thing to be avoided is the entanglement of the yarn. The simplest form of apparatus has already been described under hand dyeing, and is still very much used, especially when many small lots of yarn have to be dyed different colours.

A typical form of yarn-dyeing machine is the Klauder-Weldon. In this the yarns are arranged on a pair of rods suspended between two revolving discs, which carry the yarn through the dye liquor contained in a semi-cylindrical vat. The hanks are steadily carried through the dye liquor, and, there being no motion of the hanks, there is no chance of any entanglement. The machine works very successfully, is simple in operation, not liable to get out of order, is capable of dealing with large quantities of yarns, and is economical of dyestuffs.

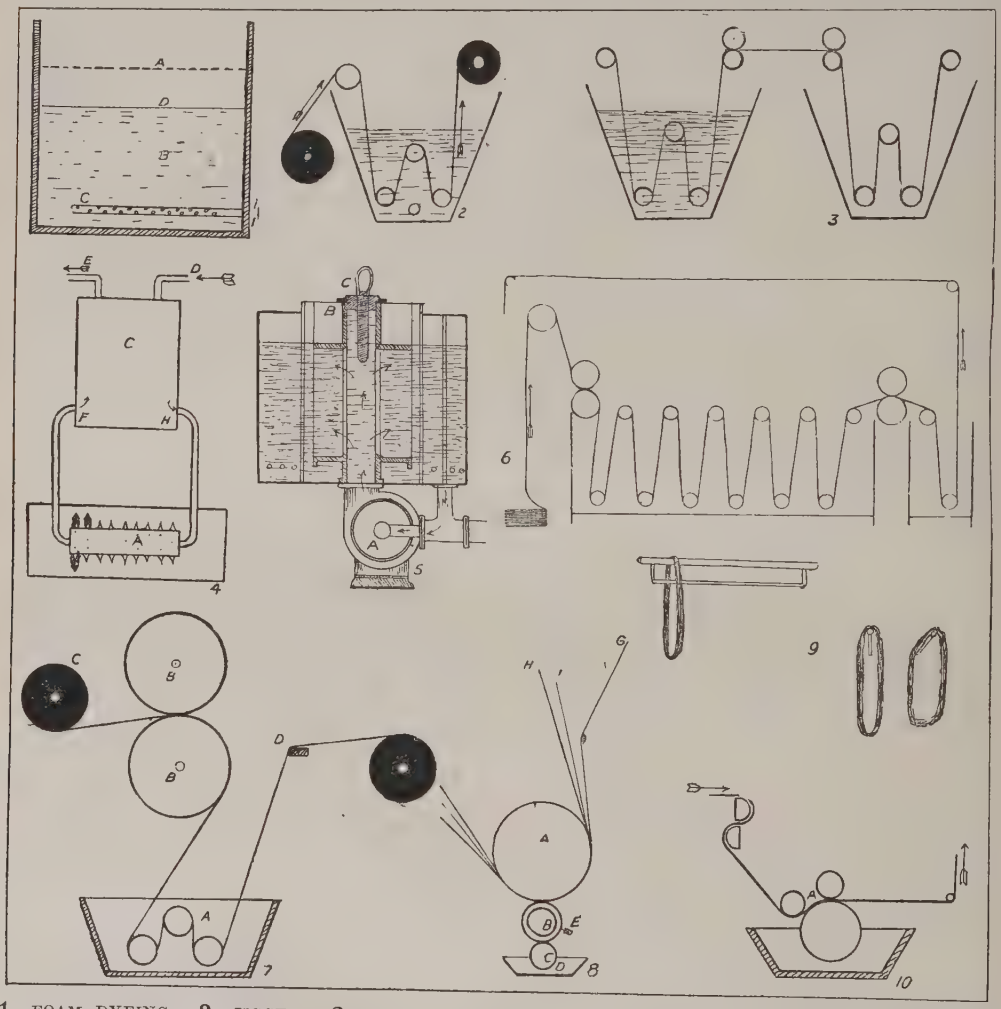
A very ingenious yarn-dyeing machine is that of Corron. In this a rectangular dye-tank is provided, and over it a travelling arrangement which,

in passing from one end of the tank to the other, picks up the rods full of yarn, turns them over, and drops them back again. The simple arrangement by which the hanks of yarn are turned over in the dye-bath is shown in the diagrams [9]. Hand-work is closely imitated by this machine.

A perfect hank-dyeing machine would seem to be one in which either the hanks are kept still and the liquor is caused to circulate through them, or one in which the hanks are carried through the dye liquor, but must not, while doing so, be subjected to any rapid movement tending to bring about entanglement of the hanks one with another. The hanks should not be tightly stretched, but hang somewhat loosely, because then the dye liquors can more thoroughly penetrate to every fibre of the hank.

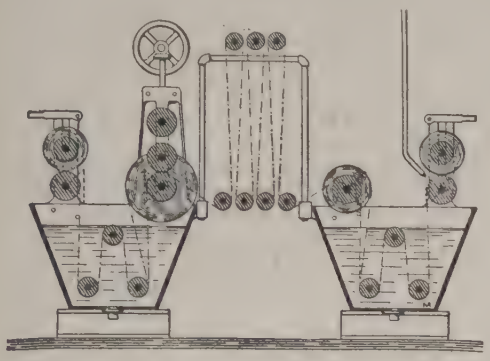
Warp Dyeing. Warps are collections of yarns in long lengths, ready for the loom. They come into the dyer's hands in several forms, but usually in large balls of about 12 in. in diameter (ball warps). In the process of dyeing, the threads must not be entangled, otherwise they will not lie straight on the loom or pass freely through the eyes of the healds, and so breakages will occur that are undesirable.

The usual plan of warp dyeing is to have a vat as in the diagram [6], with a number of guide rollers at the top and bottom, and to pass the warp round these rollers, and thus, as it passes through from the first to the last roller of the set, it travels several times through the liquor. By running the warp backwards and forwards, giving it several "ends," it can be effectually dyed. This method works well; the threads of the warps can be kept level and straight, and the dyeing is uniform. It necessitates the unwinding of the ball of warp in the first instance on to a winding roller, and, when dyed, rewinding back again into the ball form, although, if the dyer be also the manufacturer, this rewinding may be omitted, and the warp wound ready for use on the warp beam.



1. FOAM DYEING 2. JIGGER 3. PAIR OF JIGGERS 4. COP-DYEING MACHINE 5. OBERMAIER MACHINE 6. WARP-DYEING MACHINE 7. PADDING MACHINE 8. SLOP PADDING MACHINE 9. HANK-DYEING: CORRON METHOD 10. PADDING ANILINE BLACK

The problem comes up whether the warp could be dyed in the ball form, with all the threads in position and undisturbed. If it could be done efficiently, and the colour be level throughout, then this method would save the trouble of unwinding and rewinding the warp. Now, simple immersion of the ball of warp into the dye liquor will not do, for it will not come up of a level shade. The dye liquors are found not to penetrate right



11. PAIR OF JIGGERS WITH AIRING FRAME

into the centre of the ball warp, and so the outside gets dyed the deepest shade while the centre either does not get dyed at all or only a pale tint. This want of penetration is caused by the tightness with which the ball is wound acting as a resist to the penetrative capacity of the liquor; and, secondly, there is no doubt that the air enclosed in the interstices of the warp in the interior of the ball, prevents the liquor from getting into the central parts, because the liquor in turn prevents it getting away with sufficient freedom. What is wanted in order to dye a ball warp is some means of forcing the dye liquor right to the centre. Winding the warp into an Obermaier apparatus would do very well, and perfect results can be obtained, but, as with the warp-dyeing machine, this necessitates unwinding and rewinding of the balls. Placing the warp into a closed chamber and circulating the dye liquor through is an improvement, but even then there is much chance of the centre being paler than the outer portions. A better plan would be to wind the ball on a spindle in the first instance, and then to put the ball on a hollow perforated spindle through which the liquor can be forced. In this way a modified Obermaier can be used, and good results attained.

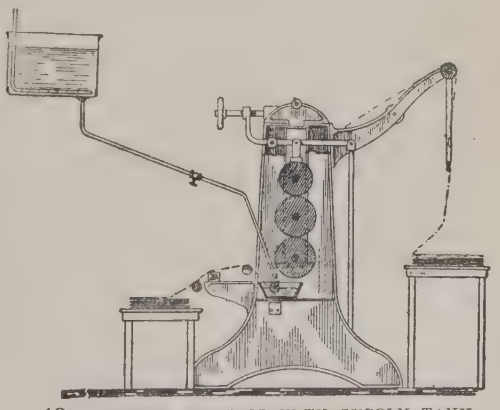
Jigger Dyeing Machine. The action of this simple "dye jig" is sufficiently explained in the diagram [2]. The cloth is wound on a roller round the guide rollers shown at the bottom of the vat, and round a second roller. This is revolved, drawing the cloth through the bath and winding it. When all the cloth wound on it has had "one end," the action is reversed, and it is given as many ends as necessary. Then it is "batched" on to the larger roller shown to the left of the diagram. This "batching roller" is then removed for subsequent processes—washing, drying, etc. The reversal of the motion of the rollers is automatic, and there are simple arrangements for regulating the tension of the cloth. In dyeing calico and unions in the full width, this is perhaps the most universally used machine. The jigger is used for dark shades, as strong short baths can be used.

When heavy drills or thick cloths generally are under treatment, the use of the squeezing rollers is advisable, as they effectively drive the liquor into the goods. Only one batching roller is shown, but a similar roller can be mounted on any of the outstretched arms, either to the right or left of the vat. For the purpose of attaching the cloth to the rollers, it is a common practice to sew a piece of cloth tightly round each roller, leaving a loose end to which the piece can be attached. In the place of the single guide roller shown over the vat at the left of the figure, squeezing rollers are often provided. These press the excess liquor back into the dye-bath.

Jiggers are very often run in pairs, the diagram [3] showing a pair with squeezing rollers. The right-hand vat is empty, this arrangement being sometimes adopted for sulphur colours; the goods are dyed in the first vat and oxidised in the second. It is obvious, also, that the second vat can be used for rinsing; or sometimes it is convenient to carry out the dyeing operation in both jiggers, running the cloth through them continuously. For the sulphur dyes and vat colour an airing frame [**11**] is mounted between the jiggers, and squeezing rollers are necessary.

There are many forms of jiggers for various purposes. The most modern is, naturally, for the vat colours. In this the goods are wound backwards and forwards between two rollers under the surface of the liquor.

Spiral Dyeing Machine. In this machine the cloth is not in tension, and may be dyed in separate pieces between pegs on the top roller, or stitched together "on the endless system." The pieces on the continuous band traverse the *beck* in a spiral, a loop at the bottom keeping the cloth fairly slack. This slack loop allows the cloth to remain longer in the liquor and promotes even dyeing. The machine is much used in dyeing on a large scale, as the beck can be made of any

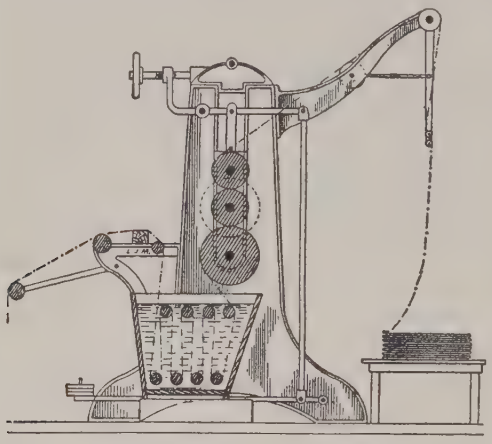


12. PADDING MACHINE WITH SUPPLY TANK

practicable length, capable, say, of dealing with thirty pieces at a time.

Circular Back Machine. This is a form of the dye-beck and wince for cloth already described. It has a small cylinder engine attached, and the wince is driven by a reversible eccentric, so that the cloth can be run through the bath either way as desired. This is principally used in Leeds and Huddersfield for West of England cloths.

Hawking Machine. This is used in dyeing when it is necessary to keep the cloth under the surface of the liquor throughout the operation to guard it from exposure to the air. It consists of a series of guide rollers arranged in the dye-vat so that they are completely covered with the fabric, which is drawn continuously at full width through



13. JIGGER PADDING MACHINE

the bath by means of a pair of rollers, also, of course, under the surface of the liquor.

Padding. As the name implies, this is a rapid method of dyeing cloth, suitable only for light shades. When one side only of the cloth is covered, this is called "slop-padding," a style of work very suitable for discharge effects. The ordinary padding machine consists of a trough containing guide rollers, and with a pair of squeezing rollers above it. The cloth passes through the dye liquor in the trough, round the guide rollers, between the squeezing rollers, and away.

In the two-roller padding machine shown in the diagram [**7**], the vat, A, contains the dye liquor, which is usually thickened with starch and gum tragacanth. The block, D, is provided to give a little drag on the cloth, which passes under and over the guide roller in the vat, through the nip of the squeeze rollers, B, and is then batched at C. In a three-roller machine [**12**], the cloth passes through the bath, then through the nip of the two lower rollers, through the bath again, and through the nip of the two upper rollers. The amount of colour taken by the cloth depends not only upon the strength of the dye-bath but also upon the pressure of the squeeze rollers.

In "slop-padding," the piece passes as shown [**8**] round the large iron roller, A, which presses against the copper roller, B. The roller B is fed by a wooden roller, C, running in the thickened colour in the box, D. This is actually a printing process, and the cloth does not run through the dye-bath. The printing roller may be engraved with fine lines to enable it to take up more or less colour according to the depth, and, as in the printing machine, it is provided with a doctor, E, to scrape off the excess colour. Between the cloth, G, and the iron roller A is a blanket, the elasticity of which enables the cloth to take the colour. This is marked H, and a back cloth, I, is often provided, to prevent the blanket from being soiled. In aniline black dyeing, and in some other styles, the cloth is often printed with a reserve, and in this case a slop-padding machine is used, as shown in the diagram [**10**]. The goods are guided between two rollers, with the printing side pressing against the lower one, which is of much larger diameter than the upper roller and turns in the bath. The roller A keeps the cloth in touch for a few inches with the colour, to enable the fabric to take up sufficient dye. The reserve prevents the dye from going on to places where it is printed, and thus produces a pattern, in white or in colours as the case may be. Instead of a blanket, the penetration is regulated by the pressure of the upper roller, which is covered with indiarubber.

The jigger padding machine [**13**] combines the advantages of dyeing and padding, giving very thorough penetration.

Continuous Dyeing Machine. As shown in the diagram [**14**], this is usually made with four or five compartments, each with its own pair of squeezing rollers, the upper one of each pair being coated with rubber. The first compartment is for wetting out, the others for dyeing, rinsing, and after-treatment, as required. As a rule the dye and other liquors are supplied from overhead tanks; and when the speed of the machine and the rate of the inflow is fixed, the process is practically continuous, and allows a large output of work with a minimum amount of labour and attention. This machine is also used for *diazotising* and developing, but in this case three compartments are sufficient, as shown in the diagram [**15**]. The pieces previously dyed and washed on another machine are transported to this apparatus, the first box of which contains the nitrite of soda and hydrochloric acid for diazotising; the second box, B, the rinsing water, slightly acidulated from the hydrochloric acid tank, and the third, C, contains the developer. Each compartment is separated, as shown, by heavy squeezing rollers.

Steaming. After dyeing, some colours—for instance, aniline black, Turkey-red, and many of the alizarines—require steaming under pressure to develop and brighten the colour. Messrs. Mather & Platt's "Cottage," steamer is universally used. It is a strong wrought-iron cylinder, one end of which gives access by means of a sliding door with counterweights. It is used either for yarn or cloth, and the position of the goods round the rollers can be varied from time to time by moving the exterior handle.

Any pressure up to 30 lb. per square inch (roughly, two atmospheres) may be applied.

Soaping and Washing Machine. This continuous open-width machine can be made with any number of cisterns from one to twelve. In its most general application it is used as a combined raising or fixing, soaping and washing machine. Besides this use, it can also be employed with advantage for "cutting" indigo-dyed goods, developing naphthol colours, or chroming aniline blacks.

A medium-sized range, with six cisterns, can be used as follows: (1) raising or emetic cistern; (2) washing cistern; (3 and 4) two soaping cisterns; (5) clean soap cistern; (6) washing cistern with heavy squeezing bowls. With the exception of the raising cistern, all the cisterns are fitted with beaters of non-corrodible metal, placed below the surface of the liquor and between the vertical laps of cloth. These beaters are driven independently at a high speed, whatever may be the speed of the

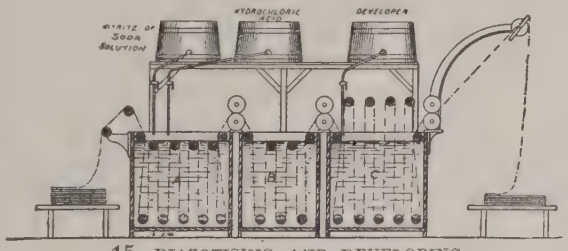
cloth through the range, and they dash the liquor with great force upon both sides of the cloth, thus thoroughly cleansing it and loosening and removing any thickening matter which may have been used in the colours, and any by-products from the use of mordants or discharges, while not the slightest injury is done even to the most delicate fabrics.

Wringing, Squeezing, and Hydro-extracting. The wringing post has a hook or sort of short perch upon which yarn can be twisted by hand to drive off excess of moisture. In squeezing, rollers are provided upon many machines, through which the yarn or cloth passes, and the excess liquor runs back into the bath. By taking advantage of the law of centrifugal force, much more moisture can be driven off by means of a hydro-extractor. In wringing, less than 50 per cent. of moisture is removed; by squeezing, about 70 per cent.; whereas over 80 per cent. is driven off by "whizzing," as it is familiarly termed. The hydro-extractor is now largely used in the steam laundry, and the economy of this preliminary drying process will be apparent.

14. CONTINUOUS DYEING

The hydro-extractor is a perforated metal basket, mounted in an outer case, so that it can be revolved at a high rate of speed. The goods are packed into the inner basket, and the machine is set in motion, revolving at the rate of 1500 revolutions per minute. The water expressed by the powerful centrifugal force is thrown into the case, and escapes by means of a drain pipe. Hydro-extractors vary in detail according to the special use to which they are put.

Washing. Thorough washing is one of the most important processes in the dyehouse, and it is one that might have to be repeated several times in the stages through which the goods pass before they are ready for the market. All surplus mordant must be washed off before dyeing, otherwise it forms insoluble lakes in the dye-bath, wasting colour and leading to spotty dyeing. As a rule, but not always, the goods must be washed after dyeing, to clear the fibre and to freshen the colour. As we have seen, the mordanting, dyeing, and washing may proceed as a continuous operation in a machine with several "holes," or the beck, or jigger, may be cleared of liquor and filled with clean water. Special machinery, however, is useful in some cases.



15. DIAZOTISING AND DEVELOPING

Drying Cylinders. The machine for drying both sides of the cloth takes the form of a number of cylinders [16], heated by steam. These were all formerly, and are still as a rule, made of tin-plates, and hence are commonly known to the finisher as "tins." The cylinders are heated by steam passing through their hollow axles, and revolve as the cloth passes over them, thus constantly bringing up a fresh heating surface. In diagram 16 the cylinders are shown in an horizontal position, but they are often mounted vertically.

Steaming and Ageing. The continuous steaming and ageing machine is referred to in all technical literature as the "Mather & Platt," a sufficient testimony to its universal application. It is a chamber fitted with a number of copper rollers to guide the piece while passing through. It is used for a large number of colours, which are developed by steaming, and for ageing (*i.e.*, oxidising) aniline black, the steam acting as an oxidising agent. In the latest machines two or more "runs" of cloth can pass abreast. This enables a chamber of half the height or length of those constructed for a single run of pieces to turn out the same quantity of cloth.

NON-TEXTILE DYEING

A very large number of articles are coloured artificially for one purpose or another. Leather, paper, straw, and feathers are the most important of these. Volumes have been devoted to the many methods of dyeing these materials, and in the short space at our disposal in this course it will be possible only to touch on the broad principles of the art.

Leather. In leather dyeing the effect produced depends upon three perfectly distinct causes. One of these is the mechanical inclusion of dyestuff in the pores of the material—that is, its imprisonment in interstices which nothing can reach except a liquid. In these spaces the dye is deposited in the solid form by the evaporation of the solvent, and is protected from external agencies by the surrounding walls of leather.

The second cause is the chemical combination of the dye with the leather material itself. Like wool and other animal substances, leather has a strong affinity for certain dyes.

The third is the production of a lake by combining the action of the dye solution on the leather with that of a mordant. When tannin or chrome is used in preparing the leather from the raw hide, it plays a double part by acting as a mordant as well.

The choice of dyes depends largely upon the manner in which the hide has been prepared. There are three principal methods. One is with inorganic salts, especially with those of chromium and iron; a second is with tannin, while the third is chamoising, or preparing the skin with an animal fat, such as fish oil. It is easy to see that if these methods are combined, as is often the case, the difficulties of the dyer are much increased.

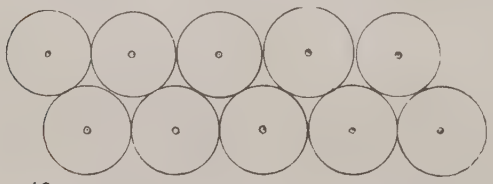
Dyeing Varieties of Leather. The main principles underlying the dyeing of the three sorts

of leather may be stated briefly. With oak-bark leather, or other leather tanned by natural tans, attention must be paid to the natural affinity for dyes of the leather itself, and the utilisation as a mordant of the free tannin present in excess so as to economise the use of the other mordants. With chrome leather regard must be had to the lake-forming properties of the metallic oxides present.

In the case of chamois leather we have to rely either upon the chemical affinity of the dye for leather or upon mordanting, or to take advantage of both. It is in many cases necessary to remove the superfluous grease before dyeing, as its presence not only hinders the absorption into the pores, but forms an insulating layer preventing due contact between the fibre and the chemicals.

The dyer of bark-tanned leather is dependent entirely upon the previous treatment. It is quite impossible to dye properly a badly tanned leather. The flesh side must be perfect, or no care will prevent the formation of streaks and spots. The tan must also be uniformly distributed through the entire mass of the leather, or the same results will ensue. When a leather has been dyed which is nearly but not quite faultless in these respects, it may seem unexceptionable on leaving the dyer's hands, but it will be sure to develop inequalities of shade after exposure to atmospheric influences.

Dyes for Leather. Tan leather is dyed with coal-tar dyes, with colour lakes, and also with direct vegetable and mineral colouring matters.



16. ARRANGEMENT OF DRYING CYLINDERS

Nine-tenths of the leather dyed is dyed with coal-tar dyes. Genuine Russia leather is dyed black with logwood on a mordant of alum and copperas, and red with sanders wood on an alum mordant. Other colours are dyed with anilines. Most dyers use logwood for black, the full black being secured with a little fustic. Cutch, which combines tannin and dye, is largely used.

In dyeing with coal-tar colours which require a mordant, lactic acid, bichromate, tartar-emetic, yellow prussiate, and the sulphates of alumina, iron, and copper are those chiefly employed. Most of the coal-tar colours used are, however, substantive dyes, and the shade is regulated by the strength of the bath. Tannin-dyed leathers take neutral or basic dyes without a mordant, and acid dyes if mordanted. Alum-tanned and chrome-tanned leather take acid dyes substantively.

The great object to be gained on tanned leather used for bootmaking and in upholstery is fastness to light. In the case of boots, the dye is, or ought to be, protected from weather by the usual dressings. Hence the dyer picks such dyes as are fast to light, and, when possible, those which require no mordanting. It has been found that if bark-tanned leather is painted over with an ammoniacal solution of an alizarine, and then mordanted with alum or iron, a good colour can be got without much heating, which would tender the leather. It is found that the use of iron or aluminium salts as basic as possible is desirable ; the neutral salts do not easily form lakes with alizarines, with the result that a good deal of the dyestuff is wasted. Basic nitrate of iron appears to answer every requirement in this connection, and is effective at hand-heat.

Dyeing Chrome Leather. Chrome leather dyes directly with great ease with any acid coal-tar dye, the only precaution necessary being that the leather should be thoroughly wetted before entering the dye-bath. For neutral or basic aniline dyes, a previous mordanting with sumach is necessary for light shades. For darker shades the sumach is replaced with fustic, and for the darkest with a mixture of fustic and logwood. Alizarine dyes answer very well for chrome leather, because the material stands the high temperature required, which bark-tanned leather will not do, except by the special treatment above mentioned. Chrome is the best mordant for alizarines generally. Lactic acid is a very useful assistant mordant for chrome leather if specially fast shades are required. It should be pure, however, as impurities are extremely apt to produce unlevel shades, especially with dyewoods or sumach.

Chamois Leather. Chamois leather can be mechanically coloured by rubbing in any desired pigment. If, however, it is to be dyed with a substantive or adjective coal-tar dye, it is freed from fat by washing, and then dyed exactly in the same way as tanned leather. For light shades, a preliminary bleaching is usually necessary, and this is generally done with sulphurous acid and permanganate of potash. When the leather has become a full brown by impregnation in the permanganate solution, it is rinsed and put into sulphurous acid solution just sufficiently long to remove the precipitated oxide of manganese. It is then rinsed and dried. Sulphurous acid alone cannot be used, as it tenders the leather and does not bleach it thoroughly.

Dyeing Paper. The mineral colours are largely used in dyeing paper. While the earliest procedure was to amalgamate the dye with the size, and thus to apply it to the paper after manufacture, it has now been found much better to dye the pulp, thereby securing the colouring of the paper through its whole thickness. This operation is by no means so difficult as cotton or wool dyeing, inasmuch as it is only necessary that the colour should not rub off, should be fast to light, and should not injure the cohesion of the paper. Hence the papermaker has a very large choice of dyes; and as the mineral dyes are especially cheap and fast to light, his preference for them is easy to understand, although they act prejudicially upon the durability.

The most usually employed of these mineral dyes are ochre, chrome yellow and chrome red, prussian blue, ultramarine, graphite, and lampblack. These, very finely ground, must be added to the pulp, either in a pulp mill or in a vat provided with a stirrer. The stirrer is necessary with heavy substances such as red-lead, litharge, chrome yellow, and manganese, on account of their great tendency to settle to the bottom of the vat.

Some few mineral dyes can be actually made in the pulp, as, for example, prussian blue, by adding to the pulp ferric chloride and potassic ferrocyanide, ochre by adding ferric chloride or ferrous sulphate and milk of lime. By generating the dye in the pulp itself, it is got in a finer state of division than is attainable by grinding, so that the colours are brighter and more uniform.

Mineral Dyes for Paper. It is, perhaps, unnecessary to say that the fineness of the tints depends also upon the constitution of the pulp, and for pure lively colours the latter must be carefully chosen or previously bleached.

Yellows and Oranges. Chrome yellow, which is absolutely fast to light, is the best yellow. By adding reds to this, any desired orange hue can be obtained. Ochre is best generated in the pulp, on account of the labour required to grind and levigate it properly.

Blues. Turnbull's and prussian blues are readily generated in the pulp, and are even to this day unsurpassed by any coal-tar colours. In using ultramarine, any excess of acid or of sulphate of alumina must be absent from the pulp, as both destroy the colour.

Greens. Seventeen parts of chrome yellow and one of prussian blue gives an almost pure green. Different shades are, of course, procured by altering these proportions.

Blacks. Of special importance for grey shades of black are lampblack and graphite.

Vegetable Dyes for Paper. As regards vegetable dyes, logwood, fustic, and cutch are chiefly used, on account of their cheapness and comparative fastness to light. Logwood is used either for darkening other dyes or for making a lake of a dirty violet hue by boiling the logwood extract with tin salt. This lake is used with iron salts for grey and black papers.

Coal-tar Dyes for Paper. The coal-tar colours are mostly soluble in water. If they were used for paper in the same way as for textiles, most of the dye would run off in the waste water from the machine wires. It is therefore generally necessary to precipitate the dye in an insoluble state upon the fibres of the paper. The size, however, constitutes a very suitable fixing medium for coal-tar dyes, whether it be made from rosin or wax.

The process of using direct cotton dyes is to size first, then to neutralise any excess of acid with the smallest possible quantity of soda, and then to add the dye. If the waste water is not properly clear, a little Glauber's salt may be added.

Dyeing Straw. The value of straw depends upon its length and toughness, as regards the dyer's point of view, and in both these respects rye straw probably holds first place. Straw intended for hats is obtained from grasses (usually wheat, which is largely cultivated for this purpose in Tuscany), grown solely from the point of view of straw production, and the plants are cut down before they are thoroughly ripe. The straw is then bleached in the sun on grass, exactly as linen is, with occasional sprinkling with water.

If chemical bleaching is resorted to, chlorine is the most reliable agent, although peroxide of hydrogen or sodium answers nearly as well. Chlorine is apt to tender the straw, especially if its action is unduly prolonged, or if the straw is not well rinsed afterwards. Sulphur bleaching is usually only temporary; the straw gradually returns to its original colour on exposure to air and light.

Preparing Straw for Dyeing. The preliminary treatment before dyeing consists in softening the fibre as far as possible, in order that the dye may penetrate. At the same time, the process removes all grease and other foreign bodies which would cause unlevel dyeing, as well as any soap which may still remain in the straw. This softening is usually effected by soaking first in a weak lye of carbonate of soda, and then in water, which may be used cold, warm, or boiling, according to circumstances.

Dyes for Straw. Dyewoods were formerly largely used, and they are still in current use, especially Brazil wood and logwood, but nine-tenths of all the straw dyeing nowadays is done with coal-tar dyes, with a preliminary bleaching if a light colour is desired. Coal-tar dyes should be chosen which are soluble both in alcohol and in water, as strong tinctures can be kept in stock and diluted with water as required for use. Direct cotton dyes are chiefly used, and the only requirements which have to be fulfilled are good colour and fair fastness to light.

As a general rule, mordanting, when necessary, has to be done at the boil, and the dyeing also. Although substantive dyeing of straw can, as a rule, be done without boiling, it is advisable to boil even with substantive dyes if great fastness is desired. The time of boiling varies with the mordant and the dye, and the mordanting and the dyeing may each take from half an hour to two hours, according to circumstances.

Dyeing Grass. Most grasses, like plant fibre in general, can be easily dyed in fairly durable tints, and all dyes which can be employed for wood or straw are suitable for grasses. Practically, nowadays, coal-tar colours are almost exclusively used, and most of them require no mordant. The extracts of cutch, curcuma, the redwoods and logwoods are, however, sometimes employed. Aniline dyes are kept by the grass dyer in concentrated solutions in water or spirit, which are diluted for use as required.

Dyeing Wood. Woodworkers rarely call their tinting processes dyeing, but rather staining, yet this is really superficial dyeing. Wood is dyed by brushing over it a solution of the dyestuff or by immersion in the dye-bath. The method may be preceded or followed by the application of a mordant, also in solution, applied hot or cold.

Wood chip and plaited straw, largely used for hats, are dyed very simply after the fashion of wood and straw respectively.

Dyeing Feathers. Before feathers can be dyed or bleached they must be cleaned from dirt and grease. This is done with warm soap and water. Rinse afterwards, first in warm and then in cold water. If preferred, the feathers can be cleaned with petroleum ether. The best bleaching agent, and one which does not injure the feather, is peroxide of hydrogen.

Any method of dyeing wool may be practised with feathers, the most usual dyes employed being the acid wool dyes, used with either sulphuric or acetic acid.

Very beautiful effects can be got by spraying the feathers with very minute drops from a sprayer. In this way different parts of a feather can be dyed different colours, and the various hues may be made to pass gradually into one another.

Dyeing Marble or Stone. The only way to colour marble or stone is to form the pigment in the stone by soaking the mass first in one solution, and then in another, which, by reacting chemically with the first, will produce the pigment desired. For instance, the successive use of potassium ferrocyanide and ferric chloride produces a blue. The use of solution is, however, attended with considerable practical difficulties. In close-grained stones, such as marble or hard limestone, penetra-

tion is difficult; and when the second solution is employed the first portions of pigment produced are near the surface of the stone and hinder the penetration of the second liquid. The secret is to employ liquids which produce pigments of great body, so that even a thin deposit just below the surface will give a sufficient colour.

Dyeing Horn. Horn is of the same substance as hair and finger-nails and the feathers and beaks of birds. Horn often requires bleaching before dyeing, on account of its strong natural colour in many cases. Peroxide of hydrogen seems to be the safest agent, and gives good results in careful hands.

Horn is dyed principally with coal-tar dyes, but dyewoods are also used to some extent. Black, though it can be dyed with anilines, is commonly got by the use of a warm solution of lead-salt, which forms lead sulphide with the sulphur of the horn.

Dyeing Ivory. Ivory has no chemical affinity for colouring matters. The permanence of any artificially produced colour upon ivory depends, therefore, on the protection of the bony matter into which the colour has penetrated to some extent. The processes employed in dyeing ivory are very similar to those used for bone, but there are two points of difference between bone and ivory. In the first place, ivory has far less organic matter in its constitution than bone, and, in the second, it is much denser and closer in texture than bone.

The first of these differences is in favour of the ivory dyer. He has no fatty constituents to contend with, and these are perhaps the worst difficulties in the way of getting level shades, and are very troublesome to remove. The second, however, cuts the other way. Successful dyeing of ivory depends little on the colouring matter used. Once a dye or a lake has been formed in the superficial layers of the mass, the ivory is coloured, and the colour is protected by the hard tissue of the bone. Penetration is therefore the main thing to be considered, and it will be evident that prolonged heating is usually required in dyeing such a closely knit substance as ivory.

Dyes for Ivory. Black is dyed on ivory with logwood and bichromate in two baths, and also with Nigrosine. Red is dyed with cochineal or Brazil wood. Another method is to boil scarlet wool in water, adding carbonate of potash at intervals until the dye is extracted. A little alum is then added, the solution is filtered, and the ivory is soaked to shade in the filtrate. The dye liquor must on no account be hot, but it is advisable to have it warm to save time. Picric acid or other soluble dye gives an excellent yellow, as does fustic on a tin mordant. Blues are dyed almost exclusively with anilines, which have practically ousted indigo-carmine from the ivory painter's palette. Methyl violet of various shades is used for violet. Greens are dyed with anilines, or by combining a yellow with a blue. Browns are dyed with anilines—such as Bismarck brown—and with cutch, but most of the ivory in this country is dyed with permanganate of potash, like wood. Most of the aniline browns can be shaded with red or other colours. Greys are got with baths which are the same as for black, but weaker.

Dyeing Vegetable Ivory. Vegetable ivory is the kernel or albumen of the seeds of a South American plant known as *Phytelephas macrocarpa*. It is always dyed with coal-tar colours, but the dyeing requires special experience, as the texture of the substance varies greatly with the age of the plant, the time of harvesting, and with the variations in the climate which occurred during the ripening of the fruit.

With the softer kinds of vegetable ivory a boiling with soap, followed by a good rinse, helps the absorption of the dye. Among the coal-tar colours used, nigrosine, picric acid, malachite green, methyl violet, and fuchsine are the most generally employed. Dyewoods are still used, however, to some extent, especially cutch and logwood.

Dyeing Bone. The dyeing of bone is a comparatively easy matter, as the coal-tar dyes penetrate it very readily, especially in hot solutions. In the great majority of cases no mordant is required. In the case of basic dyes the best mordant is tin-salt.

Dyeing Mother-of-Pearl. Mother-of-pearl is difficult to dye, on account of its hardness and close texture. It is usual to dye the finished object, such as a button, as it is impossible to dye through thick material without injuring the lustre. Articles made out of mother-of-pearl dyed before fashioning remain colourless at the edge. The rough and damaged places of the button or other article are first dyed; the dye goes most strongly into defective places, such as edges and cracks, so they become coloured before the lustrous surface is dyed. Mother-of-pearl is sensitive to the action of chemicals, and hence it is necessary to use very weak acid solutions, only lukewarm, and to let them act for the shortest possible time only.

Preparing Mother-of-Pearl for Dyeing. The first thing to be done is to free the mother-of-pearl from grease, and, if light colours are to be dyed, it must then be bleached.

The dyeing is done cold if possible, and it is better to dye for a long time in a warm bath than to hasten the process by greater heat. The greater the lustre of the mother-of-pearl, the harder it is to dye it. As the dye ought not to injure the lustre, time should only be allowed for the dye to get into fine cracks and between the layers, watching the process with a good magnifying glass.

In dyeing with acid dyes, make the dye to a paste wth acetic acid, adding to the bath a little oxalic acid. In dyeing with adjective dyes the result is usually dull. Mother-of-pearl is most easily coloured in spirit dyes, but the colours obtained are looser than the above.

Dyeing Celluloid. Celluloid is invariably dyed with coal-tar colours. For single colours the coal-tar dye is added to the materials in the process of incorporation. For dyeing patterns on celluloid, the finished article is coated with a resist, usually paraffin or beeswax, and the parts to be dyed are then laid bare. The whole article is then immersed in a cold solution of the dye. In a few cases heat may be required to make the dye penetrate, in which case a comparatively infusible resist, such as asphalt, is used. In no case, however, may too much heat be used, or the celluloid itself will be softened and lose its shape.

APPLIED CHEMISTRY CONCLUDED—END OF GROUP 6

The Commercial Side of Shipping. The Shore Departments. Marine Officers and Seamen. Training, Promotion, and Salaries.

THE MANAGEMENT OF SHIPS

THE supremacy of British shipping is due principally to the efficient working of its commercial side. Nearly one out of every two merchant ships afloat is under the Red Ensign, and this because shipping in this country is a highly organised commercial business, free in its working from control of any Government department. Subjected as it is to free competition of home and foreign rivals, every improvement in steam navigation has been eagerly taken advantage of, and every economical device to save fuel or the expenses of working a ship is tried, and, if proved effective, adopted by the British shipowner.

Management. Each of the large shipping companies has its own method of management, which has been evolved by its directors and managers from their experience and knowledge of the particular requirements of the services their vessels perform.

In the case of a large limited liability company, such as the principal liners belong to, there are, of course, the directors elected by the shareholders, and a manager or secretary appointed by the directors. In the case of privately owned firms, there are one or more managing partners, who look after the business. The directors or partners decide the general policy and the particular trades on which their vessels run; they fix rates of freight and passage money, sometimes in conference with other shipowners, more frequently in rivalry with them, and in deciding these matters the directors have available their managers or other experts, who are in most cases the heads of departments.

As methods of management vary, so does organisation; but, generally speaking, in the larger companies, at any rate, it would be somewhat as follows. First would come the manager or secretary — in some cases there are both — who, subject to the directors, is in charge of the whole business, and under whom come the heads of the various departments, who report to the manager and take their orders from him. The various departments, generally speaking, would be as follow.

Accounts and Statistics Department. This department is usually under charge of an accountant well versed in shipping matters, and is one of the most important branches. All the bookkeeping is done here. Voyage accounts are compiled, profit and loss sheets made up, statistics of all sorts brought out, and generally everything pertaining to figures and working costs are furnished at call from this department.

The shipowner of to-day can quote an intending charterer with a rate for his steamer at once by referring to his accounts department, and if he proposes to send his steamer on a particular voyage outside the ordinary run, he calls for and is furnished with a pro forma voyage account, which puts before him the probable voyage expenses and earnings, and he quotes his rates accordingly. An account of this kind would be drawn out something as under.

PRO FORMA VOYAGE ACCOUNT

s.s. ——— ——— tons gross ——— nett

Voyage from —— to —— —— days speed — knots.

DISBURSEMENTS		EARNINGS	
Wages of crew — days @ £	= £	In this column would appear the estimated earnings worked out as so many tons at the rates to be quoted.	
Port and light dues ..	= £		
Victualling — days @	=		
Loading and discharging — tons @	=		
Coal — per day = total tons @ —	—		
Depreciation on £ @ per cent.	=		
Insurance on £ @ per cent.	=		
Deck stores	=		
Engine stores	=		
Repairs and sundries	=		
Commission account	=		
Total	£	Total	£

Estimated profit on the voyage = £

Rate per ton per month = £

For steamers going through the Suez or Panama Canals, the canal dues would appear a big item on the disbursement side. The department has records showing the port dues, loading and discharging rates, and cost of coal at practically every commercial port. The depreciation and insurance are calculated on the book value of the steamer, and the average cost of many voyages gives the figures for deck and engine stores and repairs. In this department a practical knowledge of bookkeeping, of exchanges and figures generally, is necessary.

Marine and Engineering Department In small companies owning up to, say, half a dozen small steamers, or of one or two steamer companies, the masters and chief engineers of the vessels discuss with the owner the repairs, etc., required, and tenders for these are called for, and, as a rule, go to the cheapest offerer. Every big line, however, has a marine superintendent and a superintendent engineer (usually one of the most efficient and trusted commanders and chief engineers selected and taken ashore on the staff for the purpose), and they are responsible for all technical details connected with the deck and engine-room departments. In their hands, too, are left the selection and appointment of officers and engineers, as well as the promotion and transfer of the marine and engineering staffs. All questions of repairs, alterations, and so forth are dealt with in this department, and in the case of new vessels these officials give to the directors and managers the benefit of their technical advice.

These experts report on new inventions, and recommend their adoption or otherwise. When a new patent is adopted, close observation and record is made of its efficiency, and this department looks after all such records. The logs of the various steamers are entered up, their mileage and speed tabulated, their coal and oil consumption noted,

and in the case of excess over the usual average the captain and chief engineer are called on to explain the reason. In this way a check is kept on coal and oil expenditure, and careful and efficient marine and engineering superintendents mean much in the economical working of a big line. Besides the superintendents, the staff in this department is usually made up of one or more draughtsmen, an electrician, two or three junior clerks, and a few typists.

The young man entered in this department should apply himself to obtaining an accurate knowledge of the technical names of the different parts of a ship and her machinery.

Coal and Stores Department. On an estimate prepared for the year, this department will call for prices from contractors on their "suppliers list," and make contracts for the stores and coal required for the period fixed, usually six months to a year. In the stores department will be found samples of all the innumerable articles required by a modern ship, such as cordage, manilla and wire ropes, oils and paints, canvas, ironmongery, lamps, electroplate, cutlery, earthenware and glass, napery and linen, etc. These samples are carefully compared with the goods delivered by the various contractors, and any departure from sample is brought at once to the notice of the offending party.

When an "indent," as it is usually termed, meaning a requisition for stores sent in by the deck and engine departments, has been passed by the superintendent concerned, it is sent to the stores department. Here it is dissected, and orders sent for the stores indented to the various contractors.

A few junior clerks suffice for the work here, which is mostly routine, sending out orders and carefully checking suppliers' invoices with the ships' receipts and contracts. The responsible official in charge of this department is known generally as "the ship's husband," a happy description indeed.

Victualling Department. In close connection with the stores department is the victualling department. In some companies, in fact, they are one, and the stores do the victualling work as well. The shore purser or superintending steward is in charge here.

Into this department come the indents from the chief stewards of the various steamers, giving their requirements for provisions, meat, wines, etc., for the next voyage. These requirements are based, of course, on the number of passengers to be carried and on the length of the voyage. Striking figures have been published of the huge piles of perishable stores, of the mountains of bread, fish, fowls, meat, hams, eggs, and so forth, consumed on a voyage of one of the Atlantic greyhounds, but such statistics scarcely come within the scope of this article.

Regular and careful accounts are kept, and on the averages a daily victualling scale is fixed to which chief stewards have to conform. The picking and selection of the chief stewards is in the hands of the shore chief, and a good and careful chief ashore is usually reflected in the work of the men afloat.

General and Correspondence Department. This department has usually at its head the general manager or secretary. In the case of firms owning a few steamers it is run directly, very often, by the partners themselves. The staff is usually the largest in a shipping office, as all the general routine work of an ordinary business office is dealt with here. Here, also, is the cash department presided over by the cashier.

Passengers are booked, passage tickets issued, and inquiries answered. Sailing and advertisement cards usually adorn the walls, and cabin plans of the company's steamers lie on the counters.

The young man entering a shipping office usually begins here, being drafted to other departments later for experience, or according to his aptitude. He starts, as a rule, by copying letters and documents and fetching and carrying for his seniors. A knowledge of shorthand should be possessed by every youth, and if he is able to use a typewriter so much the better. Typists, however, are usually engaged as such and kept to that work. There is a call also for a knowledge of languages, particularly French and German. The development of intercourse with South America makes Spanish a useful acquisition, and Russian will be of immense service in the business of shipping in the coming generation.

Freight and Bills of Lading. This department looks after the engagement of freight, etc., and is usually divided into export and import sides. The export issues bills of lading for goods shipped from the home ports abroad, while the import department deals with the manifests and bills of lading for cargoes coming into the home ports.

In these days of keen competition the shipowner has to hustle to secure his freights. He does not wait for the shipper to come to him, but looks after the shipper. In London a representative of this department will be a member of the "Baltic." In Liverpool and Glasgow business is done on the "Exchange," and in Newcastle on the "Quayside," as the shipping exchange there is called locally. The "Baltic" in London is a palatial edifice in St. Mary Axe, replete with all comforts for its clients, and this may be termed the hub of the freight market in London. Here shippers and shipowners have full information as to freights and rates, and here they do their deals.

The freight department watches the trade journals, notes all big orders placed for railway materials for abroad, and then puts freights forward to the firms concerned. Here the early bird often catches the freight worm, and canvassers with a keen eye for business and an attractive manner are invaluable.

The freight being engaged, arrangements are made for shipment by a particular steamer. It is sent alongside by rail or barge, as is cheapest or most convenient, and is at the ship's risk from the time it leaves the quay wall or barge till clear of the ship's tackle when landed at the port of destination. As cargo comes on board, it is "tallied"—that is, a note is taken of the cargo, whether it is case, package, etc., and the "mark." A receipt is given, and this receipt, being presented to the freight department along with a bill of lading (which is usually in triplicate), is signed by the department "for the master," and it is then the merchant's title to the goods described. Only on production of this bill of lading, or an indemnity freeing the shipowner of all liability, will the goods be delivered to the consignee.

Particular trades, such as the Black Sea, Mediterranean, etc., have their own particular form of bill of lading, and most of the large companies have also a special form bearing their house flag or distinguishing emblem.

The Bill of Lading. The bill of lading gives the names of the shipper and the consignee, the name of the steamer and master, the port of shipment and the destination, the number of packages, and the date. On the margin is detailed the number of packages, their contents, and marks. Freight is payable on delivery of the

bill of lading "ship lost or not lost," and a recital is given of all the liabilities from which the shipowner frees himself, including "the act of God, the King's enemies, robbers by land and sea, restraint of princes, rulers, or people"; and such commonplace things as "strikes or stoppages of labour."

The shipowner has a lien on goods shipped for his freight. He is held responsible for loss or damage or short delivery, provided he has granted a "clean" bill of lading—this is a B/L without any remark as to the cargo being damaged or in bad condition.

All packages, as a rule, bear a mark, not an address, and all large shippers have their own particular mark, many of them well known in trade to the general public. Underneath the mark is the port of destination, and the package is usually numbered as well.

Sample marks are given below.

A mate's receipt granted on delivery to the ship and on which the bill of lading is made out would read something like this:

s.s.———

Date

Received in good order and condition on board the s.s.———, ——— Master, the undernoted goods.

New York. ABC $ 1/3 3 *cases hardware.*

(sgd.) J. SMITH,
2/ mate.

A considerable number of clerks are employed in the freight department. Bills of lading for large ports have each, as a rule, a separate desk assigned to them, and the clerks employed check the bills of lading produced by the shipper with the mate's receipts, and make out the freight notes. This requires careful calculations. Goods are shipped on weight or measurement at the option of the steamer, and one freight note will involve many calculations of weight and measurement rates of freight.

The young man coming to this department needs all his wits about him. He must be careful and methodical, with a quick and accurate knowledge of figures. Here outside work is regarded as the "plum," and the ambition of the smart man is to get on the "Baltic," or shipping exchange, and do the outside freight work.

There is also usually an expert attached to this department skilled in estimating damage and settling losses. The outside public have little knowledge how many and various are the claims made by shippers for damaged or missing cargo. A smart, tactful man can save his employers thousands of pounds a year in the working of the "claims" department.

Insurance Department. In all large shipping companies there is an insurance department. It is usually in charge of an experienced man well versed in marine insurance law and customs. Many of the large shipping companies insure their steamers in a special fund of their own, and find it pays them to do so. The premiums, ranging as a rule from 4 per cent. to 6 per cent., are charged against each steamer's earnings, and credited to the "insurance fund." Against the insurance fund all claims for damage and losses are debited. The larger companies insure the cargo carried by their own steamers, and the baggage of passengers. In the case of companies where the insurance is done "outside," the risks are taken by Lloyd's and the other great maritime insurance companies.

On the outbreak of the European War (1914), the Government made arrangements with Lloyd's and other insurance companies to reinsure 80 per cent. of all risks to shipping insured by them.

Lloyd's. In marine insurance matters Lloyd's overshadows every other concern. It is also the great organisation for the collection and distribution of marine intelligence. All round our coasts and in every part of the world Lloyd's agents advise the movements of the ships of all nations, and not one vessel in ten bound to ports in the United Kingdom arrives as her terminal port without being "reported at Lloyd's."

Lloyd's, too, has a "Captains' Register," showing the service of every master in the mercantile marine, and in this connection much valuable and confidential information of great value to underwriters is available for the benefit and guidance of members and subscribers.

An inquiry office is also maintained by Lloyd's where relatives of the crew or passengers may obtain without cost information regarding the movements of the vessel in which they are interested.

It is scarcely within the province of this article, and space forbids any particular description of the business of Lloyd's, or the clauses which make up its marine policies, but to anyone engaged in shipping a knowledge of the abbreviations used is not only useful but necessary. Hereunder is a table of common abbreviations.

H.C.	Held covered.
S.A.	Subject to approval.
N.R.	No risk.
U.K. or C. ..	United Kingdom or Continent.
Cont. H. and H.	Continent between Havre and Hamburg.
Cont. B. and H.	Continent between Brest and Hamburg.
F.O.	For orders.
O.P.	Open policy.
F.C. and S. ..	Free of capture and seizure.
D.C.	Deviation Clause.
T.L.O.	Total loss only.
F.A.A. ..	Free of all average.
F.G.A. ..	Foreign general average.
Y.A.R.	York Antwerp rules.
R.I.	Reinsurance.
R.D.C.	Running down Clause.
C.C.	Continuation Clause.
D.C.	Detention Clause.
L.C.	Label Clause (Bottled goods).
F.P.A.	Free of particular average.
P.A.	Particular average.
G.A.	General average.
P.L.	Partial loss.
S.L.	Salvage loss.
C.T.L.	Constructive total loss.
T.L.	Total loss.
W.P.	Without prejudice.
Wd.	Warranted.
W.A.	With average.
P.P.I.	Policy proof of interest.
A.R.	Against all risks.
W.O.B. ..	Washing overboard.

Lloyd's has a close connection indeed with the commercial side of shipping, and from the "A1 at Lloyd's," which describes the highest class granted to a merchant ship when she starts her first voyage, till her disappearance through loss or breaking up Lloyd's never loses sight of her.

In Lloyd's Register appears the name of every steamer and sailing ship afloat, showing the owner's name, the name of the builder, the classification, tonnage, and her general measurements, as well as her official number and port of registry.

The Merchant Shipping Act. This Act defines the duties and responsibilities of owners, masters, and crews, as well as the machinery of the

Board of Trade Mercantile Marine Offices (known to Merchant Jack as "the Shipping Office") and others authorised to deal with ships and seamen. The Act of 1894, in its 744 sections, amended and modified by the Merchant Shipping Acts Amendment Act, 1906, and other Acts, provides for practically every point likely to arise in connection with the owning or management of British vessels.

The first section of the Act gives the qualifications necessary for owning British ships, wherein it is laid down that a ship shall not be deemed to be a British ship unless owned wholly by persons of the following description, namely: (*a*) Natural-born British subjects; (*b*) persons naturalised by or in pursuance of an Act of Parliament or ordinance in a British possession; (*c*) Persons made denizens by letter of denisation, and (*d*) Bodies corporate established under and subject to the laws of some part of the King's dominions, and having their principal place of business in those dominions. It is under the last qualification, of course, that the great majority of British shipping is registered.

The second section of the Act provides for the registry of every British ship, and accordingly the first proceeding of an owner of a British vessel is to register her, and the procedure as to this is laid down in Sections 4 to 20 of the Act.

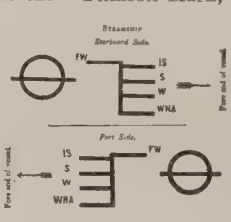
Registering a Ship. When a new steamer is built she is measured for tonnage by a Board of Trade surveyor, and the measurements so ascertained are embodied by the shipbuilder in a document known as "The Builder's Certificate," which is handed to the owner, who, on the figures given therein, makes out his "declaration of ownership." This document gives the name of the owners, their principal place of business, and the number of shares in the vessel. A vessel is divided into 64 shares, so that a sole owner would be described as owning 64/64th shares. This document, then duly signed before a shipping master or a commissioner of oaths, is handed in along with the builder's certificate and the certificate of the master, to the registrar of shipping at the port where the vessel is to be registered. The registrar then allots the vessel her "official number." This number having been carved on the main beam of the vessel, and her port of registry painted on the stern, and a carving note signed by a surveyor to that effect being furnished, the registrar grants the "certificate of registry." This is the vessel's most important document. It is at once her birth certificate and passport; without it she cannot obtain clearance from any port, and failure to produce it would render a vessel liable to seizure as an ownerless and suspicious craft. The certificate of registry shows the vessel's name, official number, and port of registry, gives full details of her measurement and tonnage, and the name of her owners and her master.

Selling a Ship. In the purchase or sale of a British ship there is little formality, no need for a lawyer, and the process is simplicity itself, a steamer valued at a million pounds being more easily disposed of than land or a house worth a hundred. The seller signs and seals a document known as a *bill of sale*, which gives the name of the steamer sold, and other particulars from her certificate of registry, the names of the sellers and buyers, and this document being handed over to the registrar of shipping at the steamer's port of registry, the old register is closed, and a certificate granted to the new purchaser, and the business is done. The bill of sale in its wording is a quaint survival of the days when the merchant ship was armed, as in its wording it transfers the shares "in the ship above particularly described, and in her boats, guns, ammunition, small arms, and appurtenances." The modern vessel, however, as a rule, has neither guns, ammunition, nor small arms, but the form survives. If a British vessel is lost, taken by the enemy, or sold to foreigners, notice of the fact must be given, under penalty, to the registrar, who thereupon closes the vessel's register, except in so far as any unsatisfied mortgages are concerned. The owner is bound to give up the ship's certificate of registry if the steamer is sold to foreigners, or if it is saved in the event of wreck.

Legal Rights of the Crew. The Acts provide and lay down conditions for the engagement of a crew, and every member of the crew must have the agreement read and explained to him by the shipping master or his deputy. Facilities are granted to seamen to complain of any grievance, and pains and penalties are enacted to protect the seamen from imposition of any kind. Even his food is provided to scale laid down in his agreement, and his quarters are certified to accommodate the number of crew.

"Jack" nowadays is quite competent to look after himself, and demand what he terms his "rights," and his trade union—the Seamen's and Firemen's Union—is vigilant in this matter.

In the agreement with the crew the freeboard of the steamer is given. This is a change from the bad old days of the "coffin ships," and the fixing of a safe freeboard was one of the points so strenuously fought for by the "seaman's friend," the late Samuel Plimsoll, M.P. The load-line cut and painted on the side of every British ship is known universally as the "Plimsoll Mark," and is shown below.



The letters shown on the load-line mark are FW, fresh water; the load draft of the vessel in fresh water, IS, Indian summer; S, summer; W, winter; and WNA, winter North Atlantic. The British load-line regulations are accepted by nearly all foreign Governments.

Part II. of the Act deals with masters and seamen, and makes provision for apprentices being carried. It also provides for the examination and grant of certificates to competent men, and states the conditions for the issue of licences to supply seamen, and for their engagement. The rating of A.B.—that is to say, able-bodied seaman—is granted only when the seaman has served at sea for three years.

Elaborate instructions are laid down regarding the discharge of seamen, payment of wages, seamen's money order and savings banks, and the property of deceased seamen. By law, everyone on a ship's articles is a "seaman," and when a seaman dies on board a British ship his wages and effects must be handed over by the master of the ship to the Board of Trade, who transmit these through a shipping office to the relatives of the deceased. Provision is made as to discipline, and for an official log, wherein is entered the record of any offences, births, deaths, etc. To be logged, to a seaman means much the same as a police conviction to a landsman.

The records of the service of all persons who serve in ships is kept at the office of the Registrar-General of Shipping and Seamen. The appointments of the Registrar-General and his staff are made by the Board of Trade, which, with the consent of the Treasury, regulates their salary and allowances. In this office are collected all the statistics as to

seamen, etc., also records of deaths, births, and marriages on board any British ship.

Provisions for Passengers. Part III. of the Act deals with passenger and emigrant ships, regulates their equipment and fixes the number of passengers or emigrants they may carry. As to emigrants, the Act fixes that as regards steerage passengers no ship may carry more than :

(*a*) If the ship is a sailing ship, one adult to 33 tons of the ship's registered tonnage ; and

(*b*) If the ship is a steamship, one adult to every 20 tons of the ship's registered tonnage.

A ship must not carry passengers, cabin or steerage, on more than one deck below the waterline. Provision is made for the survey of passenger steamers, for the general equipment, for the maintenance of order, for the supply and inspection of provisions, water, and medical stores, and so forth.

Sundry Regulations. Part IV. of the Act deals with fishing-boats, and relates to " all fishing-boats and to the whole fishing service."

Part V. is headed " Safety," and deals with regulations for the prevention of collisions at sea, regulates the lights to be carried and exhibited, the fog-signals to be used, and the steering and sailing rules to be observed. It also deals with the load-line, the loading of timber, and carriage of grain, and unseaworthy ships.

This part of the Act is now greatly modified by the Merchant Shipping (Convention) Act, 1914. All vessels carrying 50 persons or more are required to be fitted with radiotelegraphic apparatus capable of transmitting signals at least 100 sea-miles.

Part VI. sets up the machinery for special shipping inquiries and courts ; and Part VII. deals with delivery of goods and lien for freight.

Part VIII. defines the liabilities of shipowners, which the Act declares to be—

(1) In respect of loss of life or personal injury, either alone or together, with loss of, or damage to, vessels, goods, merchandise, or other things, an aggregate amount not exceeding £15 for each ton of the ship's register ; and

(2) In respect of loss of, or damage to, vessels, goods, merchandise, or other things, whether there be in addition loss of life or personal injury or not, an aggregate amount not exceeding £8 for each ton of the ship's tonnage.

Part IX. deals with wreck and salvage, the registration of marine-store dealers, the appointments of Receivers of Wrecks, etc. ; Part X. fixes pilotage, and applied to all ships, British and foreign, but this has been repealed by Pilotage Act, 1913, under which pilotage of vessels is now regulated. Part XI. deals with lighthouses and the levying of light dues, which under present arrangements are all borne by the shipowner, and which he justly claims should, in the United Kingdom, as elsewhere, be borne by the State.

Part XII. refers to the Mercantile Marine Fund, which deals with all charges in respect to fees for survey of ships, fees paid at the various shipping offices, etc. It is modified by Mercantile Marine Fund Act, 1898.

Part XIII. deals with the methods of legal procedure ; and Part XIV. is supplemental, and defines the general control of the Board of Trade, the appointment of surveyors and inspectors, and the power of Colonial legislatures in regard to shipping.

The Mercantile Marine as a Profession. The mercantile marine offers an excellent career to the man of steadiness and intelligence. There are three departments open to the youth who decides to follow the sea : (*a*) as a deck officer ; (*b*) as an engineer ; and (*c*) the saloon department, as purser or steward.

To qualify as a *deck officer*, the youth must serve an apprenticeship, and he may do this in several ways. He may be sent by his parents to the training ships Worcester or Conway, for the two years' school course there. This will cost parents about £60 a year, but the boy gets a splendid training in seamanship and navigation, as well as an excellent general education. These two years in the Worcester or Conway are allowed to count as one year's sea service, but to be qualified to sit for examination for a second mate's certificate the youth must now serve three years at sea ; this he can put in as an apprentice in a sailing ship or as cadet or midshipman in a steamer. There is no difficulty in getting a youth apprenticed or appointed as a cadet. The large steamship companies, such as the British India Line, the New Zealand Shipping Company, Shaw Savill & Albion Co., Bucknall Bros., the Gulf Line, now carry cadets or apprentices, the premium ranging from 30 to 100 guineas, which is returned to the boys as wages. These companies endeavour to give the cadets a knowledge of seamanship, navigation, and the general duties of a navigating officer, but the steamer-trained officer is seldom up to the standard of the youth trained in a sailing ship.

A young man may also qualify by serving before the mast, as boy and O.S. (ordinary seaman), and many excellent captains and officers have begun their sea profession in the forecastle.

Nautical Examinations. After completion of the four years sea time the youth goes up for the Board of Trade examination for a second mate's certificate, and this obtained, he is fully qualified as a junior officer in the mercantile marine. The supply of officers is less than the demand, and the young man should experience no difficulty in obtaining a berth as fourth officer in one of the " liner " companies. His pay will run from £5 to £6 a month, with " all found "—that is to say, assuming a youth goes to sea between 15 and 16 years of age, by the time he is 20 he is in a position to keep himself. His first step is to third officer, when he is in charge of a watch ; this step he should get in from a year to eighteen months in most large companies, and he now puts in his time for chief mate's certificate. This obtained, he is eligible for promotion to second officer, which rank he should reach after three to five years' service. Then he passes for master, and obtains afterwards, if he can, an extra master's certificate as the result of a further and special examination. Promotion to chief officer reaches him after seven to ten years, depending on the company he serves, and he reaches command after fifteen to twenty years' service. His pay as chief officer will run from £12 to £18 a month, and as commander from £20 to £60 a month, and in some exceptional lines and services he may get £800 to £1,000 a year.

Promotion. Promotion to command goes by seniority, tempered by selection, and the smart and efficient chief officer, as a rule, gets his command before men senior to him, who have not shown themselves so zealous for their employers' interests.

The large shipping companies, as a rule, engage only young officers, and train them themselves. These juniors receive promotion to the higher grades as vacancies occur, and only in exceptional cases is an officer or commander brought in over the heads of men in the service.

Application should be made in writing to the manager or marine superintendent of the line

selected, and the letter should be accompanied by copies of testimonials. This, as a rule, brings a reply, asking the applicant to call for a personal interview, and the interview being satisfactory, and his papers in order, an appointment follows.

Marine Engineers. To qualify for a marine engineer, an apprenticeship of at least five years must be served in an engineer's establishment—a marine engineer's shop for preference. Here the youth should begin at the age of 15 or 16, so that he will finish his time when he is between 20 and 21 years of age. During his apprenticeship the youth who desires to get on will attend evening technical classes in drawing, machine construction, and kindred subjects, all of which he will find most helpful when he goes up for his Board of Trade examinations, and throughout his career. The great marine shops are on the Clyde, in Scotland, and on the Tyne and the East Coast of England, and Belfast in Ireland. As a rule, no premium is charged, and in fact the majority of engineers regard the premium apprentice with suspicion, considering he is likely to have too much false dignity to learn his business properly. Wages are generally paid the apprentice, say 4s. a week the first year, rising by 1s. or 2s. a week each year of the five he serves. His apprenticeship completed, the young man should send in his application to the superintending engineer of three or four of the big companies. He should state clearly where he served his time, what special certificate he holds, his age, and send a copy of his apprenticeship certificate. When appointed, it may be as tenth engineer, or even as fifth or fourth, depending on the size and power of the steamer to which he is posted.

His ambition is now to get his time in as a watch-keeping engineer, to enable him to obtain his second and chief engineer's certificate. Usually the second's examination is passed after about eighteen months to two years' sea service, and a chief's certificate is obtained after four to five years' sea service. A longer period of service is required where the steamer is a home-trade vessel than where it is a foreign-going steamer. Promotion depends on the line in which the engineer serves. He should be third after three to four years, second after seven to eight years, and chief engineer after 15 years' service. The pay of a junior engineer begins at £7 to £8 a month, with "all found"; as third he will receive £10 to £12, as second £14 to £18, and as chief £20 to £40, depending on the number of years' service. The chief engineer earns a bonus on savings in coal and oil consumption.

Pursers and Stewards. Only the large passenger boats carry pursers, and their duties vary according to the line on which employed. In some of the companies he is a clerk pure and simple, doing the captain's correspondence, writing out manifests, passenger lists, etc.; while in other lines he combines these duties with the general oversight of the saloon department. Generally speaking, however, the duties of purser and steward are separate. The purser usually secures his appointment through the nomination of a director, and puts in a few months or a year or so in the office of the company before he is sent afloat. There is nothing particularly exacting in the duties of this office, and a young man of average intelligence can easily acquire a knowledge of them. Vacancies, as a rule, seldom occur in the big lines. Pay will run from £6 to £12 a month,

Pursers are carried by river and pleasure steamers during the summer months, and here the duties are more concerned with the collection and issue of passengers' tickets. There are many applicants, and the pay is small—from 10s. to 30s. a week, The young man who desires to go to sea as a steward must begin at the very bottom of the ladder, and, as a rule, he learns his experience in a hard school. The river and pleasure steamers, or in the steerage department of an Atlantic liner, would give an opening, and experience gained, the efficient steward works his way upward to chief by his own efforts. The pay of assistant stewards is nominal, and they depend on tips from passengers to a great extent. A chief steward will be paid from £8 to £12 a month. A knowledge of catering for passengers is essential to the efficient steward, and second only to this is tact.

Royal Naval Reserve. The officer or engineer desirous of serving his country or ambitious of social advantages, joins the Royal Naval Reserve. The qualifications necessary, aside from the fact that the applicant for a commission must be a British subject, are as under :

For midshipmen: a two years' course in one of the mercantile marine training ships, or a year at sea on board a first-class British ship. For sub-lieutenant : service as first mate of a first-class British steamship of at least 1,500 tons, or a sailing ship of 1,000 tons, and the possession of a master's certificate. Second and third mates are eligible provided that they have served for not less than six years at sea, excluding their time as apprentice, and for lieutenant, service in command of a steamer of 1,500 tons or a sailing ship of 1,000 tons is necessary for not less than one year.

A senior engineer must hold a first-class engineer's certificate, and have not less than 10 years' sea service, including three years as chief of a steamer of not less than 500 nominal horse-power.

An engineer must hold a first-class certificate and have seven years' sea service, including one year's service as chief engineer of a steamer of 200 nominal horse-power, or as second of a steamer of 500 horse-power, and an assistant-engineer must hold a first or second-class certificate and have served at least one year in a steamer as a certificated engineer.

Qualifying Drills. It is necessary for the lieutenant, sub-lieutenant and midshipman, to put in qualifying drills at stated periods, and such officers may volunteer to go through a twelvemonths' course of training in H.M. fleet. This course completed satisfactorily, officers are granted certificates, and become entitled to the following annual allowances: Lieutenants, £25 a year; sub-lieutenants, £20 a year; midshipmen, £10 a year.

Officers of the reserve when called out for training receive the same pay and allowances as officers of the corresponding rank in the Royal Navy, and while on service they are treated in the same manner in every respect.

Besides the experience, and the social polish which a training in the Navy undoubtedly gives, and considering that an officer can live on his pay while serving, the annual allowance granted certainly makes it worth while for a merchant service officer to serve in the Reserve.

The tonnage of the mercantile marine under the Red Ensign grows and increases with the years, and the shrewd brains which control it are as capable now as ever, and if only the youth of the country, gentle and simple, would do their share, and come forward as they did in the years gone by, as officers and seamen, there seems no reason why the preponderance of our lead in shipping matters should not be maintained.

The Characteristics of Good and Cheap Bindings. Sewing with Cords and Tapes. Covering and Tooling. The Attractive Trade of Book-publishing.

BOOKBINDING & PUBLISHING

BOOKBINDING

By F. Sangorski and G. Sutcliffe

Before entering upon the technical details of bookbinding, it will be advisible to give an explanation of the composition of a book, and of the sizes in which books are made. A book is printed on sheets, and the size of these sheets and the number of times which they are folded decide the size of the volume. The sheets are generally used in the following sizes: Foolscap, 17 in. by 13½ in.; medium, 24 in. by 19 in.; crown, 20 in. by 15 in.; royal, 25 in. by 20 in.; post, 19¼ in. by 15½ in.; super-royal, 27 in. by 21 in.; demy, 22½ in. by 17½ in.; imperial, 30 in. by 22 in.

When the sheets are folded once they make a folio-sized volume; twice, quarto (4to); three times, octavo (8vo); four times, 16mo; and five times, 32mo.

A book is said to be a "crown 8vo," or a "demy 8vo," when sheets of "crown" or "demy" size are folded three times. When folded, each sheet is called a *section*, and consists of the number of "leaves" into which the sheet has been folded—an 8vo volume having, for instance, eight leaves in each section—each leaf consisting of two pages. The top edge of a book is termed the *head*, the bottom edge the *tail*, and the front edge the *fore-edge*.

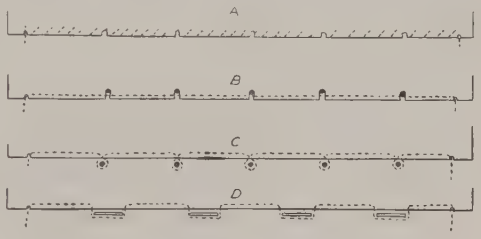
Bookbinding is divided into three branches—sewing, forwarding, and finishing. With sewing are included all the processes which ultimately end in the sewing of the sections together. Forwarding comprises the processes which complete the binding of the book; and finishing, the processes which result in the decoration of the binding.

Machine Binding. The demand for inexpensive binding, brought about by the increase in cheap literature, has led to the introduction of machinery into the craft. With publishers' cloth bindings, the processes from beginning to end are carried out by machinery. But though by this means cheap work is produced, it is usually at the expense of the quality of the binding. If the best work be required, it must be done entirely by hand, with just the aid of such appliances as have been in use almost since the invention of bookbinding. As, however, there are now so many books that are not worth the expenditure necessary for the best binding, the use of machinery is compulsory; but a method should be adopted that will allow the use of machinery without seriously damaging the binding. The essential requirements of a soundly constructed binding are: (1) All sections broken at the back should be mended, and all loose leaves and plates secured to the sections with a guard; (2) the book should be sewn on at least five cords or four tapes, which should project from the backs of the sections; (3) the boards should be firmly attached to the book, all the cords and tapes being interlaced into the board; (4) the leather should be directly attached to the back; and (5) all materials used should be of sound quality, uninjured during manufacture.

With the exception of the cheapest work—cloth binding—there is no reason why all these requirements should not be met; but owing to the demand for a showy exterior at a low price they are not usually considered by the modern binder.

Modern Cheap Binding. Usually, if the sections are broken at the back, the practice is to cut off a piece of the back, thus making the section into single leaves, and to sew these leaves together in the manner shown in **1** A. This is called overcasting, but a section so sewn together will always be liable to break away from the rest of the book and will never open freely.

With sewing, the cords, instead of projecting from the back of the book, are sunk into the sections, saw cuts being made in the back, the level back thus obtained enabling the book to be backed by machinery. But the sewing is not nearly



1. SEWING BOOK SECTIONS

as secure, for instead of the thread passing round the cords as seen in **1** C, it merely passes across them as in **1** B; and if broken, the probability is that the section will come out.

All books that are to be backed by machine should be sewn on tapes. The sewing is secure [**1** D], and the tape does not make sufficient projection to prevent the machine being used.

Too thin a cord is generally used, and often two are cut off, and only the remainder interlaced into the board.

The sinking of the cords prevents the book opening well, and to get over this to some extent, the leather is not attached to the back. A hollow casing made of brown paper is glued on, and the leather attached to this. The leather is attached to the boards, and the boards to the book merely by the cords laced into them; consequently, all the strain of opening and shutting the book is placed on these cords, and they often break away, the book then coming away from its cover. If the leather is stuck directly on the back, it assists the cords in attaching the cover to the book [**16**]. The cords have been sunk into the book, but as the public have been accustomed to see the projections on the back made by the cords, false ones are stuck on.

Good Inexpensive Binding. For the best binding the book should be sewn on cords, and meet all the requirements we have mentioned. If the question of expense has to be considered, the decoration should first be discarded. After that, leather being needed principally on the back and corners, only these portions need be covered with leather, and the remainder with a

Standing press *A*. Sewing-key 15. Press, with plough and pin 16. Correct and ordinary binding 17. Finishing press

less expensive material. This is what is called "half binding." For a further reduction the book should be sewn on tapes, and by this means an inexpensive and durable binding can be obtained.

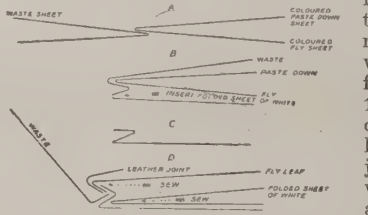
Following is a list of tools and appliances necessary: Standing press; sewing press [**14**]; sewing keys [**14** A]; bloodstone burnisher [**11**]; agate burnisher [**10**]; square; band stick; tenon saw; trindles [**5**]; bodkin [**9**]; pressing boards; cutting boards; backing boards; nickel pressing plates; set of letters, dots, rings, punches, leaves, flowers, gouges, straight lines, and other ornaments [**12**]; press with plough and pin [**15**]; paring stone; paring knife [**2**]; hammer; folders [**3**]; glue pot; compasses; band nippers [**6**]; knocking-down iron [**4**]; gold cushion and knife; pressing tins; millboard shears; finishing press [**17**]; finishing stove; fillet [**7**]; polishing iron [**8**].

If the book is received in sheets, these sheets have to be folded. We will suppose they are to be folded three times, making an 8vo volume. The sheets are lettered alphabetically in one of the corners [**13**]; these are called *signatures*. Usually, J, V, and W are omitted. The sheets are placed in alphabetical order with the signatures in the right-hand bottom corner. The first sheet is turned over, so that the signature comes face downwards on the left-hand bottom corner, and is folded in half from right to left, care being taken that the printing corresponds. A folder [**3**] is used to crease the fold. Pages 2 and 3 will now face. The top right-hand corner is then folded, and pages 12 and 13 will face. Folding in half, so that 8 and 9 face, completes the folding of the first section. The remainder are folded in a similar manner.

Washing Stained Sheets. Any stained sheets are washed in the following manner: An ounce of permanganate of potash is dissolved in a quart of slightly warmed water. The stained sheets are put into this solution for about an hour, causing them to turn a dark brown colour; they are then taken out and washed in clean water. One ounce of sulphurous acid is put into a pint of water, and the sheets washed in this until all the stains have disappeared. They are again washed in clean water, and hung up on lines to dry. When dry, they are sized by dipping them into a solution of one ounce of isinglass dissolved in a quart of water, applying heat and again hanging up to dry. If the sheets are too white when taken out of the acid, the size is slightly tinted with tea, coffee, or any other staining fluid.

Making Endpapers. When all the sections have been made sound and the plates guarded on, endpapers are made. They are attached in the following way. Two folded sheets of white paper, similar in tone to that on which the book is printed, and a folded sheet of coloured paper, are required. The coloured sheet is pasted on to one of the white sheets as shown in **18** A. When dry, the white leaf marked "waste sheet" is folded over one coloured leaf, and the other white leaf folded back over the remaining coloured one, as in **18** B. The other folded sheet of white is then inserted where marked, and the end paper is sewn on to the book through this. The waste sheet is for the purpose of protecting the end papers during the binding, and is torn out when the endpapers are finally pasted down.

If a leather joint is used, the endpapers would be made up in the following manner. A white sheet is folded as in **18** C, and the coloured fly-leaf, leather joint, and waste sheet, are pasted on to this as in **18** D. A folded sheet of white is inserted, thus completing the endpaper, which is sewn on in the two places marked in **18** D. The endpapers are placed in their positions



18. ENDPAPERS

at either end of the book and then tins covered with paper are placed between every three or four sections and the book placed in the standing press for about twelve hours.

The positions of the cords or tapes on which the book is to be sewn are then *marked up* on the back. The book is knocked up square at the head and held in the lying press between a pair of pressing boards and the back is divided into six divisions. Five of these are made equal and the tail one slightly longer. On the five points thick pencil lines are drawn across the back. If tapes are used for sewing four are usually sufficient and two lines are marked for each tape. A slight saw cut is then made at the head and tail about half an inch away from the edge, and the book is ready for sewing.

Sewing the Sections Together. The book is sewn on five cords; the number sometimes varies with the size of the book, but five is the most usual; the thickness of the cords also varies according to the size of the volume. Five loops are made of ordinary string over the crossbar of the press; these are called *lay cords*, and are used repeatedly. To these loops are attached the cords on which the book is to be sewn, which are then passed down through the slit in the bed of the frame and fastened by means of keys [**14**].

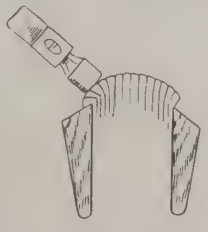
The book is laid down on the bed of the press with the back against the cords, which are moved into position so that they correspond with the lines marked on the back of the book. The cords are then tightened by screwing up the crossbar.

The endpaper is first sewn, the needle with thread or silk being passed into the section at the head and round each cord in turn and brought out at the tail [**1** C]. The first sheet is then sewn from tail to head in the same way, and the silk is tied to the loose end hanging from the endpaper. Another section is sewn on and the needle is inserted between the previous sections and catches up the silk that joins them; this is called a *kettle stitch*. The remaining sections and endpaper are sewn on in the same way, the silk being fastened off at the last kettle stitch with a double knot. The cords are loosened, by lowering the crossbar, and are cut off about 3 in. from the book; the loose ends are then frayed out with a bodkin.

If the book is to be sewn on tapes, the tapes are set up on the sewing frame as with cords. The sewing is done as described above, with the exception that, owing to the width of the tape, the thread passes out and back into the section again at different points instead of passing out and in at the same point as with cord sewing [**1** D].

Gluing Up, Rounding and Backing. The book is placed in the press with a piece of millboard on each side, and the back is glued. When the glue has set the book is laid down on its side and half of the back is rounded over with a hammer, it is then turned over and the other half rounded.

Backing is sharply emphasising part of the swelling caused by the thread used in sewing, by compressing the book near the back and beating the back of the sections, one over the other, making a sharp ridge against which the cover will lie. Placed between a pair of backing boards with the back projecting slightly above the boards, the book is lowered into the lying press. With a hammer the sections are then beaten one over the other, starting from the centre and going over equally on either side. The two outside sections are well beaten over the backing boards, for this makes a sharp groove for the boards to fit [**19**].



19. BACKING

Preparing and Attaching the Boards. The best material for the boards is millboard owing to its toughness and thin substance. Two pieces are cut with the millboard shears about a quarter of an inch larger all round than the book. The edges that are to go to the back of the book are then cut smooth in the lying press with the plough. The boards are screwed up in the press with the amount that has to be cut off projecting above the bed of the press. The knife in the plough travels backwards and forwards level with the bed of the press, and whatever projects is cut off.

The boards are then each lined on one side with a piece of white paper pasted on. Two other pieces of paper, double the size, are pasted and the boards covered with these on both sides. The extra lining of paper on one side will cause the board to warp that way, and this side will be placed against the book to counteract the pull of the leather which will ultimately be pasted on the other side of the cover.

The boards when dry are cut to the size required, with the press and plough, and are then attached to the book. One board is laid in position on the book and a line is drawn on the board from tail to head about half an inch from the back. Lines are then drawn from the cords to this line. On these cross lines small V-shaped pieces are cut out of the boards to allow the cords to sink in level when laced, and holes are punched with a bodkin at the points where the lines meet. The boards are then turned over and holes are punched about half an inch from the previous ones. To attach the boards the slips are pasted and passed through the holes first made and then back through the other holes. They are then drawn tight, tapped with the hammer to fix them, and the ends cut off level with the boards.

If the book is sewn on tapes the selvedge of the tape is cut off and the tape can then be frayed out and interlaced, like a cord. When both boards are attached the book is put in the lying press, with the back projecting slightly; it is then pasted to moisten the glue on the surface, which is scraped off with a folder. The cords are nipped up and straightened with the band-nippers, tins are put on both sides of the boards, well up to the groove, and the book is left in the standing press, tightly screwed up, for about twelve hours. The knocking-down iron is then screwed up in the press, and the slips hammered down until they are impressed level with the board.

To cut the top edge the book is screwed up in the lying press with the back to the worker, the front board being lowered just the distance required for the "square," and the edge is cut with the plough [**15**]. The tail is next cut in the same manner.

For cutting the fore-edge the edge has first to be made flat by inserting trindles [**5**] between the book and the boards across the back. A cutting board is placed on each side and held in place while the trindles are removed. The book is then lowered, with the boards hanging down, into the press and the edge cut with the plough.

Gilding Edges. The back is knocked flat, and a cutting board placed on either side of the leaves, level with the fore-edge, and the book is placed in the press. The edge is scraped and finely sandpapered. A paste, made of powdered red chalk and water, is applied to the edge with a sponge and polished with a hard brush. The edge is then painted with a preparation of the white of an egg,

beaten up and diluted with water, called *glaire*. The gold leaf is cut into strips the width of the edge and applied to the edge with a soft flat brush. The book is left to dry and the edge finally burnished with a flat bloodstone burnisher. The other edges are gilt in a similar manner. The edges can also be stained. Water stains answer the purpose, and are applied to the edge with a soft brush, the edges being afterwards burnished with an agate burnisher.

Headbanding. Headbanding is the stitching on the head and tail of a strip of vellum, gut, or cord, to make a similar projection from the back as is made by the boards projecting beyond the edges of the book. As a book is usually pulled out of the bookshelf by the headband, it is important that this should be firmly attached to the book, and one that is made on the book is far preferable to one bought ready-made and stuck on.

The boards are lowered level with the edge of the book held in the lying press or plough, and a needle, threaded with silk, is passed into the edge and out at the back below the kettle stitch. Half the silk is drawn through, and then the needle is again inserted and drawn out. The silk now has made a loop into which a strip of vellum, slightly narrower than the "squares," and a little longer than the width of the book, is placed. The silk is drawn tight and a pin inserted in the edge at the left-hand side, behind the vellum, to keep it in position. The needle end of the silk is brought over the vellum and the other end crosses it and goes behind. This end is then brought over and is crossed by the needle end. The headbanding is continued in the same manner, being fastened down to the book about every quarter-inch. To do this when the needle end is at the back, it is brought over the vellum and inserted into the book and out at the back, and the headband is then proceeded with as above. To finish it off, the needle end is inserted into the book twice, and the other end then pressed behind, and both are cut off, leaving short ends, which are frayed out and pasted down to the back. The ends of the vellum are then cut off.

This kind of headband would be too expensive for the cheaper bindings. In their place the leather at head and tail can be turned over a piece of string when covering.

Leather for Bindings. Various kinds of skins are used in bookbinding, chief among them being those of sheep, oxen, calves, goats, and pigs. *Sheep skins* are cheap, and, when not subjected to hard wear, last well. Those classes of skins tanned in India, and known as "Persians," both sheep and goat, have little durability. *Calf skin*, although capable of receiving a beautiful finish, does not wear well. *Ox hide* has to be reduced so much in substance to be fit for binding books that the greater part of its strength is lost. *Goat skins* furnish "Morocco" leather of several kinds. Of these, the finest is that of the Cape of Good Hope, known when finished as "Levant Cape Goat"; it has a bold, natural grain, and is perhaps the most beautiful leather for bookbinding. *Pig skin* is very durable, and is best adapted for large work. A leather which has great beauty and strength is made from the Greenland seal, but much depends on its preparation.

In cutting out the leather a piece of paper is first cut to the size of the leather required, and the leather is then cut to the size of the paper. The leather requires thinning (termed *paring*) in several places: (1) where it is turned in, to enable it to turn neatly over the edges of the boards; (2) where it will go over the back, to allow the cords to be sharply emphasised; and (3) where it will go in the joints, to enable the boards to open freely.

As there is a double thickness of leather where it is turned in on the back, it is pared especially thin there. The cover is marked in pencil to show where the paring is required, and is laid on a smooth stone and pared with a knife to the necessary degree of thinness.

Covering the Book. Before covering, the edges of the book are "capped up" to prevent damage from the paste used in the process. Two pieces of thin celluloid are placed on either side of the book itself, which is then completely covered up with paper. Small pieces are next cut from the back corners of the boards to allow for the leather being turned in there.

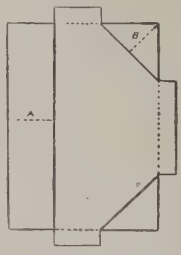
The leather is well pasted, the book, closed, is laid down in the place marked for it, and the remainder of the cover is drawn over the back and the other side. The book is then stood on its fore-edge, and the leather pressed from the back towards the fore-edge. The leather is slightly damped on the back with water, and the bands are nipped up with band-nippers. The cover is next smoothed on the sides and the leather is turned in over the fore-edges of the boards and smoothed down with the folder; finally, the cover is turned in at the head and tail.

At the corners the leather meets at an angle of 45°, and the surplus is cut off with scissors just above the board, and one edge of the leather is lapped over the other. A piece of thread is now tied tightly along the joints passing across the head and tail, and pressing the leather in where the back corners of the board have been cut away.

The bands are again nipped up, and the leather between the bands well rubbed down with a band stick. Finally, the cover is sponged over with water to remove any paste that may have got on the book, and, with a piece of paper on each side, the book is placed between a pair of pressing boards and left for at least twelve hours. When the leather is set, though not actually dry, it is trimmed on the inside of each board.

Half Binding. If the book is to be half bound, the processes are just the same up to covering, and then only the back, about one-third of the sides, and the corners are covered with leather.

The proportion between the back, corners, and the remainder of the sides can be seen in 20. The dotted lines A and B should be of the same length. When dry, the leather is trimmed straight at the back and corners, and the material for the side is cut out. This is usually either paper, cloth, or buckram. It is cut to the shape shown in 20, and then glued on, the edges being turned in over the edge of the boards. With the cheaper bindings, the corners are sometimes omitted, and it is then called a quarter binding.



20. HALF BINDING

Pasting Down Endpapers. The waste sheet is torn out and any pieces that remain in the joint are removed with a knife. The inside edge of the board is then sandpapered or scraped with a knife to remove any glue or paste that may have adhered. The width of the margin of the leather is then taken with a pair of dividers, the pasting-down paper drawn over the board, and the measurement marked off all round on the paper. A tin is then placed on the book and the paper laid down on this, cut round with a knife, and pasted down on the

board. It is rubbed down through a piece of waste paper, particular attention being paid to the joint.

Finishing and Decorating. *Tooling* is the usual method adopted for the decoration of leather bindings. It is divided into two classes —"gold tooling" and "blind tooling." Finishing tools are made in either brass or steel, and have surfaces cut in the forms of lines, dots, or engraved with pattern [12]. For long lines a fillet is used. This is a wheel with an edge cut to the thickness of the line required [7].

If an elaborate pattern is required, a thin, tough paper is used for a working pattern, slightly pasted at the corners, and placed in position on the cover. Then all the tools of which the pattern is made up are heated and stamped in through the paper. A pad of wet cotton-wool is kept close by, and the tools are used when they just cease to hiss on the wool. They are held in the right hand, and when striking, the tool is guided into its place with the thumbnail of the left hand.

If the pattern is to be in blind tooling, the leather is damped and the tools again stamped in. The heated tool coming in contact with the damp leather makes a rich, dark impression.

If the pattern is to be in gold, the leather is washed with vinegar, and when dry, the impressions are painted with glaire, very slightly diluted with vinegar. When the glaire is dry, the gold leaf is cut into pieces of a convenient size to lay on, the leather is slightly greased with a piece of cotton-wool and vaseline, and the gold is picked up with another piece of wool and laid on the pattern and firmly pressed down. The pattern should be clearly seen through the gold, and the tools are now stamped in again. When all the pattern has been impressed, the surplus gold is rubbed off, leaving just the gilded impressions of the tools.

The book is then placed in the press, with tins on the inside of the boards, and nickel plates on the outside, and slight pressure is applied; this causes the boards to close properly, and completes the binding of the book.

PUBLISHING

The publishing of books is admittedly one of the most attractive trades to which a young man can turn his attention. Even old men are tempted to set up as publishers by the general notion that it is about the most lucrative business in which one may engage. This latter is, now, a mistaken idea, whatever reason there may have been for it in the past, and certainly a review of the fortunes made in publishing would go far to support the proposition that it is a paying business. The shrewd Scotsman who founded the house of Murray in the year 1768 had been in the Navy, and was induced to turn publisher because he observed "many blockheads" were then "making fortunes" in that very pleasant occupation. Modern competition has long since made it impossible for any but the most resourceful of men to succeed in the world of publishing, and only a few businesses, which exist very largely on their old reputations, can be conducted on the easy methods of half a century ago. There is undoubtedly no room for blockheads today. In point of fact, after newspaper publishing, there are few businesses in which one can more speedily get rid of a considerable fortune than in book-publishing. To secure any substantial success, a large capital investment is absolutely essential, and this none the less when it is associated with brains and intimate knowledge of the trade.

Value of an "All-round" Experience. There is, of course, a "royal road" to publishing as to most other trades, although our moralisers may deny this. But few of us are in the position to follow the royal road, and have, instead, to take the toilsome way which, in the end, is likely to be more solidly successful, and may, on the whole, by honest endeavour, be made as pleasant. If we cannot, by paying a substantial fee to some publisher for the privilege of receiving an insight into all his departments—as so many Germans used to do in London—we must needs begin at the bottom of the ladder. Naturally, the earlier one enters the trade the better. We know one of the most successful of the younger publishers who practically went through every department, beginning as a shop-lad in a large wholesale firm of distributors, with his mind constantly set on becoming a book-publisher. As he had realised his ambition before he was thirty, it will be seen that, given sufficient pertinacity and resource, even the humble shop-lad may look forward to seeing his name as the imprint of thousands of books some day.

In all the leading provincial cities there are large firms of wholesale dealers in any one of which invaluable experience may be obtained, provided always that one enters their service early enough—say, from fourteen to sixteen years of age. By passing through the various departments in a large wholesale house, the Town Department, the Country, the Postal, the Stock, and other departments, a thorough knowledge of a most important side of the publishing business may be obtained. One might come somewhat later to the wholesale trade, if one had previously secured some experience in a retail booksellers' [see BOOKSELLING, page 4453], and, indeed, this would be a wise course to pursue.

The Producing of Books. But after everything has been learned, both in the wholesale and retail, there would still remain the most important knowledge of all to be acquired—namely, the manufacture of books. The bookseller and the wholesaler only come in after the publisher has done his work. It is by no means usual that one man should have experience in every detail of the trade from the producing to the selling of books, and in every publishing house in the country there are many employees who have served for years, and are content to serve, in some particular department without acquiring a general knowledge of the trade. Indeed, such men necessarily form a majority of those engaged in the business, but it is not from such that successful publishers are made, and nothing is more fatal to promotion than remaining too long in any one department.

Before turning to the consideration of the actual business of a publisher, we should point out that most valuable experience can be obtained by engaging as traveller with a wholesale house. Of course, every publishing firm of any standing employs a number of travellers from whose ranks many of our most successful publishers have risen. We have preferred to mention the great wholesale houses first, as these are not confined to London, whereas, excepting a few notable firms in Edinburgh and Glasgow, there are practically no important publishing houses outside of London. The provincial youth has thus to turn his attention—in the first place, at least—to the wholesale distributors and the large booksellers, who very often do a small amount of original publishing.

London is essentially the Mecca of publishing, and the young man who is ambitious of becoming a

publisher will do well if he can secure an engagement with a London publisher when he is about twenty years of age.

The Young Publisher's Progress. Assuming that he is determined to be no mere employee in a department, but has set his mind on a managerial post at least, we shall suppose him to have had, first of all, a reasonable knowledge of English literature [see LITERATURE], and if he gives evidence of any literary taste and judgment, he will not find it difficult, after he has spent some time in the Costing Department, where he will have become familiar with the cost of producing a book and the various qualities of material used, in getting into the Production Department, the scope of which varies greatly in accordance with the importance of the firm. Here the duties consist of keeping account of all accepted MSS., arranging with the printers for specimen pages, and estimating the size of books, deciding upon the style of title-pages, bindings, general get-up, and proof reading. It is, in a word, the department in which all the practical detail of production occurs, from which the MS. of a book is handed to the printer, and from which the first completed book is handed over to the manager. In the smaller firms this department is concerned also with drawing up the spring and autumn catalogues, but in the large houses that important part of a publisher's business usually falls to the lot of the Publicity Department.

It will be gathered from our qualifying references that it is very difficult to speak of the publishing trade in general terms. There are many publishers earning a good livelihood who employ no more than half-a-dozen assistants, and unite in themselves all the different departments we have mentioned. In fact, it is no bad plan for a young man to attach himself to one of these smaller publishers, as the variety of work which will fall to his share every day will result in his acquiring a very good knowledge of the trade more speedily than it could be acquired in one of the larger firms.

The Work of the "Literary Adviser." The office routine of a large publishing house is, of course, very much the same as that of any other business, but the young man who has shown sufficient literary aptitude to be placed in the Production Department is fairly certain to be employed sooner or later in the reading of MSS., and in consultation with the manager preliminary to the acceptance of a work. The "literary adviser" used to be a somewhat mysterious person who read all the MSS. received, and supplied reports as to their literary qualities and the likelihood of their success. He was sometimes himself a distinguished novelist, who thus eked out some extra income by giving what was very frequently the most misleading advice. This old-fashioned type of adviser is disappearing. The successful publisher of to-day depends hardly at all upon the unsolicited MSS. he receives. They are read and reported on as of old, but his reader, if he himself does not do the work, is more likely to be some alert person with the real journalist's knowledge of what is calculated to interest the public, and it will be found that he or the publisher himself will be the first to think of most of the books they will publish. As a matter of fact, the ideal publisher, or literary adviser, is essentially an ideal editor. The editor of a successful magazine has a certain public, or perhaps several publics, in mind when he sits down to plan out his next number. In order to secure an attractive programme, he will ask a certain number of distinguished writers each to contribute a story of a certain kind and a given length. He will arrange so many articles to suit this section or that section of his readers, and he will ask certain writers to prepare them. He will then decide how many pages each is to occupy, including illustrations, and will carefully choose the artist who can best do the different kinds of pictures he requires. Hence, although he may receive 200 MSS. per week, he will seldom retain more than two, and nothing but the fear of missing a good article by an unknown writer induces him to wade through the MSS. Now, if for stories and articles we substitute novels and books of biography, travel, and general literature, the publisher is engaged in precisely the same work as the editor. This indicates that one may come to publishing through editing; but, of course, for such a one the SELF-EDUCATOR is hardly likely to be a guide.

"A Genius for Publishing." It is unnecessary here to dwell upon such technical details as the arrangement of a book, the various sizes of paper, types, illustrations, printing, and book-binding. All these matters are dealt with in other parts of the present course, and with them the beginner in book production must necessarily and speedily familiarise himself. In the little space that remains to us we must confine ourselves to the general aspects of publishing, and need we say that after every possible tittle of information touching the practical side of the business has been acquired, if the intending publisher is not gifted with the peculiar acumen that makes the successful editor and the prosperous publisher, he may have studied and prepared for the work in vain? There is some touch of genius in knowing just what is likely to meet the tastes of the many different sections of the public, and without this all the technical knowledge in the world will avail nothing. Every day of our life we see books being published which we know cannot possibly succeed. Sometimes this is the bad judgment of the publisher; again, it may be the foolishness of the vain writer, who has paid some publisher to issue the work, but publishers who do this never rank high in the profession.

Risky Publishing and Safe. Not very well can we lay down any rule as to the amount of capital that is required to engage in publishing. Everything will depend upon one's personal requirements and how soon a return for one's money will be expected. This, however, can be said, that cheap publishing requires by far the largest amount of capital. That is to say, to deal largely in attractive editions of non-copyright books at cheap prices involves a much greater risk than the publishing of original works in general literature, in editions of, say, one thousand copies, at good prices, from six shillings upwards; and if the possibilities of the more expensive publishing are not quite so great, the money invested is far safer and likely to produce a substantial return. Novels, and fiction of all kinds, involve a much greater element of risk than works of biography and travel; but it is an axiom of the trade that educational and technical books are of all the most desirable to publish, as they supply a demand that can be easily gauged, and if at all well done, cannot easily fail to be profitable.

PRINTING CONCLUDED—END OF GROUP 9

From Cadet to Admiral. Entrance Examination. Naval Colleges. Course of Training. Special Entry Cadets. Pay and Promotion. The Royal Marines.

THE NAVAL OFFICER

We have shown how a seaman may rise in the Navy from a second-class boy to commissioned rank; we shall now proceed to explain how a boy more favoured with Fortune's blessings rises from midshipman to Admiral of the Fleet. It will be observed that we deal in this section only with the executive branch of the Service, the Paymaster branch being dealt with in the Civil Service group on page 2573.

Efficiency of the Naval Officer. Today the cry of the Navy, as in every other profession, is for the life-trained officer, for there is so much to learn in our complicated floating boxes of machinery that to know even a part means a life study. For a man who is to lead men, also, the training in the habit of obedience and discipline cannot begin too early. In the case of other Services, charges are sometimes levelled that the training methods are inefficient, and that the living is extravagant. This, however, cannot be said of the Navy, where the keynote of naval education is thoroughness, and where economy of living is the watchword. From the moment a boy joins the training college as a naval cadet he is taught that strict attention to work is the only avenue to promotion; and his allowance of pocket-money would compare badly with that of a public school boy of his own age. After reaching the rank of lieutenant a young man can live fairly comfortably on his pay.

It must be understood that at present the representatives of two systems of education are working side by side in the Navy. Under the old system boys entered for whatever branch of the Service they fancied—executive, engineers, or Royal Marines. The result was a race of specialists—each man excellent in his own department, but knowing very little about the work of other branches of the Service. To remedy this state of things a new system has been introduced to produce a type of officer with a more comprehensive knowledge and wider sympathies. The age of entry is now between 13 years 4 months and 13 years 8 months, so that today a boy must decide practically on leaving his preparatory school that he desires to enter the Navy. The new scheme, however, is still to some extent upon its trial, and will probably be modified again as the outcome of the lessons of the great war.

The Preliminary Examination. The training begins at Osborne College. To be admitted, a boy must be of pure European descent, and the son of natural-born British subjects, or of parents naturalised in the United Kingdom. An application for appointment should be addressed to the assistant private secretary of the First Lord of the Admiralty, and should not be made before the boy is 12½ years old. On receiving a notice from the First Lord, the candidate is required to present himself before a committee, not for an examination of his book knowledge, but so that the committee may have an opportunity of judging from his conversation and manner what sort of a boy he is, and whether he is likely to make a good officer when he is grown up. The candidate is required to produce a certificate of birth (or its equivalent), a certificate of good conduct from the master of the school or schools at which he has been educated for the previous two years, and proofs of good health and freedom from constitutional disease or hereditary taint of any kind. A severe medical inquiry has to be faced, and then the qualifying examination, which embraces the following subjects:

English: Dictation, simple composition, and reproduction of the gist of a passage read twice by the examiner.

History and Geography: The whole outline, with special reference to the British Empire.

Mathematics: Arithmetic (simple), including decimals, fractions, mensuration of area and capacity, money, proportion, etc. Algebra, up to simple and simultaneous equations. Practical geometry (angles and construction of angles, squares, parallelograms, and division of straight lines into equal parts). Theoretical geometry (angles at a point, parallel lines, triangles and other rectilinear figures, areas, and loci).

French or German: Simple examination, with great stress on the *vivâ voce* part.

Latin: Easy passages for translation, English-Latin and Latin-English, and simple grammatical questions.

Specimen examination papers can be obtained.

Cost of Training. This examination successfully passed, the lads have to present themselves in uniform at Portsmouth Dockyard on the appointed day, and are taken across to Osborne by a Government launch. Here the foundation of their life-work is laid.

Beyond the cost of the kit, which consists of bed-linen and towels as well as clothes, the cost to the parent is at the rate of £75 per annum in three (advance) instalments of £25. Over and above this, to cover the miscellaneous expenses, such as washing, instruments, books, sports, and pocket-money, another £8 per term should be expended. In a few cases the Admiralty allow the sons of officers in the Army, Navy, or Civil Servants under the Admiralty to enter at a reduced payment of £40 a year.

Osborne College. The Naval School at Osborne is organised on the lines of the best public schools, special attention being directed to fit the cadet for his career, not only as a skilful seaman, but also as an officer and a gentleman. Examinations are held at the end of every term; and should a cadet fail to satisfy the Lords of the Admiralty his parents may be asked to withdraw him at any time. A declaration of willingness to do this has to be signed at the time of the boy's joining, together with a declaration of willingness that the boy shall enter that branch of the Service for which he may seem to be best fitted, whether engineering, Marine, or general executive. At Osborne a splendid workshop has been fitted up,

and the cadets spend quite half of their time in practical and theoretical work connected with engineering or in studies closely bearing upon it. Physical education and seamanship are also well looked after.

Dartmouth College. After two years the cadet passes on to Dartmouth College for another two years, to complete his preliminary studies. The course of this four years' training includes the study of mathematics, mechanics, heat and electricity, the theory and practice of engineering; English and French composition and literature; history and geography, navigation, and the elements of seamanship; religious knowledge; and physical education. In his first summer at Dartmouth he and his colleagues pay a visit to Devonport in a torpedo-boat destroyer, which they have to drive and steer. On leaving Dartmouth he goes to a training cruiser for more practical instruction in navigation, seamanship, and engineering than can be obtained ashore. Until he reaches the rank of acting sub-lieutenant his parents are required to make him an allowance of £50 a year, and thereafter £20 a year until he becomes a sub-lieutenant.

Midshipman. At the end of six months on the training cruiser he is drafted with a batch of youngsters of his own seniority to a sea-going ship as midshipman. This, however, does not mean that his education is complete. True, he is no longer under a civilian instructor, but he devotes his whole time to learning his professional duties under one or other of the officers, about one-third of his days being spent in the engineering section. On completing three years' service as a midshipman a serious examination has to be passed for acting sub-lieutenant in seamanship and practical engineering. He attends the next examination in navigation and general subjects, and he attends short courses on gunnery, torpedo work, and pilotage at the depots, each of which is followed by an examination on the work studied in the course. Those who show aptitude and special ability are then allowed to go through a further and more comprehensive course, lasting six months, at Greenwich Naval College, which fits them for specialising in any particular branch.

The sub-lieutenants who do not qualify for the extra course are immediately sent to sea, and are joined by the Greenwich students at the completion of their course. Sub-lieutenants must serve at sea for at least one year before being promoted to lieutenant, and must obtain from their captain a certificate that they are efficient in the duties of officers of the watch.

"Special Entry" Cadets. Although the Osborne and Dartmouth course remains the normal means of entry into the Royal Navy, a supplementary scheme has been introduced in consequence of the war, enabling at least sixty lads yearly to become cadets between the ages of 17½ and 18½, and to reach the rank of midshipman after only 1½ years' training. These "special entry" candidates are selected precisely like the rest, save for the higher age limits and an entrance examination which is correspondingly severe. On passing the latter they undergo a course of instruction which lasts for eighteen months, being quartered meanwhile on board a cruiser, but spending part of their working time on shore. On completing this course they join the fleet as midshipmen, and, after less than two years in that rating, are eligible for promotion to that of acting sub-lieutenant. The result of these shortened terms of service is that a "special entry" cadet

RATE OF PAY OF ALL RANKS OF OFFICERS IN THE NAVY

Rank.	Per Annum.	One Day.	Special Remarks.
	£ s. d.	£ s. d.	
Admiral of the Fleet	2190 0 0	6 0 0	With table money varying between £547 10s. and £1642, according to station and the amount of entertaining required.
Admiral	1825 0 0	5 0 0

NOTE.—In R.M.L.I. the rates are slightly less in all ranks.

they become acting sub-lieutenants, and then of £20 a year for the time (usually only about two months) that they remain in this rank; but no college fee need be paid for their training.

Lieutenants. Under the new scheme of education, the dividing line between general and special training is crossed about a year after promotion to a lieutenancy. At this point the lads, who have all been trained under much the same system, are now apportioned to the branch for which they are most fitted, and the most capable among them become specialists in engineering, in gunnery, torpedo, or navigation, being denoted by the letters E, G, T, and N, while some go to the Marines, whom we shall call M. Each undergoes further training to equip him for his particular duties—the gunnery officer going to Portsmouth, the navigation expert to Greenwich Naval College, and so on. Lieutenants (M) go to one of the Marine divisions to learn their special military work. The rest become general service lieutenants, popularly known as "salt-horse lieutenants," who are available specially for watch-keeping, discipline, and seamanship.

Of these specialists a few of the best are allowed a further course of instruction to fit them for a higher grade of lieutenant, which, for the sake of clearness, will be called G 2, T 2, and E 2. For these the higher course lasts for one or two years. Of the general service lieutenants a few are selected for instructional purposes, and undergo a short course to fit them for their work. Not only is promotion speedier for the specialist officer than for his less brilliant or less hard-working colleagues of the "salt-horse" class, but he earns higher pay or extra allowances in each rank.

Branches of the Service. Now it has been explained how the lads trained together in the same system as far as the rank of lieutenant have been broken up into three main divisions—engineers, Marines, and what we shall call, for want of a better term, general executive officers, which divisions have been subdivided into specialists and non-specialists. It remains to be shown what these young men will do with their careers. Will the specialists continue as specialists to the end of their days, or do they foster the hope of one day commanding a fleet?—for it is still open to the engineer to revert to the main channel and go through the ordinary course of promotion.

In exceptional cases, it is possible for the lieutenant (E 2) to revert, but it is most unusual, and indeed, undesirable, for he is throwing away his special education and his chance of quicker promotion. He will therefore look to the engineer branch to provide his fortune, and he will rise in the ordinary course to commander (E 2), captain (E 2). And although he will go to sea from time to time to keep in touch with modern practical engineering, the Admiralty will be glad to make use of his services ashore and in the higher ranks of the dockyard advisers. The Marine lieutenant, in some cases, will revert to the general executive, and be appointed commander in his proper turn; for not only today is he the musketry officer, but he can also take his turn in watchkeeping and the general duties of the ship. On the other hand, he may qualify for commander (M), and then revert to captain in command of a ship. A third possibility, of which a few will avail themselves, is to continue discharging the duties of Marine commander, and look for promotion in the Marines through the ranks of captain (M), major (M), and colonel to general.

The Ladder of Promotion. For the rest, the general service lieutenants, there is a long, weary wait for their next step. After five years' service in the rank the officer has to pass an examination in naval law, court-martial, naval history, strategy and tactics, besides the examination in the general professional subjects. In due course his turn for promotion comes, and he is promoted to commander, probably in ten or twelve years. It must not be supposed that the time has been monotonously spent. He has been changing from ship to ship, has been in torpedo-boats, destroyers, cruisers, and battleships, and has served at home and abroad. He has attended qualifying and re-qualifying courses, and has every year been learning something of the management of ships, of guns, and of men. So that at about the age of thirty-five he is a man of wide knowledge and experience, besides having passed about twenty severe examinations. Another four to six years as commander should see him promoted to captain, if he is fortunate, though still he has not completed his education, but must go to Greenwich to learn the higher teachings of strategy. In the end he is promoted at last to admiral after eleven to fifteen years in command of ships.

The Royal Marines. We have seen how this, like any other branch of the naval service, may be chosen by the ex-cadet from Osborne and Dartmouth who shows sufficient ability. But a certain number of commissions in the Royal Marines are awarded to candidates from outside the naval colleges. Competitive examinations similar to those for entering Woolwich are held among youths between 17 and 19 who have satisfied the interview committee. Successful competitors are sent to the Greenwich Naval College, and take special courses in gunnery, torpedo work, and military duties, and are also required to serve afloat. After a period of nearly five years' training, they are subjected to a final examination, on passing which they rank as lieutenants in the Royal Marines. They usually remain in that corps, although a transfer is possible for them, as for the ex-Dartmouth officer who has taken up the Marines' duties, from the "sea-soldiers" to the purely naval branch.

Exhibitions and Demonstrations. Sampling Schemes. Railway, Omnibus, and Tramway-car Advertising. Showcards and Posters.

MISCELLANEOUS ADVERTISING

NEWSPAPER and poster advertising brings the name of an article or product before the public, but there are various forms of publicity that go farther than this, and bring the actual product either before the immediate notice or into the very hands of the people. Such methods of direct advertising are in great and growing favour among manufacturers and shopkeepers, and they certainly get as near to ensuring sales as it is possible for any advertising to do. These methods place the article right into the hands or the homes of the people; and if the public do not then become customers, it is because the article is not good enough, is not wanted, or is not sufficiently better than a rival article that is well established. Advertising can go no farther than this.

Exhibitions. Among these forms of publicity, the first to be considered is that which is effected by means of exhibitions. Here, under favourable conditions and in circumstances that certainly help to attract and to hold the attention of the spectators, goods are displayed with even greater advantage than in a shop window. Every trick of colour and artificial lighting may be utilised; the visitors come for no other reason than to look at things and to be interested in them, and one has opportunities of speaking to people and commending one's goods to them that do not occur on so extensive a scale in any shop or store.

Various Kinds of Exhibitions. Of course, exhibitions are of various classes and kinds. Some are intended frankly and primarily as places of amusement, to which the public can go for entertainment. Others are intended to be educational; and while there may be attractions of the purely entertaining class, yet instruction is the prime object of the exhibition. Then there are trade exhibitions the object of which is to attract the shopkeeper or merchant, and to get from him on the spot an order for the goods he sees. The public, of course, visit these shows to a limited extent, but it is the trader who is primarily concerned. The big foreign expositions must not be neglected, these, of course, being of interest only to firms that do or wish to do an export business. At the opposite extreme are the small local exhibitions, scarcely heard of outside their own immediate neighbourhoods, but which are nevertheless often of great use from the advertising point of view to the manufacturer, merchant, and shopkeeper. Still another kind of exhibition, known as a Trade Syndicate Exhibition, combines to a certain extent the amusement, the instruction, and the trade benefits of the larger exhibitions referred to.

Trade Exhibitions. Trade exhibitions are a recognised feature of the business life of the country, and many manufacturing firms spend a great deal of their appropriation in making use of these exhibitions. There are various firms who make it their business to organise and finance trade exhibitions; and while this is sometimes done quite independently of all trade organisations, the usual method is to secure the active patronage of the local trade association.

In consultation with the association, a date is arranged and a hall taken, and it is then the business of the promoting company to approach the big manufacturers connected with the particular trade, to induce them to take space and make a good show. It is from the rentals thus secured that the promoters pay the expenses of the exhibition and make their profits. If the trade patronises it well, spaces let at remunerative rates, and often a handsome profit results; but if the trade fights shy, rent-prices have to be cut, a heavy loss is made, and sometimes the promoting company goes bankrupt. There are, however, in the country, several companies of the kind indicated who have for years past been extremely successful in organising and conducting trade exhibitions; and when their names appear as the directors of an exhibition the trade as a whole shows great confidence, and success is pretty well assured to all concerned.

Obtaining Exhibitors. The method by which exhibitors are secured is as follows. The promoters write round to all the large manufacturers and wholesalers, enclosing them particulars of the proposed exhibition, the hall it is to be held in, the date, the attractions, such as military bands, etc., together with a plan showing the blocks or spaces available, with their prices and dimensions. With the communication goes a form of application which, when filled up, would read something like this: "To Messrs. Brown & Jones, 50b, the Grove, Liverpool. Gentlemen,—I hereby request you to allot me space as set forth below for the exhibition of [here the proposed exhibits must be fully described]. The space is marked 14, and is in the block A on the plan, and the measurement is 16 ft. frontage by 10 ft. side space; total, 160 square ft. For this I agree to pay 2s. 6d. per square foot; total, £20. Deposit £5 is sent herewith, being 25 per cent. of the total amount of rental. This application is subject to the General Regulations and Conditions set forth herein, which I agree to observe."

Conditions for Exhibitors. The regulations and conditions are always set out in great detail, and it is important that an exhibitor should read them most carefully and understand them fully. Summarised, they may be set forth thus: Any variations of the conditions, unless in writing and agreed to and signed by an authorised agent of the exhibition company, shall not be binding upon them. The plan of the exhibition is to be taken in conjunction with the application form, and this is to have the space let marked on it. All contracts for space, etc., are subject to the requirements and conditions of the superior landlords, local and administrative bodies, and guarantee and insurance companies, and all or any having authority through ownership, law, or contract. This is important, because sometimes the catering arrangements of a hall are permanently in the hands of a firm of contractors, and this may prevent a food or drink firm demonstrating and selling its goods.

The exhibition has to be opened on the date fixed by the directors, and it has to remain open on

the days and during the hours advertised. There is, usually, however, a special condition qualifying this by adding that the dates will be kept "unless unforeseen circumstances arise." This clause proved extremely useful to several promoters of exhibitions in 1914, when the great war broke out and their halls were commandeered by the military authorities. Admittance is by ticket, and only tickets issued by the promoting directors are accepted. If by fire, storm, or tempest, riot, etc., or any other cause, the hall or building be destroyed or damaged so as not to be available for the holding of the exhibition, or if for any other unforeseen circumstance the promoters cannot get possession of the hall, then they are not responsible to the exhibitors for loss, delay, expense, or damage, except for the return of the deposit money paid on application for space.

Space must not be sub-let, divided, or held in joint use without the consent of the directors; and if a space is not occupied one clear day before the opening of the exhibition in a satisfactory manner, and in accordance with the purpose for which it was let, then it is forfeit, and the directors may re-let it. This, of course, is necessary, so that the exhibition when it opens may be ready and complete. Stands have to be erected, filled, and removed at the expense of the exhibitors during a specified time decided by the directors, and they must not be removed before the exhibition has closed. All designs for stands are subject to the approval of the directors. This is a very necessary condition, as exhibitors might be putting up small and insignificant stands on large spaces, and the whole exhibition would suffer on account of a mean appearance. Any encroachment on gangways and passages is regarded as a breach of agreement, and this applies to overhead signs, flags, etc., as well as to goods standing on the floor or platform. The directors, however, are always ready to give permission for signs and flags that will not cause any obstruction to other stands or in any other way be an annoyance to exhibitors or visitors.

The directors usually appoint advertising agents, photographers, insurance brokers, stand fitters, and firms to supply power, lighting, heating, and water, and no persons other than those thus appointed are allowed to canvass exhibitors or do work in connection with the exhibition unless, of course, they obtain permission of the directors. This restriction does not, however, apply to exhibitors who employ members of their own staff to do such work as stand-fitting, and so on, but those workers are bound by the conditions imposed upon official contractors.

Delivery of Exhibits. All goods for the exhibition usually have to be delivered at the hall not later than the morning of the day preceding that of the opening. The exhibits must be properly arranged and displayed in time for the opening, and must remain displayed throughout. Perishable goods may, of course, be removed and renewed. The directors take no responsibility for damage or loss through fire, water, tempest, exposure, damp, theft, or any other cause, and exhibitors should always insure in order to cover these risks.

Fitting Up the Stands. Every precaution must be taken in fixing up the stands not to damage the fabric of the hall in any way, and if such damage is done the exhibitor has to indemnify the directors in case of a claim on the part of the owners of the hall. Nothing may be attached to the floor, walls, or fixtures by nails or screws without specific authority having been previously obtained. Of course, no dangerous or explosive article may be brought into the hall by an exhibitor without the previous consent of the directors given in writing, and the quantities of any necessary chemicals or oils must be given.

All the cases and packing in which the goods of an exhibitor have been carried to the hall, after being emptied, must be stored out of sight, either somewhere on the space rented or in some other place, such as a cellar, provided by the directors. Tickets, which are non-transferable, are supplied free of cost to admit exhibitors and their workers.

What Exhibitors may and may Not Do. Exhibitors are usually allowed to distribute literature from their stand, and to sell samples and packages, but they must confine their efforts to their own stand, and must do the distribution in such a way as to cause no annoyance to other exhibitors or to the exhibition as a whole, and they must do nothing that will cause the gangways to be blocked inconveniently. This condition, however, is not always an easy one to fulfil when the exhibit is a really attractive one or when an interesting demonstration is going on. No advertising sign may be fixed by an exhibitor in any part of the hall except in his own space without first obtaining permission of the directors; and no musical instrument may be played in the exhibition without such permission. Even when it has been given, as for a gramophone, if it prove an annoyance to others the authorities may request that it be stopped. Care must be taken, too, that in addressing visitors during a demonstration, or in endeavouring to sell samples, there shall be no undue shouting or noise.

Paying for Space. The usual method of paying for the space rented at an exhibition is to send 25 per cent. of the amount with the filled-up application form, and the balance on the day the exhibition opens. If the balance is unpaid when the exhibition opens the directors usually reserve the right to take possession of the space, retain all the goods that may be there, distrain upon them, and sell them in order to pay themselves the money due, together with expenses incurred in doing all this.

These multifarious conditions may seem somewhat irksome when read, but in practice they work out quite well; and it will be obvious to the least thoughtful of persons that, with such a heterogeneous collection of exhibitors and their employees as is found at an exhibition of this kind, the conditions have to be very definitely laid down so that all may distinctly understand their rights, and not overstep them.

Making the Best of a Trade Exhibition. If the best is to be got out of a trade exhibition, the local traveller or representative of the firm exhibiting should be a good deal in attendance in order to meet his friends and take orders. Wherever possible, demonstrations and workings should be given, as a mere dead exhibit has little to sustain the interest. Machinery, vacuum cleaners, and such like apparatus should always be shown working; food products should be made up in full view of the visitors, who should be invited to taste samples; gas and electric light apparatus should be kept burning; and so on. In this way a double result will be achieved—the trader will be attracted, and the members of the general public who happen to visit the exhibition will be interested.

The dressing of the stand is very much like the dressing of a shop window. An experienced dresser is needed if it is to look its best. Framed diplomas and, where foods are concerned, certificates of purity such as those issued by the Incorporated Institute of Hygiene should be prominently displayed. If the exhibitor's works are distinctive, impressive, well situated, or have anything that is peculiarly attractive, large-sized artistic photographs, well framed, should also be exhibited. Such photographs form an excellent screen for a blind side or back of a stall that happens to be exposed. Where the firm holds a Royal appointment, then the Royal Arms, either in metal or embossed on plate-glass, should be prominently exhibited.

Attendants at an Exhibition. A word must be said about the attendants at a trade exhibition. Where women are employed, as in demonstrations, they must be attractive without being flashy, and should be well dressed, though not showily. If the exhibit is one of foodstuffs, the girls, if dressed in light frocks, neat aprons, and stylish, starched white caps, add greatly to he attractiveness of the stall.

The literature for distribution at the stall must depend for its character upon the nature of the exhibit. In the case of a food firm, pamphlets describing the purity of the ingredients used and the cleanliness of the factory where they are prepared should be prominent, and also well-illustrated recipe booklets, giving many ways in which the particular food product in question can be used. If the article is a household one, like a vacuum cleaner, then the literature should contain a full description of its advantages and clear details as to how it should be used. For exhibition purposes cheap leaflets are of little use. The crowd is a more or less selected one, and while cheap printed matter is certain to be thrown away, thereby littering the hall, the better type of pamphlet will probably be carried home.

Sometimes the addresses of visitors may be secured, under the plea that a booklet is to be posted on, and a list of such addresses is always useful for future circularisation through the post.

General Exhibitions. The conditions and regulations for a general exhibition intended primarily for the public and not for the trade are very much the same as those already described. For sampling and demonstrating the same care has to be taken not to infringe the rights of the refreshment contractors of the hall, and, of course, the rules as to what may be an annoyance to neighbouring exhibitors or to the exhibition generally are even more stringent than in the case of the trade exhibition. At some of the smaller public exhibitions arrangements are sometimes come to by which only one firm of a particular trade or class is allowed to show. In such a case the value of the publicity to those firms which exhibit is greatly enhanced, as the absence of rivals concentrates the whole of the attention on the particular goods shown by the single firms admitted. A monopoly of advertising in such circumstances is all for the good. Incidentally, it may be mentioned here that monopoly of publicity is not always to be desired. Many a demand of the public would never have been created at all if the work of creating it by publicity had been left to any one firm. It is the multiplicity and variety of advertising, together with the competition of rival firms, that makes a lasting public demand, and turns what may have been considered a luxury into an absolute necessity. The huge sales of beef extract made by a number of big manufacturers, a demand that has only existed during the past quarter of a century, is a striking instance in point.

Rival Attractions. At a big public exhibition, largely supported by Government authority, the exhibits are generally so good that they render it necessary for the manufacturer of or trader in mere household commodities to make a very large and attractive show if he is to get the attention of visitors at all. A mere dead exhibit, unless it is very prominent indeed, is not likely to be seen by many; and it is important to remember that in a general way, unless a good deal of money is going to be spent in arranging an exhibit at a big public exhibition, it is not worth while to go in at all. A small stand that might be excellent for a trade exhibition or a local show is worse than useless for a large national exhibition like those held from time to time in London or other large cities. By its very insignificance it is apt to give a wrong impression of the firm, the public judging of the relative importance of rival firms very largely by the size and attractiveness of their exhibits.

Distribution of Literature. At these large exhibitions the number of visitors runs into millions, and it is obviously impossible to give to all anything like an adequate supply of the best literature. This renders it necessary that the attendants should be men or women of discretion. Discrimination must be made; and while there may be folders and leaflets for general distribution, the more expensive booklets should either be kept out of sight or in such a position that they have to be asked for. An enormous proportion of the people who visit a big exhibition are on the look-out for something for nothing, but, as a rule, these are the people who are not worth attracting, anyway for a high-class commodity. Anything like dainty booklets with artistic covers should always be enclosed in envelopes, so that the recipients may be able to get them home in a clean condition. A little fingering, in hot weather particularly, will soon spoil the appearance of a dainty booklet, and as a result its appeal is largely lost.

Carrier Bags. Where small goods, foodstuffs, etc., are being sold, carrier bags should be provided, so that customers may carry their purchases away conveniently. These bags are usually made of stout brown paper, with eyelet-holes and string handles, and on the sides are printed the name of the firm, and perhaps a line of advertising or the name of some special proprietary article. The advertisement must not be too blatant, or women will not care to carry the bags, but if the printing is neatly done in a high-class type, then the bags will not only serve the useful purpose for which the customer welcomes them, but they become valuable advertising media too. Such bags, if well and strongly made, are not thrown away when the goods reach home; they are carefully preserved for future use, and often hang in the kitchen as receptacles for string, etc., where the printed name of the firm is a more or less permanent advertisement. A warning must here be given in connection with carrier bags: see that the eyelet-holes are well protected with discs, so that the string does not easily tear away from the bag. It is very irritating to a woman to find, after carrying her bag for half an hour or so, that the string handle comes off, rendering the bag practically useless for its purpose.

Lighting. The artificial lighting of a stand must always be good. Nothing is worse than an inadequate supply of lamps. It is not so much in the quantity of the lamps used as in their illuminating power, and electric lights are generally more suitable than gas. First of all, they throw out less heat, and the heat in an exhibition hall on a warm summer evening, when people are crowding in, is apt to be very oppressive. Anything, therefore, that will lessen this is good, not only for the exhibition as a whole, but for the individual exhibitors also. Very often it is necessary to have some artificial light during the day, as, where a hall has a large expanse of glass roof, blinds are usually hung across to protect the hall from a glaring sun; and, on a dull day, unless these hangings can be removed, the amount of daylight will be quite inadequate. Of course, the stands will always look better when they are well lighted at night by gas or electricity, just as the stage of a theatre is at its best when seen by artificial light, the only conceivable way of seeing it to advantage.

Position of a Stand. Great care must be taken in the selection of a position. It is unwise to get too near the band, for instance, as when this is playing, and the people crowd round, that is naturally the overwhelming attraction, and the backs of the visitors will be turned to the stand, and their faces to the band. The sound of the music, too, will drown the voice of any attendant who may be trying to speak to visitors, or describing a process or article during a demonstration. A position too near the entrance is to be avoided, as when people come into an exhibition at first, they walk on some distance before their minds have become attuned to the idea. What they see first makes very little impression upon them, as they are thinking about getting farther on, so as to obtain a general impression of the exhibition as a whole. For household commodities, at any rate where the desire is to attract the general public, a position near the entrance to lavatories should be avoided.

Then, again, a stand should never be next to another stand belonging to an exhibitor in the same line of business, if it can be avoided. Whenever possible, an exhibitor should see the hall before deciding upon the space he will take, for in addition to the general principles of selection given above, there are various local considerations confined to particular halls—draughts, windows, doors, posts supporting the roof, etc. The latter are often a great nuisance, and may seriously impede access to a stand, or spoil the general effects of its contour. Another consideration that must be taken into account where food or washing demonstrations are to be given is nearness to the water supply, unless, of course, water is to be laid on to the stand. This latter is a considerable expense, and is not always necessary, unless a great deal of water is required continuously.

Importance of Good Attendants. However good a stand may be, and however well the exhibits are displayed, the effect is largely lost unless the attendant is capable. This applies to the general exhibition as well as to a trade exhibition. Of course, in the case of dead exhibits, there is no attendant. The display is merely that of the shop window without the shop, but such methods of utilising exhibitions are not now in much favour. It is felt by most manufacturers that, in addition to showing their goods, they must have a competent representative to emphasise their points, and, incidentally, to take orders. Attendants, whether male or female, should always be well dressed.

Much, of course, depends upon the nature of the exhibit. For dry-goods, a man should wear a morning-coat and spotless linen; for fancy goods, women attendants should be dressed much like the best class of drapers' assistants; for demonstrations of cookery, men should be attired in white, with white caps, like hotel chefs, and women should wear large fancy white aprons and caps. For all domestic exhibits, where the idea is to attract the housewife, it is important that women attendants should give no impression of flashiness. This is a consideration too often overlooked by exhibitors, but it will be understood that any such impression given to lady visitors will naturally prejudice them against the stand and exhibit. The women attendants must, however, be attractive, good-looking if possible, very neat and tidy, and with a pleasant, appealing manner that holds the listener.

Travelling Exhibitions. Another type of exhibition, one which is perhaps of more value to the manufacturer of household commodities and articles than any other, is that of the travelling syndicate exhibition. In this case a number of big manufacturers get together and form a syndicate to run a permanent exhibition that shall travel from town to town all the year round. A manager and staff are appointed, and only one manufacturer of each particular trade is allowed to be a member of the syndicate. In this way each exhibitor has an absolute monopoly, and excellent work in the way of publicity is done. There are several such syndicates, each having from fourteen to eighteen members. It is found in practice that with fewer than twelve or fourteen the exhibition is more expensive to run than it need be, its overhead charges being unduly heavy per exhibitor, while with more than eighteen it is difficult to be sure of getting halls in the various towns visited that are large enough to accommodate all the exhibitors.

The method of working is as follows. Each exhibitor pays a regular subscription—about eight pounds per town visited. For this he has a certain regulation space allotted to him, and the services of the staff in managing the exhibition, erecting his stand, etc. Any special requirements, such as the laying on of water, etc., he pays himself. He also pays the wages of the attendants at his own stand. The subscription, however, includes printing, programmes, advertising, the services of a band, and other attractions. Where the syndicate is run well, there is usually a profit after each exhibition, which is divided among the syndicate members; and as good sales are made at the individual stands, an exhibitor may almost recoup himself for the outlay. As the plan followed gets the goods right into the hands of the public in the very best circumstances, it may be said that the syndicate exhibition is not only one of the cheapest, but also one of the very best forms, of advertising known. This applies, however, only to household commodities, as the type of exhibition is distinctly and exclusively one for the housewife. Cookery and laundry lectures are given, and visitors instructed in new ways, and the best ways, of using the goods of the various firms exhibiting at the stands.

Local Exhibitions. Many of these are held, and it is safe to say that quite 50 per cent. are of no use at all to the advertiser. If the entertainment element predominates, the manufacturer will do well to keep out, but on the other hand there are many good local exhibitions where excellent publicity can be had for proprietary household commodities at a reasonable outlay. In such cases, and indeed in most cases of exhibition publicity, it is well to

support the show by using the local newspapers. The spaces taken need not be large, but they should be in good positions, and the feature of the announcement must always be that the article may be seen or tasted at the exhibition now being held in a certain hall. The advertisement should appear in the papers on the opening day, and once or twice afterwards.

Foreign Exhibitions. Foreign exhibition propositions must be handled with great care. Of course, there are some of these which are invaluable to manufacturing firms desiring to secure a large share of the export business, but on the other hand many foreign exhibitions are not worth going into. The advertiser must be guided by personal considerations. If he wishes to increase his business in France, an exhibition in America is of no use; and it is practically a waste of time and money to go into a big Continental or American exposition unless the effort is to be supported and followed up by other methods of publicity and salesmanship. Attendants at such exhibitions should always speak the language of the country perfectly, and it is essential that they should know the trade customs of the country.

It will usually be found more economical when exhibiting abroad to get a light stand fitted up locally, rather than to send a heavy stand from home. Freights, etc., are extremely high, and the risks of getting the stand damaged are great.

Important Points to Remember. An important point to remember in connection with all exhibition advertising is that the first offer of space must not be accepted, however plausibly it may be backed up by statements that sites are letting fast, and that in a day or so no space will be available. It is practically always safe to wait a little, and usually a second or third offer will be accompanied by a note that for this occasion only a cheaper rental will be taken. On the other hand, an exhibitor should not hold back too long if he really wishes to go in, or he may find that the space he desires is let over his head.

Another very important point to be borne in mind in connection with all exhibitions is that stands and goods must be despatched at the right time. On no account must they be late in arriving at the hall; and if there are any exceptional circumstances, as in war time, when delays may be anticipated on the railways, then an extra day or so should be allowed. But we should not go to the other extreme, and send off our goods too early, as they may not be accepted at the hall, which will possibly be in other hands at the time, and a more or less heavy demurrage will be the result.

Permanent Exhibitions. There are one or two permanent exhibitions from which good publicity can be obtained. One of these is the exhibition of the Incorporated Institute of Hygiene, which has on its governing body more than fifty of the leading scientists of the country. This institute grants a certificate of merit for first-class commodities, and space can be rented quite reasonably in its museum by those firms who succeed in passing its test. The exhibits represent not only foods and drinks, but all kinds of hygienic appliances—baths, hot water apparatus, etc. The advantage of getting a show in this exhibition is that, while not a large number of the general public go to see the exhibits, visits are organised of bodies of influential persons, such as doctors, schoolmasters, nurses, and so on, people whose opinion counts, and who have much to do in directing the public. The institute also makes reports upon commodities, and these reports are well worth quoting in advertising literature, coming as they do from such an authoritative source.

Shop Demonstrations. Another form of publicity allied to exhibitions is that of giving demonstrations in shops and stores. This has proved extremely successful with household articles, and is in great favour with large manufacturing firms. Part of the counter may be used, or a small stand, or even a table may be set in the body of the shop. As good a display as possible of the demonstrating firm's goods is made in the space available, and a female attendant gives the demonstration, either at stated periods, say, every half-hour, or more or less continuously throughout the day. The demonstration may last a week, a fortnight, or even three weeks, and the shopkeeper supports it with a full window display, a distribution of invitations to his customers and to the better class of inhabitants round about, while bills on the shop window announce to the general public that the demonstration is being held inside, and that they are invited to walk in. If the shop is a very large one, the most prominent position available should be selected, and a space fairly near the entrance is good, because all who come into the shop then have to pass the place. In a large store, the demonstration will take place near the entrance to the particular department in which the article in question is sold.

Cost of Shop Demonstrations. Nothing definite can be said as to the cost of shop demonstrations. They vary according to the establishments in which they are being given. The large stores usually charge pretty stiffly for the use of the space, and in addition there is the cost of the material used, the advertising matter distributed, and the demonstrator's wages. If the demonstration is of a food cooked in various ways, then in addition there will be the cost of an attendant for washing-up purposes.

In smaller establishments, however, the space is usually given for nothing, and the shopkeeper is ready to lend every assistance to make the demonstration a success, for he realises, if he is an enterprising man, that the effort will result in increased business, to the mutual advantage of himself and the manufacturer. In such a case the general plan is to take from the shopkeeper's stock whatever materials may be required for the demonstration, paying him for them, and also for the manufacturer to pay for all advertising matter required—window bills, invitation cards, etc.

Often the shopkeeper can be induced, in return for the demonstration, to give a substantial order, the incentive held out by the manufacturer being that a greatly increased demand on the part of the public will warrant, and, indeed, necessitate, a more extensive stocking of the lines demonstrated. Here, again, the effort is largely lost if it is not followed up by other efforts from time to time. A booklet with a circular letter could be sent to each customer after a month or six weeks; this might be followed by another letter with a sample, and so on, everything, of course, being done in conjunction with the trader in whose shop the demonstration was given.

Window Displays. For all branded proprietary articles, whether foods, drinks, medicines, gas-burners, lawn-mowers, etc., window displays are very effective forms of publicity. They have this advantage: that the spectator who sees and is favourably impressed has an opportunity then and there of going in to buy the article. This is an opportunity he does not get

when reading an advertisement in a newspaper or magazine; and though he may be impressed at the time of reading, and determine to buy the article, yet enthusiasm and ardour are apt to cool off.

The method of obtaining a window display is to offer the shopkeeper some inducement in the way of a special discount or bonus on the goods he buys, or to give him free of charge a certain proportion of the goods required for the display. If a whole window can be obtained, so much the better. It takes a good deal of stuff, of course, to fill a whole window, but a large proportion of the things shown may be dummy packages provided by the manufacturer. When the display is in the window of a well-known shop, it always pays to take space in the local newspaper so as to draw the attention of the public to what is going on, and the cost may be shared by manufacturer and shopkeeper if necessary. The advertising department of the firm whose goods are being shown will have to prepare some attractive window bills, folders for distribution, etc. If a simultaneous series of window displays can be arranged throughout the country, or the district, or in the same town, so much the better. The cumulative effect brought about by the public seeing the goods everywhere will be very great and leave a lasting impression.

Bazaars and Sales of Work. Somewhat analogous to the forms of publicity already referred to above is the supplying of sample packages, free of charge or at a reduced rate, for sale at bazaars and sales of work. Most manufacturers of household commodities do a good deal of this, and it is certainly an excellent way of advertising and of putting one's goods right into the hands of the people. The articles need not be given; they can be charged for at such a rate as will practically cover the actual cost of the goods, though carriage and packing will be an out-of-pocket expense. The prices at which the articles are to be sold should be specified, and they should enable a profit of 100 per cent. on the cost to be realised. Great care must be taken that only sample packages are given for this purpose, or the manufacturer will find that he has set the local retailers against him. In addition to the advantage of having the goods actually taken into the homes of those who buy them, there is the publicity which comes from the display of them on the stall at the bazaar or sale, and very often an announcement is printed in the handbook giving the names of the firms who have assisted. Worked in the way indicated, this is a cheap and very efficient form of publicity.

Sampling Schemes. Another form of advertising which manufacturers have found successful in its results, especially with a new article, is that of distributing samples on a large scale. It is a very expensive form of publicity, but, as the final and permanent results so often prove really good, it is cheap in the long run. It is a method of advertising, however, that wants most exhaustive thinking and working out beforehand, and the cost wants very carefully estimating.

There are various ways of distributing the samples, each having some advantage over other schemes, and before any step is taken the particular scheme to be followed must be definitely decided. First of all, is the distribution to be general or local? The decision almost invariably arrived at is that it shall be confined to a certain locality, for anything like a general distribution of samples throughout the country is too expensive to be attempted at one time, especially as the mere distribution of samples is only a part of the campaign. This must be supported well by other forms of publicity, such as newspaper advertising, announcements on the hoardings, and the distribution of literature.

The next step is to decide how the samples shall be actually placed in the hands of the public. The cheapest way is to get the shopkeepers to do this; and if they can be enthused and made to see that every sample distributed is a silent salesman bringing them future customers, and if, realising this, they will themselves support the effort with recommendation, then the method is excellent. But many shopkeepers—especially the smaller ones, living self-centred lives—are so unappreciative of these efforts on the part of the manufacturer that they are not often ready to give their enthusiastic support.

Another method is to get a list of names and addresses, as up to date as possible, with the ineffectives weeded out by someone on the spot who knows, and then to post the samples addressed to each lady or gentleman, as the case may be, by name. Anything like a general inscription, "To the Occupier" or "To the Lady of the House," is to be strongly deprecated. Such methods belong to the past and are thoroughly worn out. Envelopes thus addressed bear on the face of them the obvious stamp of a wide advertising scheme, whereas the actual name of the person it is desired to reach gives an air of individuality to each package that is worth a great deal in arousing interest. Even if a large proportion are returned because the person named has gone away, it is worth while, in order to reach in so effective a way the remainder. For the same reason as we avoid general addresses, we should never have advertising packages franked in thousands at the post-office. Let every envelope bear an ordinary penny stamp—not a halfpenny one. Posting the samples is very good, but it is very expensive indeed if done on anything like a large scale. The prime advantage is that the sample is certain to get into the hands of the person for whom it is intended, as servants will not open a letter properly addressed to their employer and received through the post.

House to House Distribution. The most usual method of distributing samples on a large scale is by a house to house visitation. The first thing, after deciding the district or town to be visited, is to make a selection of streets to be worked. This should be done by someone who knows the district well, and can indicate the most suitable thoroughfares. In selecting these the poorer working quarters should be avoided, unless the sample to be given away is of some household necessity the selling point of which is cheapness. At the other extreme, it is seldom profitable to distribute samples at the doors of large houses where more than one servant is kept, for in such cases the packet is not likely to reach the lady of the house at all; it will certainly not get farther than the servants' hall. For this type of large house the postal system is best.

Having decided upon the streets, these should be marked in some way on a large-size, fold-up map. One way of doing this is to shade with a blue pencil the districts to be worked. The order in which the streets are tackled is best left to the person who has charge of the distribution. For this work it is not always easy to get a suitable man. The kind of person required is one with a good deal of tact, and considerable experience in managing people. He will have to keep his distributors in good humour, will have to see that they work energetically, will have to see that no packages go

astray, will have to check off the streets as they are worked, and may have to placate angry and unenterprising householders who object to receive something for nothing.

Since the advent of notices on gates and doorways, "No circulars, no hawkers," etc., the distribution of samples requires more tact than ever; and unless the person in charge is one with a good knowledge of human nature, the effort is liable to do more harm than good.

The Barrow and Distributors. The usual plan is to have one or more gangs, each of four men, with a youth to push the barrow in which the samples are carried. Where several gangs are at work in a district, the barrows are replenished either at a central depot or by means of a horse and cart, the latter containing a full day's supply for all the gangs at work. The carts and barrows should be attractively decorated, with the name and business of the firm conspicuously displayed.

The men who are actually doing the distribution under the overseer must be carefully chosen. In normal times there is no lack of men who will apply for such work when it is advertised, but a large proportion will be found to be ne'er-do-wells. Good references from more than one previous employer should always be insisted upon. The reputation of a firm is almost certain to suffer if its goods are given out from house to house by men of doubtful appearance or character, especially if they should be the worse for drink. As far as possible. abstainers should be selected for this work.

Uniforms of some kind should be provided for them, if only a cap with a coloured riband round it bearing the name of the firm. Also, it will be necessary to provide for each man a sou'-wester hat and waterproof cape and overalls. The wages paid will be about 25s. per week, the day being from nine to six, and from nine to twelve on Saturday. It is unwise to begin a distribution before nine in the morning, as householders do not want to be disturbed during the breakfast-time.

Method of Distribution. The usual way of working is to let two men go down one side of a street, and two men down the other. Both pairs will thus get to the end of the street at about the same time, and the barrow can move down slowly, keeping pace with the distributors. The men carry either satchels, slung round their shoulders, or handbags, and in these they take a certain quantity of samples, varying according to the size and weight of the packages. When his bag is empty a man goes to the barrow and loads up the satchel again, the barrow man keeping a note of the number served out to each individual on each occasion. In all cases the quantity should be a certain specified number of packages—say, twenty-five—and if all the men are honest there will be no difficulty in keeping a proper check. The men on each side take alternate houses, and thus keep together as they go down the thoroughfare.

If several groups are working in a district, the overseer will have to be a very energetic man if he is to keep his distributors up to the mark. His plan will be, of course, to dodge here, there, and everywhere, so that the distributors never know when and from what direction he will appear.

The men must be engaged on a weekly basis, unless they are local men, and if they are taken from town to town their fares must be paid. An hour should be allowed for dinner each day. Every evening the overseer must send to his firm a sheet showing any expenses incurred, a list of streets done, with remarks about any particular houses that need comment, and a general report as to the weather, the men, the reception of the samples, etc.

The Samples and Literature. In making up the packages, they should be neat and attractive. With the samples will be enclosed some literature, but not too much. One really attractive and interesting-looking booklet, telling the whole story about the firm and its products, is better than half a dozen of varied sizes, qualities, and subjects. There is always the danger—in many cases amounting to a certainty—that a great wad of printed matter will be thrown away bodily without being looked at. In any case, the sample should have enclosed with it a form letter, brief and to the point, telling the recipient what the article is, and asking him or her to try it.

Form Letters. These form letters must be very carefully prepared. They should be typewritten in appearance, and not set up from printers' type, however good it may be. Duplicating appliances like the Gammeter Multigraph, already described in the Business section, have been perfected, and are able to produce circular letters almost as fast as a printing-press. The great advantage of such an apparatus is that the letter is actually the same as a typewritten document, for the type does not print direct upon the paper, but through an inked ribbon in the same way as the typewriter; and as the type of any of the standard typewriters may be used with the instrument, names and addresses and dates may, whenever desired, be filled in to match the letters. Form letters should always be short, never running to more than one page of quarto notepaper.

Working the Trade. Of course, if a sampling scheme such as that described above is to be carried out in a district, the trade there must be thoroughly worked beforehand by the regular salesman, or a special man put on for the purpose. The shops must be stocked up, so that when the demand is created, and people begin to ask for the goods, they can obtain them without delay. If they fail the first time, they may not ask again. If a large number of shops are thus stocked up, it is sometimes a good idea to send out with the samples a list of the shops in the neighbourhood where the goods may be obtained. By letting the shopkeepers know this beforehand, it is often possible to get those to stock up who would otherwise not help in the scheme. They are anxious not to lose the publicity that results from their names being on the printed list. This important detail of working the trade in connection with a sampling scheme is a proof of how essential it is that the sales and advertising departments should work together.

Another Method of Distribution. Another method of distribution organised by agencies that lay themselves out specially for this work is for lady distributors to go from house to house selling, not giving, the goods. Simultaneously they work the trade, and all the goods sold to the householders are bought from the stock of the shopkeepers. This is done so that the local traders may not be upset by the scheme, but any plan of this kind needs great care in working out, as the shopkeepers are proverbially suspicious of all schemes in which the manufacturers go direct to the consumer. In any case, it would be unwise for any manufacturer to attempt such a scheme direct with a staff of his own. It is best left to the agencies who specialise in it, who know the ropes, and who have a thoroughly trained and experienced staff of competent women workers.

Organised Visits to Factories. Somewhat analogous to exhibitions and demonstrations are the organised visits to their factories which many manufacturers now encourage. It is always a sure way of interesting the shopkeeper in the goods he sells if he can see them made; and in the case of food products, if the conditions of manufacture are all that can be desired from the hygienic point of view, then too many people cannot pass through the factory. For trade visits, the best plan is to organise an outing for the trade association of some particular town, getting the permission of the officials to allow other trades to join who do not happen to be members of the association, although they are good customers of the manufacturer. Such customers, when outside the trade organisation, must not be ignored.

In some cases, where an association has asked to be allowed to visit the works, the members would pay their own fares to the nearest station, while if they came by invitation of the manufacturer, he making the first approaches, fares would probably be paid by him. The exact plan to be followed must be decided according to local conditions. If the works are in or near a town which has objects and buildings of great historic interest, then a drive round the town, with a call at the more important show-places, could begin the day's festivities. Luncheon may be served at an hotel or in the works, according to facilities, and at this there may be speeches and toasts or not, according to taste. But in any case the chairman—who will be the managing director, sales manager, advertising manager, or some other prominent official—will give a welcome to the visitors and outline the afternoon's proceedings.

The trip through the factory will be made in parties of a dozen or so, each party being conducted by a guide; and the visitors must be well schooled beforehand not to speak to the employees, not to wander about away from their guide, and not to interfere with the work that is going on in the various departments. After the journey through the works, tea should be served, and the proceedings may be wound up with an impromptu concert, unless, as is done by some firms, a dinner is to be given in the evening. This would, of course, have to be at an hotel, unless there were special facilities for catering at the works. Whatever amenities there may be, the last impression the visitors receive, the one that they will take away with them, should be of the factory and firm, and the products it turns out. There should always be a sample-room, well stocked, into which the trade visitors can go and see the latest lines, and here the sales manager and his assistants should be ready with their order-books, although solicitation for orders on such an occasion would be out of place. Solicitation, however, will not be necessary, for the experience of firms who go in for this form of advertising is that if the visitors have enjoyed themselves, and been impressed with what they have seen, they will show their appreciation by giving orders.

The General Public. Visits of this kind, however, should not be confined to the trade. The general public should be invited, and the more the merrier. Some firms issue a standing invitation to consumers of their goods, vouchers being enclosed with their packages. In these cases, if the factory is easily accessible in a large town, and the number of people who will respond may be anticipated to become large, it is best to set apart a certain day or certain days per week, so that the visits may be concentrated. In this way, time will not be wasted.

But not only should members of the general public be thus invited promiscuously. Visits of representative bodies should be organised, particularly in the case of firms producing foodstuffs. There is an enormous number of associations available—learned societies, medical and municipal bodies, religious and temperance organisations, suffrage societies, etc.; and women visitors are even more valuable than men, for if they go away enthusiastic and impressed they talk more than the men. Each lady becomes a walking and talking advertisement.

Of course, in taking visitors round, a certain recognised route can be followed. It is not necessary to let everyone see everything; and in the case of one large firm that invited a body of visiting burgomasters to see their works, so that these foreign business men should not see too much a doorway was made specially in a particular wall, in order that it should not be necessary to take them through certain departments of the factory.

Souvenirs for Visitors. Of course, it will be necessary to have some suitable souvenir prepared to hand the visitors as they leave, and this should be of such a character that it will be kept, and act as a constant reminder to the visitors, long after the visit is over. The particular form of the souvenir must be decided by each firm for itself, but in any case it should be thoroughly well illustrated; and if the pictures can be in colour, excellent effects can be obtained in two colours.

The reading matter should not be too long, but it should be descriptive of the factory and its products, and should tell the whole story in a bright and connected manner. The booklet could be packed in an envelope with some other advertising literature, but the main booklet should be distinctly a souvenir, and should be called by that name.

Following up a Visit. All visitors should be asked to sign their names and addresses in a visitors' book, and this then becomes an excellent register of people interested in the firm and its productions. Should any new line be brought out, here is a carefully selected list ready to hand for advertising or sampling purposes. But, apart from new lines, the firm should keep in touch with these people, and any new booklet could be posted to them, together with a form letter reminding them of their pleasant visit. So far as trade visits are concerned, the statistical department will keep a record of the visitors, and from time to time their record of business will be looked up and compared with the corresponding period prior to the visit. It will then be seen to what extent business has been increased and helped by this form of publicity.

School Advertising. A form of advertising regarded as very valuable by many firms is that in which picture diagrams, booklets, and museums of products are sent to schools. With regard to the latter, the museum is, of course, costly to prepare. There is the case, consisting of a mahogany and glass cabinet for standing, or hanging on a wall. And then there are the various products to be placed inside. But if the teachers are going to give object-lessons on the products to succeeding generations of boys and girls, who will be the mothers and fathers of the future, then for household commodities this is certainly a method of publicity that should have far-reaching effects. The objects in the museum should, as far as possible, show the successive stages through which the product goes before it becomes the finished article known to commerce, There should, if possible, be the raw material.

and any stages which cannot be shown in the product itself can be shown by pictures.

The museum cases should, of course, have the name of the firm conspicuously displayed in gilt, and it should be understood that it is to stand in the school hall. Some of the contents will probably need periodical renewing, and some arrangement should be made with the schoolmaster to let the firm know when this is necessary.

Large coloured showcards illustrating methods of manufacture are also welcome in elementary schools, and if they are displayed on the walls of the hall they form an excellent advertisement. Another form of advertising in schools is to supply dummies and samples for use in model shops. This is the way in which arithmetic is now taught in many schools; and it is obvious that the name of a firm whose jams, cocoa, mustard, or soap is being constantly handled, talked, and written about will remain in the minds of the children, and probably recur later on, when, having grown up, they engage seriously in housekeeping on their own account.

At Christmas-time there is always a demand for toy-books, coloured picture-postcards, novelties, and similar advertising matter for distribution among children, and hundreds of thousands of pounds are spent every year by the large manufacturers in preparing material for use in this way. Such advertising is not merely laying up treasure for the future, but it has its present advantages, for much of it is talked about in the home, and so the present buyers are influenced and have the names of manufacturers brought frequently before them by their children.

The media of advertising are, of course, legion, and no firm, however large its annual appropriation, can afford to use all or anything like all the fields that are open to it. A selection must be made; and the particular nature of the selection depends upon the character of the business to be advertised and the class of people it is desired to reach.

New realms for the advertiser are constantly opening out; and as an example of how opportunity may be seized and current happenings be harnessed for the purposes of publicity, we may refer to the shades used to darken the lights in shops and omnibuses during the time that aircraft raids were expected over London and other large cities. Advertisers saw their chance, and quickly seized it, and thousands of shades came into use bearing upon them the names of somebody's soap or such-and-such a food. Sometimes the advertisement was printed on the paper, and at other times the letters were cut out and filled in with a different coloured paper from that used for the shade itself, thereby making a very effective notice when the lamps were alight. The space available will allow of nothing like an extended description of all the media open to the advertiser, but brief references may be made to the more important not yet touched on.

Railway Advertising. One very important branch is railway advertising, and this is so varied that in itself it would provide sufficient for a lengthy volume. The oldest and most obvious form of railway advertising is that at railway stations, and very large revenues are made annually by the railway companies from this source. It is certainly effective, despite the fact that in the rush and hurry of catching trains people might be expected to have little time or inclination to attend to such matters. On the other hand, it must be remembered that there is a good deal of waiting about at stations, including the great terminuses, and people are glad of something to look at. On such occasions there is little inclination to read books or even papers; and there is no doubt that constantly seeing an announcement about some article of wear, some magazine, some household commodity, or a tobacco or drink, does leave an impression on the mind. The effectiveness of advertising in this way at railway stations has been proved again and again, and some articles which are now household words have had their reputations and extensive sales built up almost exclusively by publicity at railway stations.

Enamel Plates. The general method in vogue is to do the advertising by means of enamelled iron plates. These can be exceedingly attractive; very bright colours are attainable, and they have the great merit not only of resisting the weather but of being easily cleaned, and a good rainstorm improves them, for it acts as a bath. This station advertising is in the hands of responsible agents, who charge so much per square foot per annum by way of rental, and for good-sized orders they will usually prepare the plates free of charge. The rental, too, is generally on a sliding scale, according to the size of the order. The advertiser is allowed to select his stations, and, as far as they are available, his positions, being taken round for this purpose by the agent.

The first thing to decide upon is the amount to be spent at the stations, then to arrive at the number of square feet this will purchase, and then to fix the exact size the plates are to be. The temptation is, of course, to reduce the size of the plates and increase the number of stations, so as to get as wide a publicity as possible. But very great caution must be exercised in the matter; for in the multitude of announcements that now crowd our stations, unless one puts up a plate of a fair size, it will be buried or overshadowed.

Restricting Wording and Colouring. Another great temptation in railway-station advertising is to want to say too much. The name of the product, the phrase of two or three words, is all that the public can safely be expected to take in in the peculiar circumstances of the case, and by overcrowding the announcement practically the whole of the advertising may be lost. In some cases it may be wise to give a reproduction of the article or package advertised, but this is not often necessary, and is not generally done, as a glance at any great terminus will show. When, however, there is something peculiar about the package, as in the case of the bottle in which a certain tooth preparation has long been sold, it is excellent publicity to show this.

The particular colours to be used need a good deal of thought, and here, again, the temptation is often to overdo the business, to use a variety of colours where two or three will give a more striking and effective display. It is wise to look and see what are the prevailing colours being used, and as far as possible to get something different, but the striving after variety and individuality must not be strained to the extent of turning out something that, while different, is also ineffective. The best colour for a background—that is, for the body of a plate—is red or yellow, the former not crimson but a bright scarlet or vermilion, and the latter a rich canary or chrome. On the yellow, black letters show up best, and on the scarlet black or white look well. Black should never be used for a background, as it is too sombre, and this applies in a less degree to other very dark shades, such as a deep bronze-blue, and the like.

Inspecting Railway Announcements. When the plates have been prepared and fixed in the positions selected, a visit should be paid to all the stations, to see that they are actually up in the places arranged; and while the agents will undertake to see that they are kept in a clean and fit condition, it is not wise to leave the matter entirely to them. Periodical visits should be paid to the various stations, just for the satisfaction of knowing that all is right. Any firm advertising in this way should make good use of its statistical department, watching the amount of business done at the various places where the plates are showing; and it will be seen after a few months whether the publicity is bringing results.

Announcements in Booking-halls. A new method of advertising at the great terminuses and the larger stations has quite recently come into operation. This is by means of advertisements prepared in inlaid wood and arranged in panels round about the pigeon-holes where tickets are served out. They are rather dull in appearance, but as most booking-halls are dismal places, and there are few counter-attractions, they may do some good. But it is a great question whether publicity of this kind in such a place is of such value as to warrant the expenditure involved. Booking-halls are not, like platforms and the great central halls of stations, places where people hang about, and are therefore glad of something to read. Travellers usually get their tickets with as much expedition as possible; and if they have to wait in a queue to get to the window, they are too intent upon the business in hand to concern themselves very much with advertisements that appear an inch or two from their faces.

Advertisements in Railway Carriages. Some of the railway companies take advertisements for the insides of their carriages. In some cases these appear in panels just under the luggage-racks, so as to face the traveller, and in others they appear as narrow panels on each side of the carriage door. This latter position is, of course, not so good as the first-mentioned. Under the rack and above the heads of passengers sitting on the seat, an advertisement can be seen by all on the opposite seat; and as the companies have for years past educated the public up to looking at these panels, by placing excellent views of beauty-spots in them, there is no doubt that good publicity can be obtained by taking a range of such spaces. The rentals are not dear, and the best trains are, of course, the suburbans and locals, as they carry a constant succession of different passengers.

On the London underground railway and tubes, the announcements appear in various places—above the windows on each side of the carriage, on the woodwork between the windows, on some of the seats, at the ends of the carriage, etc. The number of passengers carried in the course of a year is enormous, and the publicity obtained is very valuable. Almost the same remarks that were made in connection with the announcements on enamel plates at stations apply to the announcements inside railway carriages. They must be brief and the lettering as large as possible. The spaces are very limited in size, and if much matter is inserted the type will have to be so small that from 25 to 50 per cent. of the passengers will never be able to read it at all. Some of the companies put certain restrictions on the design and colouring and in a general way the design and colouring do not need to be so striking as in the larger outdoor advertisements.

Railway Ticket Advertising. The latest development in railway advertising is in connection with the underground railways of London, certain of which are taking advertisements for the backs of their tickets. A few years ago such a move would have been thought inconceivable, but there is no doubt that the innovation has come to stay, and that it will before long be extended to other lines too. Of course, there is probably less value in an announcement on a railway ticket than on a ticket for an omnibus or tram, for whereas the passenger may, if he wish, retain the latter, the railway ticket has to be surrendered at the end of the journey. Not only so, but when people travel by train they are usually equipped with reading matter, and are far less in the habit of looking at their tickets than when on the road vehicles.

The companies, however, do their best to make the advertising useful, drawing attention to the tickets by means of announcements posted up at the entrances to the stations, and by other means.

Tramcars. From railways it is not a far thought to tramcars, and here a good deal of publicity of an excellent kind is available. The tramcar may almost be said to combine a good deal of the advantage of the poster on the hoarding with the circulation of the newspaper, for while the outside announcements on the car are, in effect, posters, the tramcar, moving backward and forwards through miles of crowded streets, reaches a far larger circle of the public than any mere stationary poster on a wall or hoarding. It is brought before the notice of people in the streets, and it is equally visible to the thousands of people who live in the houses on either side of the thoroughfares through which it passes daily.

The advertisements on the outsides of tramcars are prepared on enamel plates just like those at railway stations, and they run round the top of the car, but the whole area need not be taken, as the space is divided generally into sides and ends. In many towns, too, narrow enamelled plates are fixed to the drop of each step on the staircase back and front.

Window Transparencies in Cars. The advertising inside the cars is in the form of transparencies on the upper lights of the windows along each side, and are intended for the perusal of passengers, but some advertisers have at least one transparency turned so as to read from the outside. This, of course, is only legible after dark, when the car is lighted inside. It is very questionable if there is much value in such a plan, and it may be taken for granted that in a general way all transparencies should read from the inside of the car.

Contracts for Tram Advertising. The system of advertising in tramcars is to contract for so many cars in so many towns for so many years. An annual charge is made per car, and for good contracts the corporations of the various towns or their agents will prepare, free of charge, all plates and transparencies needed, submitting proofs for approval. As to the relative values of whole cars or parts of cars, each advertiser must decide for himself. There is much to be said both ways, and naturally a good deal depends upon the commodity and the circumstances of the campaign. When six or more whole cars are taken, an extra car can generally be obtained free, and where a tramcar scheme is in view the agents are generally willing to prepare and give a trial car for a time free of charge. Such free advertising, where a

tramcar scheme is going to be adopted, should be taken full advantage of.

After the advertisements are all in position, they must be carefully examined from time to time, to see that the transparencies are untorn and the plates clean and unchipped. This inspection takes a good deal of time, as a rule, for it is difficult to catch all the cars in a limited space of time unless the sheds are visited in the very early hours of the morning. An arrangement is usually made that not more than one car bearing a firm's advertisements shall be laid up for repairs or repainting at any one time. From time to time the announcements may be changed, but this must not be done too often, on account of the cost of preparing new plates.

Omnibuses. Similar advertising is carried out in connection with omnibuses, both motor and horse; and as these vehicles are generally owned by private companies and not by municipalities, they are less particular about restricting the amount of advertising to be done. In most cases every available spot is used, both inside and out, as a glance at any ordinary motor-'bus will show. While enamelled plates are almost invariably used for the staircases and smaller positions, posters printed on paper of the right size are very often used for the sides of the 'bus at the top. In cities and large towns, theatres and big drapery houses are very partial to these outside positions on the sides of omnibuses.

Tram and Omnibus Tickets. If mere circulation were everything, then advertising on the backs of 'bus and tram tickets would be the first and foremost of all methods of publicity. Unfortunately for the simplicity of the business, circulation in such a case is far from being everything, for while a firm's announcements may appear upon a series of, say, ten million 'bus or tram tickets, vast numbers of these, though placed in the hands of passengers, are never read at all. After riding in a vehicle once or twice and watching the people, and seeing how persistently they all seem to ignore the reading matter on their tickets, it might seem that such a method of publicity was worth very little, but, as in the case of all other media, the true test is the sales effected; and those who use tram and 'bus tickets in a large way declare that the results are good. The statement must, however, be qualified by the remark that only certain articles of very general use should be advertised in this way, and the publicity must be supported by other methods. The tram or 'bus ticket is at its best, from the advertising point of view, when it is being used merely as a reminder of the name of some article of household use, some well-known tobacco, or a popular drink.

Stamp Books. Though in another sphere, the publicity obtained from announcements in books of postage-stamps is on somewhat similar lines to that of tram and omnibus tickets. This is a comparatively new medium, but it is popular with advertisers, and may be said to have justified itself by results. Here advertisers are limited to a very small space, as in the case of the ticket, and the printing has to be in the one colour, green, which is used for the interleaves. Here, again, mere circulation figures are of little value as a criterion of value, for there is no doubt that great numbers of the people who buy the books never look at the advertisements. In regard to these little books, it is probably true that the back cover is of more value than any other part.

Showcards. When we come to showcards we are dealing with a very important branch of advertising, one on which our great manufacturing firms spend hundreds of thousands of pounds every year. A great army of artists, lithographers, printers, and so on is engaged in doing nothing else but turning out showcards, and much real artistic gift and mechanical ingenuity are now brought to bear to make these worthy representatives of the firms that issue them and of the goods they represent.

So much care is given to this matter nowadays that it may almost be said with truth that the majority of showcards are comparatively good, but every firm is striving after something that is more than good, and every now and again it gets it. Sometimes this comes by a happy inspiration. The advertising manager or a colleague hits upon a novel idea, and a first-class commercial artist catches the inspiration and carries out the idea to perfection. Sometimes an artist belonging to a printing firm strikes an idea and carries it out, and when this is shown to some likely firm the advertising manager realises at first glances that this is the very thing he has been looking for.

Designs for Showcards. Different advertisers have different ideas for showcards; and while some will lean to pictures that, though beautiful and attractive, have no connection with the article or commodity advertised—as, for instance, a beautiful Swiss lake and mountain scene for a brand of whisky—others avoid fancy pictures, and get something more directly connected with their goods, as, for example, a mass of fruit or an orchard for a jam. There can be no doubt that, from the advertising point of view, the latter is the better scheme.

In every showcard the picture should tell the story independently of the wording, for the impression gained through the eye, though often unconscious, is pretty certain to last. The beholder will not reason out from a picture of magnificent fruit and a beautiful orchard to jam made of this very fruit, but she will quite unconsciously connect up the things, and the particular brand of preserve advertised by the design will always remain connected up in her mind with fine fruit and a delightful country scene. There is no need for a picture that tells the story to be ugly. If necessary, the figure of a beautiful girl can always be introduced, but in doing this care must be taken that the subsidiary part of the picture—subsidiary, that is, from the advertising point of view—is not so attractive as to hold all the attention of the spectator, and thereby to detract from the main object. Wherever possible, the article advertised should be shown in facsimile somewhere on the showcard.

Distributing Showcards. The old method of distributing showcards was very wasteful. They were sent out to every purchaser of the goods, quite independently of whether he wanted them or whether there was any likelihood of his being able to show them. No matter how artistic or costly they were, at least 50 per cent. were generally wasted. Up-to-date firms do not do this now. They give an opportunity for every customer to indicate, either on an order form or a special slip, or through the traveller, what showcards he can make use of; and it may be taken as a general axiom that if a shopkeeper asks for a card he will exhibit it.

It must not be supposed, when the cards are bought and paid for, that that is the end of the expense. They have to be sent out, and for

this purpose strawboard packing is needed if the cards are to arrive at their destinations in anything like presentable condition. Then there will be freight or postage unless they are sent in the cases with the goods they advertise. This raises the question of the size of showcards. They should not be so large as to be ungainly, and, unless the cases in which the goods are packed are very small, should be made of such a size as to go in these. On the other hand, they must not be too small, or they are apt to look mean and give a poor impression of the goods they describe. By placing them in the case with the goods, not only the separate freight will be saved, but also the packing, or, at any rate, a large proportion of it.

Rectangular Cards versus Cutouts. While rectangular cards are very good, and may be made extremely effective, cutouts are still more attractive, and an enormous amount of real ingenuity and inventive genius is being expended in producing cutouts that are new and clever. A number of points must, however, be borne in mind when ordering cutouts. In the first place, mere cleverness alone should not decide the matter; for while an ingenious contrivances may be excellent when the card is handled carefully in an office, it may be too complicated or intricate for adoption in a cutout that is to go out by thousands and be handled by shop assistants who will possibly exercise very little care in fitting it up for the window. For this reason, the less complication and fitting together of parts, such as slipping strips into slots, etc., that is required the better.

In the second place, care must be taken to see that any secondary parts, struts, tapes, etc., are firmly attached, and will not come apart with a little handling. There is nothing more annoying to the shopkeeper than to receive a cutout which requires adjusting, and as soon as he begins to get it ready for the window or counter he finds that it breaks or comes unstuck. He will probably at once pitch it away, and the shilling or so spent by the manufacturer is simply lost.

In the third place, when ordering a cutout, we should endeavour to select one that has no parts connected with the main body merely by a very narrow isthmus, as, for instance, a hand holding a box connected with the body by a very narrow wrist and arm. The least knock will break a cutout of this kind, and it is at once useless. The difficulty can always be got over in the design by a rearrangement of attitude or clothing, or in some such way.

A fourth point to remember, in ordering a cutout, is to have one that will pack easily for despatch. Most designs can be simplified, and it is well to remember this when considering a cutout. Finally, a fifth point that should not be overlooked is the substance of the card. There is sometimes a temptation to cheapen the cost of the cutout by reducing the substance of the card on which it is mounted, but this is penny wise and pound foolish, as not only will the card warp far more easily, but it will crack with a slight knock or blow. So much for the cutout as a practical advertising medium. Many an ingenious design is planned, and looks very well in an office, as already explained, but we must bear in mind the practical considerations set forth.

Dummy Packages. Connected with the subject of showcards is that of dummy packages. These prove very useful as advertising devices, particularly where perishable goods are concerned, which would deteriorate by exposure to light and sunshine in a shop window. The dummy packages may be just the ordinary labelled boxes or jars or tins in which the goods are packed, or they may be facsimiles of piles of these in the nature really of cutouts, or they may be giant facsimiles or imitations of the packages—as, for instance, a condensed milk tin as large as a dustbin. A good many advertisers, however, hold that though the giant facsimile is striking, and may attract attention, there is nothing better than to familiarise the public with the actual packages which they buy or are expected to buy. For this purpose the boxes or jars or tins themselves are regarded as preferable, or, as a second-best scheme, cardboard facsimiles, such as all the first-class lithographic printers now turn out.

Models and Figures in Windows. A growing practice by keen shop and store keepers is at certain seasons for them to do out their windows to represent some scene connected with their business—a fishing scene for a firm dealing in canned salmon, sardines, etc., or a jungle scene for those dealing in furs. For these, stuffed animals, properly dressed, lay figures, and model trees, boats, etc., are used. The plan is good as an attraction, but the danger is to leave it at that, whereas the plan should be to let it be not merely an attraction but also an advertisement of the goods. This is effected by connecting up the scene with the articles, by having these displayed prominently at the sides, in the front, or somewhere naturally in the scene itself.

Working Models. Working models are very good as attractions, and always draw a crowd, but here again there is a danger of letting the models be independent of direct advertising, and thinking that if a crowd is attracted to the window the whole business is done. A moving windmill, for example, would be very good in connection with a particular brand of flour or bread, but it should be surrounded by bags of the flour or loaves of the bread, and should have prominently printed on it somewhere the name of the flour or the manufacturer, as the case may be.

Billposting. Leaving the showcard and its allies, we now come to billposting, a form of advertising that has made great strides of late years. It is a somewhat expensive form of publicity, but a very effective one, a form that has for half a century or more proved its worth. The strides of recent years have been not so much in the direction of quantity as in the way of quality. Some of the greatest businesses of the day began their advertising a quarter or half a century ago on the hoardings of London and other large cities. The hoardings are nearly all in the hands of a few large firms in each town, which simplifies matters from the advertiser's point of view; but when planning a campaign and selecting the stations very great discretion must be used to choose those that shall be in neighbourhoods where the article advertised is likely to sell, or through which large numbers of the people who may buy it will pass. Obviously, every poster in a poor district advertising an expensive table-water would be sheer waste, while to advertise a cheap margarine in the best part of Belgravia would be equally foolish. The whole matter is one for the exercise of care and common sense.

If any proof were needed that poster advertising pays, the great recruiting campaign which raised an army of millions in a few months entirely by the voluntary principle would be proof enough, for this army has been gathered together more by poster

appeals than by any other means. Even the newspapers—which sometimes talk as though newspaper advertising were really the only form of publicity that counted—invariably use the hoardings when they wish to reach the public with some big, new proposition.

Localisation Value of the Poster. One of the great advantages of poster advertising is its adaptability to localisation. Better is it for such a purpose even than a local newspaper, for the latter always has a certain amount of circulation outside the actual district to be worked, which is therefore wasted advertising, whereas the poster can be confined absolutely to any district, however large or small it may be. Not only so, but while the newspaper will not be read by everyone in the town, the posters—if well placed—will be seen by practically all the inhabitants.

Designs for Posters. During the past twenty years there has been a revolution achieved in poster design. Formerly the crudest colouring and pictures were considered good enough for the walls, but now some of our best artists design the posters that advertise our leading household commodities, beverages, theatres, and so on. It must always be remembered that a poster design must be considered on its own account, quite independent of other forms of advertising. In other words, what will make an excellent showcard or cutout, or cover design for a folder, will not necessarily form a good poster.

Posters should always be pictorial, and the picture should invariably tell the story so that if the observer catches nothing but the name of the firm, or proprietary article or trade mark, on the bill he will nevertheless, from the picture which leaves a mental impression, carry away some fact or thought that shall be to the advantage of the article advertised. No hard and fast lines can, of course, be laid down, but a glance at any of the fine hoardings which are to be seen all over our great cities and towns will reveal the kind of poster that is most effective.

Humorous Posters. And here a word must be said about the value of humour on a poster. Here, more than anywhere, perhaps, in the whole range of advertising opportunity, is humour permissible and advantageous. As Mr. John Hassall, a master in the business, has well said: "The majority of the advertisements which are remembered will be found to be humorous. This shows how valuable they are in attracting the reader's attention. For that reason you will find that most of the advertisers spending the greatest amount annually use humour very largely in their appeals to the public." The humour must be fairly obvious. If it is subtle, it will be beyond the conception of the average passer-by. And it need scarcely be mentioned that it must not be in any sense vulgar.

Simplicity the Essence of Success. Simplicity is the essence of success in a poster. Anything complicated, either in the way of design or of idea, should be avoided. The first requires a long examination to unravel its meaning, and the latter needs an effort of brain that few people will take the trouble to make. The wording, too, must be very short, very plain, and very simple. The less said on a poster the better. "You cannot put much argument on a poster," says Mr. Hassall. "In fact, the sole purpose of the poster is to familiarise the public with the name of the article. The name must be arranged so as to be clearly seen in connection with the picture to which it belongs, and it should not be placed where it might seem to belong to some other poster. One very important thing about a poster is that it should really advertise the intended article, and not something else."

Except in the very rarest cases, the idea should come first, and the poster be designed to illustrate the idea, otherwise there will not be the concerted emphasis which is necessary to make a poster really successful. In this respect the artist has an opportunity which is not so well open to the photographer. A writer has said: "The drawn advertisement pictorially is always able to tell its story, not only much more decisively than the photographic illustration, but much more quickly. And in advertisements it is time that marks the efficiency of the announcement all the while. The copy that 'gets home first' is making an impression that will, for the time being at least, exclude others. Designers of posters and of other advertising illustrations are beginning to realise this. The successful poster is the one in which there is this concerted emphasis. It takes its point, holds it well in front, and presses it home. The other portion of the poster is merely a foil to it. In the poster this is imperative. The poster which neglects this factor—and there are many—is almost wholly wasted effort."

Sizes of Posters. The unit of measurement in posters is the double-crown bill, which is 20 in. by 30 in. It is the size of the ordinary newspaper bill seen outside the newsagent's shop every morning and evening. All other sizes in posters are multiples of this, and are spoken of in terms of sheets. Thus, one double-crown poster is spoken of as a single-sheet bill, a poster twice that size, 30 in. by 40 in., is a two-sheet bill, and so on. The double-crown bill is the unit, and this must be remembered. Of course, the big poster is not made up of the number of sheets which its name would imply. For example, an eight-sheet bill may be printed in two sheets, and would not, in any case, be in eight parts. The sheet refers to area, and not to number.

Cost of Billposting. Billposting can, of course, be experimented with or tried on any scale, large or small. "Covering the country," says Mr. Cyril Sheldon, "is one thing, but entering upon an ordinary billposting campaign is quite another matter. Suppose an advertiser was broad-minded enough to wish to discover for himself by means of a practical experiment whether the use of posters was suited to his business or not. This need not be such a heartbreaking matter. For an expenditure of about £350 a trial campaign could be made in an area embracing a population of about a million. This would allow for the posting of a sixteen-sheet double-crown (120 in. by 80 in.) bill in suitable quantities in each town in the area for a period of three months, together with the necessary bills, well printed and designed by a good artist. This would be an expensive experiment, in that the number of bills required would be so few, and those few would have to bear the whole cost of the original design, and the putting on to stone, whereas if the bills were part of a general order for printing, the cost would be reduced at least £50.

"It would not be at all difficult to select an area where the cost of posters is lower than the one allowed for, making a consequent decrease in the cost of the experiment, but it is not desired to put the case on the lowest possible basis, but rather on an average basis. There is a good deal of talk about 'circulation' at the present time; and if billposting were to be judged by that test, and judged with fairness, there would not be sufficient hoardings in existence to accommodate the inrush of posters

there would assuredly be, for it must be remembered that the £350 covers the cost of exhibition, not for one day, but for ninety-one days, and there is no 'circulation' to be had anywhere else within a gunshot of this for economy."

One other point must be mentioned in connection with billposting, and that is the importance of proper checking while the bills are up. Even billposting firms may make mistakes, and therefore the advertiser should always have a competent person go round from time to time to see that the posters are duly put up in the selected positions, and that they are all in a presentable condition. The life of a poster varies tremendously. In dry weather, on a fairly high and protected position, it will be considerable, but if the bill be posted where mischievous boys can get at it, to tear it or to scribble upon it, it will be mutilated almost as soon as it is up. This should be borne in mind in selecting sites. In wet weather, of course, posters have a bad time, although there are now waterproof pastes and water-resisting papers.

Electric and Illuminated Signs. Signs that are lighted up at night, or that change letter by letter by the lighting and extinguishing of electric lamps, are very popular forms of advertising, and in crowded thoroughfares with wide vistas are very effective. They may almost be regarded as night posters, and their advertising value is perhaps more than that of even the artistic picture poster, for, being fewer in number, they attract more attention. They are, however, expensive, and should only be used as supplementary by a big advertiser, or for a definitely local purpose.

Cinema Advertising. The growth of the picture palace during recent years has led to its utilisation for advertising purposes by many of the large manufacturers of household commodities. The method in favour up till quite recently was to have a film illustrating the manufacture of some article, such as cocoa, jam, etc., but the popular taste finds such exhibitions rather too heavy as part of a general entertainment, and more lively or subtle methods are now in vogue. One plan is for the article that is to be advertised to be introduced into the scene of some ordinary humorous film. A box of a well-known breakfast food or a brand of some well-known brand of jam is standing on a table, while the characters carry out their acting. More elaborate is the humorous film given up entirely to the article. A box of chocolates, for instance, appears on a table, the lid opens, the sweets jump out, dance about, form faces and other designs, and then form into the name of the manufacturer. They then spring back into the box, it closes, and dances off the screen. This ends the film, but people who have seen it describe it to their friends, and in doing so can hardly fail to mention the brand of chocolate.

These trick films, before the war came very largely from the Continent, particularly Germany, and the objection to many of them has been that, where figures were introduced, these had a very foreign appearance. It is safe to say that this style of advertising has come to stay, and there is no doubt that the films will be more than ever prepared in this country.

The principal danger always to be guarded against is that of vulgarity. Many of the films are humorous, and it is very easy for humour to become too broad, an expression of the face, a gesture, making all the difference between that which is legitimate and that which has a cheapening effect upon the article advertised.

Making the Best of the Cinematograph. This, however, while wonderful and likely to be talked about, is not the best kind of advertising film. As an illustration of how well the moving picture may be made to tell the whole story about a household commodity, the following example will show. It was one of a series of films shown at a demonstration, and represented a well-known flour. The title of the film was "The Cook's Dream," and in it the cook made a cake in the ordinary way with ordinary ingredients, but the result was a sad failure. Tired and disgusted, she sits down and goes to sleep beside the utensils, and, while she sleeps, a girl, wearing a check apron, comes in, and with the proprietary flour makes a cake with no trouble at all, with smiling cheerfulness, and completes the work in a few minutes. The directions which she followed are thrown upon the screen. This, briefly, is a description of the film, and a little consideration will show how excellent it is. The amusing story holds the attention of the audience, and all through there is expectancy as to what will happen next. Then the girl who comes in while the cook sleeps wears the check apron with which the public have been familiarised in Press advertisements of this particular flour. Her action and its results give a practical demonstration of the value of the flour, and the directions and phrases thrown on the screen drive home the lesson.

Theatre and Concert Programmes. Another advertising medium much used, which is also connected with places of popular entertainment, is the theatre or concert programme, but it is a question whether these are of much value, except for alcoholic drinks, cigars and tobaccos, and similar advertisements. These are the articles that are generally advertised on programmes; and it must be confessed that, so far, the manufacturers of household commodities, the mainstay of advertising, have not used this media extensively. In a general way, programmes are not any too attractive, their form is not suitable for the display of advertisements, the settings are not usually good, and it is a question whether people at theatres and concerts are in the frame of mind in which a lasting impression can be made upon their minds by something that is concerned with their everyday life. They have gone to the place of amusement for relaxation and entertainment, and, despite the fact that they may have to sit waiting half an hour or so for the performance to begin, it is doubtful if they read the advertisements on their programmes, and, if they read them, whether they think about what they read. Anyway, only the spaces round the actual programme should be taken; those on the back are of very little value indeed.

A suggestion has recently been made by Mr. J. Peile that programme advertising can be made much more effective by a change in its form. He maintains that, as people go to theatres and concerts mainly to be amused, the advertisements on the programmes should be cast in a humorous vein, and would then find the people responsive. This is done in France, and there seems no reason at all why it should not be attempted here. The agents for letting space on the programmes would, however, have to take the first step to organise the business, for it would be little better than useless for one or two firms to attempt this. If the services of some able humorous artist, such as Mr. Hassall, were enlisted, and the advertisements systematised, the programme might be saved for its humorous advertising pictures.

Fancy Costumes. While on the subject of popular amusements, another form of advertising may be mentioned. Manufacturers often get applications from people, both male and female, who are going to fancy-dress balls, and wish to go in a costume illustrating the commodity that the manufacturers are noted for. It is not necessary for the manufacturer to have elaborate costumes made up to lend out, but by supplying showcards, cutouts, cartons, and labels he can very often get an excellent advertisement; and if the costume wins a prize, the name of the firm whose goods are represented will probably be mentioned in the local paper. For example, at a recent fancy-dress ball, two costumes represented Chivers' jams and canned fruits, and these were made up from showcards illustrating sprays of fruit and a number of labels with pictorial representations of the various kinds of choice English fruits packed. So excellent was one of the costumes that it took a leading prize. The body of the dress was a grey silk, and the pictures were arranged artistically round it.

Hotel Advertising. A good deal of advertising is done in the large, popular hotels. This is generally effected by means of framed cards over the mantelpieces in the bedrooms, each card being divided up into a number of spaces that are let to advertisers for a period of one, two, or three years, an annual rental or a lump sum to cover the period being charged. It must be remembered that the hotels that do this are not the great, high-class hotels, and therefore the class of people who frequent them are not the wealthy. But for a middle-class clientèle they are excellent, and there is no doubt that the spaces are of considerable advertising value.

The menu-cards in the dining-room and in restaurants are also used as advertising media, though it is a question if these are of much value. The advertisers are usually the firms who supply goods to the hotel or restaurant, and who take the space somewhat in the way of a quid pro quo for the business they receive.

Lantern Lectures and Slides. A good deal of excellent advertising can be obtained by many manufacturing businesses through the medium of the magic lantern. It is surprising that a larger number of firms do not use the opportunity thus provided. A series of slides showing the various processes of manufacture, from the gathering of the raw material to the issue of the finished product, can be prepared at very small expense, and the cost of multiplying sets of these pictures is not great. The slides can then be let out free of charge, any breakages being charged for, and carriage both ways being paid by the borrower. Of course, if the best value is to be got out of this form of advertising, a consecutive lecture must be prepared to go with the slides. The usual plan is to make the matter quite subsidiary to the slides, mere descriptions of the pictures; but not only is this ineffective from the advertising point of view, but it also detracts considerably from the interest.

A thoroughly connected lecture should be written, the pictures coming in merely as illustrations incidentally. The lecture must, of course, be light in style, with a vein of humour, if possible, running through it; and prepared in this style, with a set of about thirty or forty pictures, it will be welcomed by clergymen, schoolmasters, and others, particularly in villages and rural districts that are very difficult to reach with advertising in other ways. The mistake so often made is to give far too many slides in a set. They are rushed through the lantern with the briefest of descriptions, the eye is tired, the mind is confused, and no definite impression is left on the brain, so that the whole lecture, and probably the article whose manufacture it illustrates, is soon forgotten.

Advertising Novelties. A great deal of money is spent by advertisers on little novelties, printed in colours on card and made either in the form of working models, more or less elaborate, or in the form of a game, painting-book, or some other toy interesting to children. These are very good as supports to other advertising, such as that obtained through the Press or poster; but novelties are expensive, their distribution in right channels without waste is not easy, and their advertising value is not very direct. They do little more than give a reminder of the name of a firm or commodity. The usual methods of distribution are through the shopkeepers, by house to house distribution with samples, and through the elementary schools, which are always anxious, particularly at Christmas-time, to get such novelties for the children. A little ingenuity will suggest novelties that need not cost more than a farthing each; and it is safe to say that the less complicated they are, the better they are from the advertising point of view. Elaborate working toys that easily get out of order have a very short life, and they are naturally far more expensive than the simpler novelties, which not only last longer, but, being cheaper, can be distributed on a more wholesale scale.

Useful Gifts. Gifts for distribution need not be confined to novelties of this elementary type. Some businesses find it good advertising to give away in certain quarters more costly and useful gifts, such as pencils, penknives, pocket-books, diaries, pocket-mirrors, etc. And the name of the firm bestowing them should not be too obtrusive on the gift, or it will miss its purpose. Few people care to use a knife or pencil, etc., that is obvious to all beholders as an advertising medium. These useful gifts are usually distributed to shopkeepers' assistants, buyers, and others, and are intended to act as reminders of the firm that gives them. Of this type of advertising medium, the calendar is the most familiar. An enormous number of firms issue almanacks in all forms, shapes, and sizes, from the pocket calendar, the desk calendar, the large or small diary, to the artistic wall almanack printed on card or paper.

From an advertising point of view, the tear-off calendar, with a different sheet for each day, is by far the most useful. On each sheet there can be some fact or phrase about the article advertised; and not only will the changes be rung, but the very fact that the words change from day to day will ensure that they be read by most people who see a use in the calendar. It has been pointed out that while a page in a daily newspaper costing £250 will bring an advertised article before about 850,000 people for one day only, 15,000 calendars, costing the same amount of money, will have a life of 365 days, the circulation therefore reaching 5,475,000.

Household Articles. Of this class of advertising medium is the household article which is given away to advertise some commodity in the consumption of which the article can be used. A salt-sprinkler given by a salt firm, a jam-dish by a manufacturer of fruit preserves, a toothbrush by a tooth-paste manufacturer, a saucepan by a

purveyor of prepared oats, and so on, are actual examples of advertising of this class. The article, of course, bears the name of the firm, and every time it is used it is a reminder of the goods it advertises. It must always be borne in mind, however, that publicity of this kind must not be too evident, or it will defeat itself, for people will not use an article that is too obviously intended as an advertisement.

Other useful articles that are serviceable in shops, such as counter-mats for the cashier's desk, umbrella-stands, water-troughs for dogs, and so on, are a good deal used as advertising media ; and they are quite good, for they serve the double purpose of pleasing the shopkeeper and keeping the particular line of goods before his notice, and of advertising the goods also to the public who go into the shop.

Advertising on Delivery Vans. A form of advertising that has grown up quite recently is that of placing announcements of goods on the sides of delivery vans. Practically all the large firms of carriers now let out van space in this way; and there is no doubt that, in London particularly, the publicity obtained by those using the spaces has been good. But apart from the carrier firms, every manufacturer who has delivery vans of his own will utilise the spaces on the sides for advertising. The announcement will have to be very brief, and in selecting a colour-scheme something original should be sought, though not so original as to be inartistic. Such advertisements, if they are to help and not hinder, must be kept in good condition, being repainted whenever necessary. Nothing is more harmful to a first-class firm than a shabby advertisement. The sides of the van are, of course, the most obvious places for an advertisement ; but it must be remembered that far more people see the front and back of a van as it comes towards them or goes from them than the sides, and therefore there should be a prominent announcement on the shade over the driver, which can be read by those who see the van coming, and a similarly distinctive notice on the back, for the benefit of people after the van has passed them going in the same direction. Further, as there are many millions of people travelling on the tops of omnibuses and trams, who are constantly looking down and cannot see plainly the sides of a van immediately below them, it is worth while to paint an announcement neatly on top. The mere novelty of the thing would attract attention and secure excellent publicity. The wonder is that this has not already been done on a wholesale scale.

Aerial Advertising. Probably the advertising of the future will be aerial advertising. Already a good deal of this has been done by means of fixed balloons, floating banners attached to box-kites, and so on. But the aeroplane opens up endless possibilities in this direction. It can go where it will, always attracts attention ; and if an announcement in large letters is painted on the under side of its wings, it could be read quite easily when the machine was travelling at a low elevation. With the perfecting of aeroplanes the restrictions about flying over towns will no doubt be relaxed, and we may expect a much greater use of the medium than there has been during the past few years. Even more effective than aeroplanes may be air-ships, owing to their larger size; and there is no doubt that the attention of manufacturers and others will soon be turned in this direction.

House Magazines for Retailers. House organs for manufacturers have already been referred to, but it is not only the large wholesale firm or the great manufacturer who may successfully make use of a house organ. The retailer, if he is in a fairly good way of business, may also have his magazine, while even smaller retailers, if they combine together, may run a local magazine that may prove of untold advertising benefit to them all. Their plan would be to form a little syndicate, arranging that each trade—grocer, tailor, jeweller, etc.—should be allowed to participate. There is even room for some enterprising individual to produce a really first-class magazine for localisation by shopkeepers, just as similar magazines are produced for localisation by the Churches. A group of traders in each town could then arrange for the printing of a local cover and insets, with space given up to the advertisements of each. If the magazine was produced in really good style, and had first-rate stories and articles, it might even be sold for a penny, so that the retailers would get some of their money back.

Such a magazine must be essentially a domestic magazine, for it will be read only by the women of the house ; and, of course, it must have pages for the children. One or two large firms in the United Kingdom already issue excellent house magazines on their own account, and recoup themselves largely for the outlay by letting space inside at substantial rates to the manufacturers of proprietary articles. The house magazine may be distributed in the shops of the firm, or, better still, it may be posted, like the catalogues, in envelopes to the addresses of customers and other suitable persons.

The principal forms of advertising have been dealt with briefly, but there are, of course, many other media which have not been touched upon, and these are constantly growing, for with the coming of new ideas and new inventions it is not long before the novelties are harnessed to the purposes of publicity. The advertising man, if he is to be successful in the best sense, must not be one who merely does what others have done before him, however well he may do it, but one who is always on the look-out for fresh sources of publicity, and who—at times, at any rate—is the first in the field. The status of advertising is certainly being raised, and its vital importance was never so realised as it is today. That importance will grow with the years, and there is no doubt that in the future there will be more, not less, publicity.

Entering the Advertising Profession. In view of this, it may be interesting, in conclusion, to say a word or two as to how the profession of advertising may be entered. Like journalism, it is a profession for which a man—or a woman—must have a natural instinct ; and just as the successful newspaper man will have "a nose for news," so the successful advertising man will see in all kinds of incidents and happenings an opportunity for obtaining publicity. But apart from this, there are, of course, certain routine matters that have to be learnt by practice; and the best thing a young man who has ambitions in the direction of advertising management can do is to seek a position on the staff of a firm of reputable advertising agents, or in the publicity department of a large manufacturer. Even if he desires to take up the newspaper side of the work, a training in an advertising agency will be of inestimable value.

CHARLES RAY

ADVERTISING CONCLUDED—END OF GROUP 12

Veneering. Inlaying. Furniture Construction. Table Tops. Carcases. Fitting of Shelves, Backs, and Tops. Framed Work. Staining and Polishing.

CABINET-MAKING

No sharp distinction can be drawn between cabinet-making and joinery, any more than between carpentry and joinery, though in each case it is easy to give specific instances of work that is within the exclusive province of one or the other. Joinery occupies an intermediate position, and is overlapped at one extreme by the rough and heavy work of carpentry, and at the other by the fine and neat work of cabinet-making. Such work as plain furniture, and shop, bank, and office fittings may be done either by cabinet-makers or joiners, the choice depending chiefly on the degree of finish required. With the exception of plain deal articles the construction of furniture is regarded as cabinet work. With a few exceptions the tools employed and the methods of jointing have been described in the courses on Carpentry and Joinery.

Woods Employed. In cabinet-making, hard wood is chiefly used, and the soft varieties, in which the bulk of carpenters' and joiners' work is done are generally used only under veneer and frequently not even then. A great number of fancy woods are used, but for large articles the list is very much reduced owing to the unsuitability or cost of many of the rarer woods. Mahogany is the most commonly employed and is one of the best for furniture, owing to its small liability to shrink and warp. For many years after it came into general use it was to the cabinet-maker what oak was to the carpenter, and what deal is to the latter craftsman at the present time. There are two main varieties, the Spanish, which is valued for its rich appearance and hardness, and the Honduras, or baywood, which is softer, straighter grained, lighter in colour, and cheaper. The chief other woods used are oak, walnut, ash, and birch. The important woods have been described in the chapter on the Strength and Use of Timbers, beginning on page 211. Soft woods, such as pine and American whitewood, are used a great deal for parts that do not show, such as backs of carcases and drawers, drawer bottoms, runners, and sides. They are used also covered with veneer, or in some cases—drawer bearers, for instance—may have a hard wood facing about ½ in. thick, glued on the front. All wood in cabinet work must be thoroughly seasoned. Artificial drying in kilns is usually resorted to. There are many varieties of these.

Furniture Designing. This is not done by the journeyman cabinet-maker, but by specialists, who make the drawings for him to work from. These drawings are usually not very elaborate compared with the drawings required in some other trades, for exact dimensions are unimportant, and many details of construction can safely be left to the judgment of the workman or his foreman. A single perspective view of an article with its leading dimensions is therefore often sufficient for a cabinet-maker to work from, and in some cases no drawing at all is made. Drawing is supplemented a great deal by written instructions. The designer must be familiar with methods of construction, or he will cause needless trouble and expense, with perhaps weak and unsatisfactory results. Apart from this, he is chiefly concerned in designing goods that will best command a sale. So much variety has gone before that new designs now are new combinations of features of old designs. It might be quite possible to design something absolutely new, but the demands of utility and good appearance would almost certainly condemn it. The first essential in any article of furniture should be a design which makes it convenient for use. All ornamentation and considerations of appearance should be subsidiary.

The Value of Appearance. In cabinet work appearance has to be considered more than in other woodworking trades, and though utility should never be subordinated to it, it makes a difference between the work of the cabinet-maker and that of the joiner and carpenter. Good work is desirable throughout in an article of furniture, but only parts that are constantly visible are finished neatly, while backs and under parts are left rough. Another thing peculiar to cabinet work is that strength is in most cases of less importance than appearance. Furniture is not supposed to be subject to rougher usage than when serving its normal purpose, and the cabinet-maker constructs it on that assumption. In the jointing of light framework, for instance, stub tenons or dowels secured by glue alone are typically cabinet work. In many articles, however, the appearance of strength is desirable, and thus we have pilasters formed by gluing thickening pieces against thin sides, and the lining-up of horizontal pieces, and addition of solid-looking plinths and cornices. In some cases the purpose of an article permits of great latitude in fixing dimensions, and then proportions are adopted which look well. Thus an article of rectangular shape is not made more than twice as long, or high, as it is wide.

Changing Fashions. The design of furniture is subject to slow changes of fashion. As with dress, and other things, the style of which changes without necessarily improving, this is caused by a desire for distinction among wealthy people and desire among poorer ones to imitate them, a new fashion being adopted by the former as soon as the reigning one has become common property. Besides this, public taste varies at different periods, and the style of furniture varies correspondingly. It is possible, however, that the changes of the future will be slight compared with those of the past, because extremes in all directions have been reached and recognised as unsatisfactory. The best furniture is made primarily to serve its purpose perfectly, and secondly, to please the eye. The highly ornamental and the severely plain, alike, generally fail in both these directions.

A complaint frequently made is that furniture is less substantially made than formerly. The assertion is less true now than it was some years ago, but the time has gone past when quality and methods did not vary much from a set standard. If the best work now is not superior to any that has ever been done before, it is because better work is impossible. No one can dispute that a great deal of modern work is trashy, but as such work does not last we have no

means of knowing whether the workmen of a century or more ago were equally skilful in that direction. Probably they were not. The rank and file, no doubt, were ignorant, simple-minded men in a position to take as much time as they pleased to do anything. They had a high opinion of their manual skill, and exaggerated notions of the importance of trade secrets, in many cases not to be imparted freely to each other, and still less to the outside public. Modern conditions are different. Work is done now much more expeditiously and consequently at comparatively far lower prices. In many cases the cost of labour is a trifle compared with the cost of material. This is not because wages are low or because manual work is done more rapidly than formerly. It is because the workman now is assisted by machines which perform all the operations that before occupied most of his time. The subdivision of labour now prevailing also conduces to rapidity of production.

Old and Modern Work Compared. Neither machine work nor subdivision of labour means inferior work, but rather the contrary. In some respects the best of the very old work was rough compared with the best modern work, and its roughness was not compensated for by its being any stronger than what is made now. We have only to notice the construction of old furniture preserved in museums to perceive that. Articles elaborately carved and inlaid are often jointed more roughly than would be permissible now. The use of wood pegs in tenoned joints, with the end grain of the pegs showing in the front faces of the work, and generally projecting about a sixteenth of an inch through shrinkage, would be intolerable in the cheapest modern articles. Old work suffered also through being done by men who were not specialists. There are few men who can do both heavy and light work with equal accuracy, and no one man can be as skilful at half a dozen classes of work as the same number of specialists assisted by machinery can be.

The Element of Time. If it be untrue to pretend that our best is not equal to the best that has gone before, it is still more untrue to suppose that our men are not equal to their predecessors. Only those whose admiration for the past is based on unreasoning sentiment can believe so. So far as we can judge of them, there is no reason to doubt we not only have their equals, but have far greater numbers of them. But in most work nowadays the element of time has attained an importance it never had before. Most classes of work are so often repeated that the time they should occupy is known or can be estimated almost to an hour, and it is to the workman's discredit if he exceeds this almost as much as scamped work is to his discredit. The test of a first-class workman is to do work of the best quality in the minimum time. If an unlimited amount of time is allowed, a far less skilful man can equal the product in quality. A first-class workman, however, has not always the opportunity to do the best work. Quantity instead of quality may be required of him. There is a large demand for cheap articles, the cost of which is cut down by employing inferior material and quicker methods of construction. Their unsubstantial character does not indicate that they were made by incapable workmen, but that their cost was not allowed to exceed a certain amount. Work of this kind is justifiable because it supplies a demand, but in the case of the cheapest work it may be doubted whether the demand would be very great if the average purchaser were capable of seeing its defective character.

Modern Subdivision of Trade. Cabinet-making, even more than most trades which have attained a high degree of development, is very much subdivided. It has first of all two natural divisions, for there is a decided difference between carcase work, such as wardrobes, chests of drawers, etc, which are boxed in, and open framework, such as that of chairs. Chairs are so different to ordinary cabinet-maker's work that people employed in their construction are known as chairmakers, and not as cabinet-makers. Chairs differ so much from each other, however, that the chair-making industry is itself very much subdivided. But even among articles of furniture which do bear considerable resemblance to each other, it is found more economical for firms to confine themselves chiefly to one, and portions of that are often purchased ready made. In no case is all the work on one article done by one person. All turned parts are done by a wood-turner. Carving is done by a carver or by machinery. Veneering and inlaying are done by specialists. Polishing and upholstering are done by men of those trades. Among the operations just mentioned the only ones that can be considered as branches of cabinet-making are veneering and inlaying.

Veneers. These are thin sheets of fancy wood ranging in thickness from that of a thin sheet of paper to $\frac{1}{4}$ in. They are used a great deal in cabinet work, and to a less extent in joinery, for gluing to the surface of cheaper wood to improve the appearance of an article. In some cases also curved parts are built up entirely of veneer by gluing a number of thicknesses together. *Ply wood*, which is now largely used for panels and drawer bottoms, is built up in the same way with the grain of the layers crossed. These, however, are not veneer in the ordinary sense, but plain cheap wood sawn thin. The most expensive furniture woods, and especially pieces of exceptionally handsome appearance, are seldom used for anything else but veneer, for it would be considered a waste of valuable material to use it in any other way unless for articles so small that the amount of material used in them is not worth considering.

Veneer is cut by special machinery, and comes into the cabinet-maker's hands ready for use. It is known either as *knife cut* or *saw cut*, according to the method of cutting it to thickness. By the knife-cut process it can be cut very thin, and there is, of course, no waste in sawdust. From 30 to 40 thicknesses may thus be obtained from 1 in. By sawing, about one-third that number is the most possible, but sawn veneer is thicker and for most purposes, better, though more troublesome to glue. Saw-cut veneer as used for most purposes is about $\frac{1}{16}$ in. thick. Very thin knife-cut is sometimes backed with paper. This prevents it from splitting and warping. Warped veneer may be flattened by damping and putting under pressure between warm, dry boards. Knife-cut veneer may be either sliced or rotary-cut in a kind of lathe. The log is steamed or boiled before cutting, and the cutting machinery is very heavy and rigid, so that a sheet of tissue paper thickness can be cut if desired.

Veneering. The methods of gluing veneer differ in some respects from those of making ordinary glue joints. This is owing to the thinness of the veneer and the large surface to be glued. There are two methods; one by means of *cauls*, which practically means cramping the parts till the glue is set. The other by the use of the *veneering hammer*, which means squeegeeing surplus glue out by sliding pressure on the veneer, and the latter in such cases is always so thin that it remains

in contact without further treatment. This latter, however, is considered only a makeshift method, to be employed when cauling is inconvenient.

The wood on which veneer is to be laid must itself be carefully chosen. A hard close-grained wood does not adhere well to a soft one. Soft woods, such as pine and American whitewood, are very commonly used beneath veneer, but in the best work Honduras mahogany would be employed as a groundwork. Knots should be cut out and pieces of ordinary wood fitted and glued in their place. Small holes should be filled with plaster of Paris. The surface, after being planed, is roughed with a *toothing* plane and sized with thin glue. A toothing plane iron is shown in **1**. It fits nearly vertically into a plane body resembling an ordinary smoothing plane. The serrated edge of the iron scratches the wood and leaves a surface on which the veneer is not liable to slip and the glue obtains a good hold. Two toothing irons of different degrees of coarseness should be kept, as a finer iron is needed for hard wood than for soft. Another method sometimes adopted is to go over the surface with coarse glasspaper on a flat rubber. The veneer is toothed also when sufficiently thick. Rounding surfaces are rasped and roughened with coarse glasspaper. Where a piece of board is cut tangentially to the annular rings of the tree and only one side of it has to be veneered, the veneer should be laid on the heart side, as in **2**.

Veneering with the Hammer. The veneering hammer is used as in **3** and **4**, to press out surplus glue. The hammer has a handle about 1 ft. long and a head about 6 in. square by $1\frac{1}{4}$ in. thick, with a piece of thin iron inserted in a saw-cut in its lower edge and secured by screws. The edge of the iron, which is used to press the veneer, is rounded slightly and made smooth so as not to injure the surface. In addition to this, soap is often used to enable the hammer to work freely without sticking. Hot water is also sparingly applied to the upper surface of the veneer, chiefly to counteract the tendency to curl when it is wetted by the glue on the other side. The glue is spread as rapidly as possible on both the ground and the veneer; the veneer is laid on the ground and pressed down, and then the hammer with heavy pressure on its head is worked about the surface to force as much glue as possible from the centre out to the edges. The easiest way to move the hammer when pressing on it is to work the handle from side to side while moving it forwards or back, thus giving the head a zigzag movement over the veneer. The veneer, as a rule, will remain in close contact after the hammer has been passed over it, but sometimes blisters may be seen or detected by tapping. In such cases the glue beneath may be remelted if necessary by the application of heat, which soon penetrates the veneer. A hot flat iron is generally kept ready for this purpose, and a damp cloth first laid on the place where it is to be applied. The blister will then generally remain down or if it is obstinate a weight may be put on it for several minutes. A bowl of hot water is placed on the bench when the veneer is to be laid, and the hammer, when not in use, is put in the water to keep its edge free from hardened glue. A sponge and one or two pieces of cloth are kept in the water, too. The gluing must be done in a warm atmosphere free from draughts, and the glue applied as hot as possible, so that the veneer may be properly laid while the glue is still quite liquid. Veneer can be removed if necessary by the application of heat and oil or water to loosen the hold of the glue, but it is never worth while to do this, as the veneer would be practically spoilt in the process. Bad places in veneer are better rectified by cutting them out and fitting other pieces in. A piece with grain as nearly like it as possible should be laid on top, and an irregular cut made through both, following the grain as much as possible to make the joint unnoticeable. An inlaid piece cut geometrically square or circular is much more conspicuous. Air can be released from a blister if necessary by making a small puncture. If more glue is required beneath, a slit must be cut with the grain.

Veneering with Cauls. A caul is a piece of wood, zinc, or other material, of the size required to cover the surface to be veneered. It serves two purposes. One is to contain heat to make the glue run freely when it is cramped on. The other is that, veneer being too thin to have any rigidity in itself, uniform pressure must be applied all over its surface, and cramps alone would not do this. When a surface is large, its area may be covered equally well by a number of cauls placed side by side. For curved surfaces, cauls shaped to fit the curve are required, but in most work surfaces are flat, and the cauls are flat pieces of wood of about 1 in. to $1\frac{1}{2}$ in. thick, sometimes kept specially for the purpose, sometimes selected from the stock of wood used for ordinary work. For permanent use they are better covered with sheet metal, preferably zinc. This not only preserves their edges from wear and reduces the risk of splitting and warping, but glue from the veneer does not obtain a hold on it, and consequently it cannot get stuck to the work, as is sometimes the case with wood cauls, for glue makes its way through thin veneer. Another reason why metal is preferred is that cauls have to be heated before they are applied, and, if care is not taken, the wood ones are liable to get spoilt through burning. Neither do they retain heat as well as metal cauls. Small cauls may be merely plates of zinc $\frac{1}{4}$ in. to $\frac{3}{8}$ in. thick. Large ones are backed with wood. Cauls of irregular shape, and consequently troublesome to make, are, if constantly required, usually made of cast iron. For temporary use a bag of sand may serve as a caul on a surface of any contour, and may be heated and cramped on the veneer. Cauls are cramped to the surface by any convenient method.

For small work, hand screws are generally used [**5**], and, as in using the hammer, pressure should be applied first to the central parts to force the glue outwards to the edges. In **5**, two pieces are veneered with one caul between them. Wood cauls should always be soaped to prevent their sticking and pulling pieces of veneer away. Zinc cauls are soaped also when working with very thin veneer. In using cauls, only the dry heat of the caul is employed, and therefore the work is dry and hard in much less time than is required for hammer-laid veneer, in which the surface is wetted with hot water. The cauls and cramps are left on for several hours, until the glue is set. For work on a large scale, metal presses [**6**] with powerful screws are used, and a number of boards with veneer on are put in a pile and very heavy pressure applied, a number of presses, about 6 in. apart, being used to press long pieces. The boards are passed through machines which apply the glue very rapidly. For work on a small scale various kinds of wood presses are made by the workman, the principle being similar to the iron press shown, but wedges, instead of screw power, are the usual method of applying pressure. Joints and cracks in veneer are kept together and the glue prevented from coming

through and sticking to the caul, by pasting paper or canvas over. In some cases it is a practice to cover the entire face of veneer with paper. This is cleaned off after the cauls are removed.

Veneer is cut to dimensions by laying it on a flat surface, using a straightedge on it as a guide, and cutting with a sharp chisel or knife if the veneer is thin, or with a saw if it is thick. Joints on a surface are made by lapping the edge of one piece over the adjoining one, and then by cutting through both. Veneer should always be put on larger than required, and the edges trimmed off afterwards, otherwise there would be trouble in setting it correctly into position while gluing. The best veneer is generally put on panels, because the figure or grain of the wood is more noticeable there than on narrower parts. Often they are *cross veneered*—that is, a plain piece of veneer is first put on across the grain, and this is afterwards covered by the final veneer with its grain running the same way as the *ground* or *core*, as the interior wood is called.

Veneers on panels and other large surfaces are sometimes cut and jointed geometrically, pieces cut out from the same log being turned with grain reversed towards each other, so that similar curls and twists incline to the joint from opposite positions. Parts may be stuck down and pieces fitted in to make bad places good, as described for hammer-laid veneer.

The Scraper and its Use. The scraper is a small piece of sheet steel about $\frac{1}{32}$ in. thick. Its usual form is rectangular, measuring about 6 in. by 3 in. Often a greater length and less width is found convenient, but in any case its original dimensions soon become reduced by wear. Other forms are curved to suit hollow or round surfaces. Its edges are made very keen by first squaring and then slightly burring or turning them over, as shown to an exaggerated extent in **7**.

The scraper is a tool frequently used by joiners, but to the cabinet-maker it is indispensable, and is used after the plane on almost all surfaces. The hard wood used by the cabinet-maker is often too cross-grained to be planed at all without tearing up the surface and leaving it worse than when sawn. But even when it can be planed smooth, the marks of the plane show as a series of undulations across the surface, and although these might be removed by glasspaper on a rubber, it would be difficult to produce as smooth a surface as can be done with a scraper in less time. The scraper, therefore, generally follows the use of the smoothing plane and is itself followed by a rubbing down with very fine glasspaper.

The scraper is held and worked at an angle as in **8** and **9**, so that the sharp edge can be made to scrape or cut a very fine shaving when moderate pressure is exerted. Sometimes the steel is fitted into a wood block which serves as a handle [**10**.]

The sharpening is effected as follows: The edge is first ground or filed square and straight with a very slight amount of rounding up at each end, so that the corners will not leave ridges on the surface of the wood. Next, while still keeping the edge square, it must be made perfectly smooth. The best way to do this is by rubbing it on an oilstone [**11**]. The edge must be rubbed with the scraper vertical on the stone, and each face must also be rubbed [**12**] to remove the ragged burr which gets turned over in grinding and smoothing the edge. The edges should now be square and smooth with sharp angles. It is necessary now to burr or turn these angles uniformly so that they shall be very much keener than they are at 90°. This may be done with the scraper in either of the positions shown in **13** and **14**. Another way is to hold the scraper in a vice. A short rod of steel in a handle is the proper tool to turn the edge with, but very often the back of a small gouge is used for the purpose. In **13** the scraper is shown held in a vertical position with its lower edge resting on the edge of a bench. In **14** the scraper is laid flat on the bench with the edge to be sharpened projecting slightly over. In both cases the sharpener is held at a similar angle in relation to the edge of the scraper. With the sharpener slightly tilted as shown, and pressing as heavily as possible, it is drawn sharply along the edge, turning over a slight burr as it goes. This burr is imperceptible to the eye, but is sufficient to scrape a wood surface far more effectively than would have been possible before this operation. If sufficient pressure is applied, one stroke of the sharpener is enough, but if not, more may be made. The edge soon becomes dull with use and requires re-sharpening, and after this has been repeated a few times, the edge becomes so worn that it is necessary to re-grind. In re-sharpening, the turned edge is generally rubbed flush, as in **15**, before the sharpener is used to turn the edge afresh. All the edges of a scraper may be sharpened in this way so that each can be used in turn till too dull to cut.

Inlay. The inlaying of ornamental design into a surface is frequently practised to decorate cabinet work. To a person unacquainted wth the practice it might be supposed that the effect was obtained by staining or painting the design on the surface. The difference in colour is obtained by the use of different woods, and in a few cases, where such colours as blue or green are employed, by staining the inlaid wood before insertion. Wood is the chief but not the only material used as inlay. Others often employed are ivory, pearl, tortoiseshell, and metal. It is then called *buhl* work. The inlaid material is always very thin and is glued in place. This is more frequently done in veneer than in solid wood, and the thickness of the veneer usually represents the depth to which the pattern is inlaid. The forms of inlay range from simple straight lines of white or black wood about $\frac{1}{16}$ in. wide, round the edges of surfaces, to representations of flowers and scenery. Figure **16** is an example of stringing and banding round the margin of a surface. The term inlay includes all inlaid work, but different names are given to different classes of inlay. Work of complicated outline, such as representations of natural scenes and highly ornamental patterns, is known as *marquetry*. Geometric patterns are called *parquetry*, and this term is now applied chiefly to floors laid with hardwood blocks arranged in any geometric pattern. *Intarsia* is a very simple kind of marquetry in which pictorial effect is obtained by a few pieces of inlay, the grain and outline of which represents a land or sea-scape without detail. Buhl work, as already noted, is inlay of other material than wood.

Methods of Inlaying. Inlaying of the more complex character is not done by cabinet-makers, but panels or other parts are purchased already inlaid, or inlaid veneer is purchased and either laid on large enough to cover the surface it is required for, or the inlay is contained in a small piece of veneer cut to oval, circular, or other shape, and let into the body of the other veneer. Patterns of plain outline are also sold separately. Built up patterns and inlaid veneers when purchased in this way have their parts united by being stuck on a backing of paper. This is the usual method of forming patterns even when done by the person

who afterwards intends to inlay them in another surface. The paper is intended to be on the outer side when the pattern is inlaid, so that it can be cleaned off when the glue is set. If turned the other way the paper would prevent the glue from holding the inlay properly, for paper can easily be split if glued between two pieces of wood.

Fitting Inlay into Veneer. There are two methods of fitting the parts of patterns together and fitting inlay into veneer. One is to cramp or stick temporarily the pieces face to face, and cut through both with a fine saw or sharp knife to the outline required, thus obtaining an interior part which will fit into a corresponding exterior one. The other is to cut a pattern out separately, and lay it on the surface in which it has to be sunk, and mark its outline with a sharp pointed knife or scriber, and cut out to these lines. For inlaying into solid wood, this latter is, of course, the only method. Incision is made to the required depth by chisels, gouges, or a knife with a sharp point, and the recess for the inlay routed to the required depth, with a small *router* if in solid wood, or with a chisel when only veneer has to be removed. A router is a plane which can be set to cut a channel or recess to uniform depth. It will be illustrated farther on. But most of the inlaying the cabinet-maker is required to do is the insertion of plain parallel strings, the channels for which can be cut very rapidly with a double-toothed cutting gauge, similar to a mortise gauge, except that the cutters are deep and thin, to penetrate well into the surface. This gauge is set to the width of the inlay, and makes two parallel cuts in the surface at the required distance apart. The material between these can be removed at a stroke with a router. The inlay is glued in, and pressure put on it till the glue is set. The inlay may be parallel strips cut from veneer, or more frequently it is bought ready cut into strips known as *strings* or *stringing*. Mosaic bandings are also often employed. These are made up in innumerable patterns of different woods arranged in different ways. They are made by gluing up the patterns in lengths and then slicing off in strips about $\frac{1}{16}$ in. thick or less. The grain must run plankwise with the surface when the inlay is glued in place. Inlay designs are nearly always made in quantity either by gluing up a thick pattern and slicing off, or by sawing out a number of thicknesses together. In either case it is not regarded as cabinet-makers' work.

Other Methods of Ornamentation. Next to mouldings, which have been treated of in Joinery, carving is the most important of all decorative methods. Carved portions of work come into the cabinet-maker's hands already finished by the carver, and he is concerned only with fixing the parts in place or fitting them together. The same is true of turned work, which is done by wood-turners. This is generally not intended chiefly as ornament, but it is so easy to make turned work ornamental that it is done even in the simplest and cheapest work, almost the only exception perhaps being the use of plain parallel rods in some chairs and other articles. These, however, are not turned in the ordinary sense, but made cylindrical by being passed through a machine with revolving cutters. Another form of ornament on furniture is known as *ormolu*. This consists of metal ornaments with gold plated or gilded surface, attached to the wood by brass pins or fine screws. *Fretwork* occupies a position of some importance in light fancy articles of furniture. In this very fine saws are used to cut ornamental patterns in thin wood. The lines to cut to are transferred from patterns on paper. Fretwork for the cabinet-maker is cut by machine saws and comes into his hands ready to be attached to the work. *Pyrography*, or *poker* work is a rough means of ornamenting a surface by tracing a pattern on it with a red-hot platinum point, which burns the required outline, making a slight channel in the surface of the wood, and showing as brown or black lines according to the degree to which it is burnt.

Furniture Construction. The method of constructing a given article may vary with circumstances. If the work has to be done as cheaply as possible without much regard for quality, the parts are prepared and put together in the simplest style, glue and nails being the chief means of union. If the best work is required the best forms of joints are adopted everywhere instead of the parts being allowed to depend solely on the medium which holds them together. The quality and amount of material used may also vary. Soft wood is cheaper than hard, does not look so well, and is less durable. Pieces of wood, alike in kind, vary in quality and strength. Thin material may be used for economy when thicker would be more suitable, or the strength of an article may be diminished by economising material in hidden parts. There are, of course, some exceptions where cheapest and best work must be done alike, because there is no other practicable way. The arrangement of the parts of an article of furniture has to be made with a view to exterior appearance, economy of material and labour, and sufficient strength to serve the intended purpose.

Dowels are employed more in cabinet work than in joinery. They are used very often instead of tenoned joints. Figure **17** is an example. In many cases it is troublesome to get the centres of the holes for them marked correctly by measurement or by gauging from an edge, and then other methods may be adopted. One very convenient way is to locate them by means of pin marks, as in **18**. Ordinary pins are placed in the joint, and pressure applied so that the pin heads leave imprints on both parts, which serve as centres on which to bore the dowel holes. Another method is to have a number of centre pops [**19**]. These might be made of wood with a steel point inserted, but are better turned in solid metal. The body is the same diameter as the dowel, and is intended to be inserted in the dowel hole, which has first been bored in one of the pieces to be dowelled. The thin flange shown at the top prevents if from going farther in. The other piece of wood is then adjusted in position, and a tap with a mallet, or a little pressure, causes the point in the centre to leave an impression corresponding exactly with the centre of the hole required in the other piece. Another method is to cut a piece of paper to the shape of the jointed surface and prick holes through at the places where dowels are required. The paper can then be laid in position on each surface, and the centres marked through the holes in the paper. Another way seldom practicable in cabinet work is to cramp the pieces of wood together and bore entirely through one piece into the other.

Insertion of Screws and Nails. Screw and nail heads are seldom allowed to show on exterior surfaces. Where possible they are put in from behind as described in joinery. Screws with rounded heads are preferred when the heads cannot be concealed. In some cases screws with flat heads are provided with metal cups which give a neater appearance. Nails are punched below the surface with a hammer and punch [**20**], and the holes filled flush with wax stopping coloured to

suit the wood or stain. Figure 21 shows a method of withdrawing a nail without injuring the surface of the wood. The blade of a square or other sheet metal is laid on the surface to receive the leverage of the pincers, and so prevent the wood from being bruised. Figure 22 shows how screw holes may be countersunk by scooping out with a gouge. This is not quite so neat a method as with a countersink bit, but is more expeditious, and is frequently adopted. Needle points are used for attaching light mouldings and other parts. They are similar to ordinary needles, but without eyes. They are driven in the required distance, and then snapped off flush with the surface, and, of course, are then almost invisible.

End grain appearing flush with a surface plank way of the grain is objectionable, and therefore tenons are seldom carried through unless at the back of an article where they will not be noticeable. Even under veneer through tenons are objectionable, because a slight amount of shrinkage causes them to bulge the veneer. In other cases end grain is generally allowed, if possible, to project beyond to avoid a flush joint. Except when they are glued, flush joints are always objectionable, even when the grain of each part corresponds, and consequently they are usually beaded, or moulding is attached to conceal them. The shooting board is used a great deal by cabinet-makers. Small pieces of wood are often sawn, and planed with the tools in an inverted position as in 23 and 24, the saw or plane remaining stationary and the wood being worked backwards and forwards.

Construction of Table Tops. The tops of tables, counters, sideboards, bureaus, etc., are frequently thickened or lined up at the edges, as described in Joinery; but there are several methods of building up the main surface. The simplest way is not to build up at all, but take solid board of the required length and width, and keep it flat by its attachment to the framework of the article, while at the same time allowing it freedom to shrink or swell without splitting. If very wide, this is usually done by buttoning. Comparatively narrow widths may be screwed or nailed with safety, but glue should never be used except in cases where the grain of the parts it is attached to is arranged in the same direction so that all these parts, if well seasoned, when put together can be relied on to shrink or swell similarly. Another method of keeping a top flat is to dowel or tongue flush cleats to the ends, generally with mitred corners. This is satisfactory if the wood is well seasoned, and the width not very great. A better way is to frame and panel the top with a flush panel as in 25. Here also the corners are better mitred, and the joints strengthened either by tenons or dowels. Another method is to half-lap the joint and mitre the upper face only.

The tops of writing-tables panelled as in 25 generally have the panel slightly below the surface of the frame, so that leather or cloth can be glued on the panel to make a flush surface. When solid tops are covered with leather, the border round the leather is veneer glued on. Veneered tops should have their edges corresponding in appearance with the veneer, so that it looks like solid wood, and as edges are generally moulded, and therefore difficult to veneer, the top is built up as in 26. A core of pine or cheap mahogany has an edging of more costly wood, corresponding with the veneer, glued round it, end grain pieces frequently being put on the ends. Both the upper and under faces of the core are generally veneered, so that the core is entirely enclosed. In such cases it is very often cross veneered, as in 26. Another method is to frame as in 25, making the frame of, say, mahogany or walnut, with a pine panel, and to cover this with veneer to match the frame, the veneer generally standing its own thickness above the surface of the frame, as in 26. Another way is to put a hardwood edging with mitred corners round a pine frame and conceal the latter by covering with veneer or leather.

Carcases. Carcases may be either panelled or plain boarded. Sometimes a skeleton framework of posts and rails is built to attach the panels or boards to, and sometimes there is no such frame, but the parts are fitted together at the corners in box fashion, either dovetailed, tongued, and grooved, or, in some cases merely nailed or screwed or secured by glue blocks. The method depends to a large extent on the character of the article. In cabinet work, parts are sometimes panelled mainly for appearance. Carcases intended to stand on the floor, without legs, usually have a few inches of plinth below the baseboard of the carcase. In heavy articles of furniture this plinth is sometimes separate, the carcase merely resting on it; but in most cases the sides of the carcase either extend below the baseboard, and the plinth is screwed against them, or the plinth is partly against and partly beneath, and secured by glue blocks or screws or nails.

A simple example of a carcase is shown in the bookcase [27], the frame of which, with plinth and cornice removed, would consist of two plain uprights with shelves fitted between. The uprights should, to make the most substantial job, continue to the floor, and the plinths be nailed or screwed against them from the inside, the plinths being simply an increase in the thickness of material at the sides. The plinth along the front would have the edges of uprights and bottom shelf to bear against, and would be secured by glue blocks in the interior angles. A plinth at the back would be treated similarly, but generally plinths and cornices are carried only round front and sides, leaving the back a plain flush surface. The cornice is built up by first covering the top ends of the uprights with a plain board, overlapping an inch or so at ends and front, and then fitting moulding beneath this attached in the same way as the plinths, by nailing the end pieces and blocking the front. The objection to gluing the ends is that the grain crosses. So far the constructive details have been illustrated in Joinery, but an important matter to be considered now is the attachment of shelves to uprights.

Methods of Fitting Shelves. There are a number of ways of fitting shelves, and, as a rule, in cabinet work they must be fitted securely without exterior sign of how it is done—that is, without nails in the ends, on cleats beneath, or rebates showing at the front. Shelves for books are often made adjustable, but at present we are considering fixed shelves of all kinds, including bearers and runners for drawers. In an article with plain shelves fitted to plain sides, as in 27, the shelf ends would be rebated into the sides by one of the methods shown in 28, A, B, C. The grooves in the sides, however, are stopped about ½ in. short of the front, as in 29, and the shelf ends notched to correspond. The shelves are inserted from the back. A plain rebate or housing, as at A in 28, affords satisfactory support for the shelf, and is more easily made than the dovetailed grooves at B and C; but the advantages of the latter are that they tie the sides and keep them tightly up to the shelf ends. Ordinarily, however, the plain housing, as at A, is used, and the sides are secured at top and bottom; 30 shows how these housings are cut. At the right-hand end of 30, a tenon saw is being

used to cut the depth, an inch or so at the front having previously been cleared out with a chisel to allow the saw to work. At the left of **30** a router is being used to cut the groove to a uniform depth. Generally, a chisel would be used first to clear most of the material out. A rebate plane might be employed in a long groove, instead of a router, but the fore part, which could not be touched by the plane iron, would have to be finished with a chisel.

The top of the bookcase in **27** would in most cases be nailed on, and the bottom shelf might be nailed as the plinth would afterwards cover the nail heads, but this could be avoided by the use of glue blocks beneath, and generally the ends of this shelf would fit in veed grooves and be glued.

Methods of Fitting Drawer Runners. Figure **31** represents a case or pedestal with runners and bearers to receive drawers. This is an example of sides tied at top and bottom, and requiring only plain grooves for the runners. At the bottom a complete frame stub-tenoned together is screwed or nailed into rebates, which may run right through to the front, as the front edge, and also the screw heads at the sides, are afterwards concealed by a plinth. At the top, *stretchers* are dovetailed in. The intermediate runners are then not required to play any part in tying the sides, but are slipped into plain rebates. Details are shown in **32** of a grooved side, and a runner with its tenon to fit into the bearer in front. The inner edges of runner and bearer are shown grooved, as would be the case if a panel or dustboard was to be inserted between drawers. Figure **33** shows another method in which the side of the article is not grooved for runners, but recesses are cut instead to receive the ends of the bearers at the front and the back ends of the runners at the back. In a few cases bearers are tenoned completely through sides, but, as a rule, a shallow recess only is cut. A rail or bearer connecting the back ends of a pair of runners is not necessary unless to serve as a tie to the sides, or stiffen a back. Runners are often made of oak or other hard wood, which will not get worn very readily by the drawers sliding on it.

Attachment of Backs and Tops. Backs are tongued into a groove as in **34**, or fit into a rebate, as in **35**, or in rough work are simply nailed on the surface. A back may be simply a plain, thin piece of wood, or it may be framed and panelled, or a middle course is to make it as in **36**. In **36, A**, it fits in grooves at the sides, but is not enclosed by top and bottom rails as panels would be. The muntin in the middle is screwed or nailed to top and bottom of the carcase, but the boards in the grooves may be left free to contract or expand. Figure **36, B**, is a modification of this, and is very commonly adopted. Instead of the edges of the thin boards fitting into grooves as at A, they are kept in position by one or more rebated bars, as shown at B. The thin pieces, as well as the bars, are generally nailed to the carcase.

Tops may be simply nailed on, or dovetailed in, or screwed from beneath, or fitted on to a dovetailed tongue, which may be nailed on the ends, as in **37**. In all these cases, when the grain of top and sides coincide, glue blocks may be used also, if there is no objection to their presence. In most cases tops lap over, as in **37**, but when the ends have to be flush, the best way is to dovetail them in with lap dovetails, which do not show on the sides. When tops are screwed on, the screws are usually put from beneath through stretchers, which themselves are lap dovetailed in, as in **31**.

In **38** we have an example of carcase work first framed and afterwards covered as required, the boarding being attached by screws put through from the inside. It represents the skeleton carcase for a chest of drawers. All the material in the framework is, say, 1 in. thick. The boarding at the ends would be, perhaps, $\frac{3}{4}$ in.; the back $\frac{1}{2}$ in., or less, and the top 1 in. As the sides of the frame are to be covered, there is no objection to carrying the tenons through the uprights, and screwing the side and back uprights together as shown. The runners are tenoned at front and back, and notched into the side uprights. The ends of the longitudinal rails at the top are dovetailed to the tops of the uprights. The uprights at the front are, say, 4 in. wide, and all the other parts 3 in. This framework is, of course, equally suitable for attaching panelled sides and back to.

As an alternative to grooving, panels in cabinet work are sometimes inserted as in **39**, a rebate being planed or a bolection moulding glued on the front, and a fillet bradded round the back to keep the panel in.

Figure **40** is a face view of a frame for a panelled side or end showing how the bottom rail is kept above the floor. The lower part is afterwards covered by the plinth, which laps about an inch above the lower edge of the rail. The joints are either all stub-tenons, or, as there is no objection to it, the back tenons are sometimes continued through, as shown.

Framed Work. This consists of rails and posts, or legs, not boxed in, chairs being the commonest example. The parts are united by dowels or tenons, or small members have their ends housed into larger ones, or, in the case of cylindrical parts, the end of a member may be reduced in diameter. Examples of these are shown at A and B in **41**. These are usually held by glue alone, but occasionally fox wedges are inserted. But if the parts fit tightly and are well glued there is little risk of their ever coming apart. An article like **42** is built up by gluing the ends of the columns into holes in the shelves, as in **43**. If the shelves are very thin pieces may be glued to the under-surface as in **44**, to increase the depth of the stud holes, the pieces glued on appearing as part of the column. If it is desired to stiffen the shelves to prevent warping, battens may be screwed across in place of separate blocks, and the stud holes may be bored through these. The stumps of drawers are fitted into blocks, as in **44**. In some cases they are screwed in. Wood drawer knobs are generally screwed into the drawer fronts.

Figure **46** is an example of framed work in which some amount of building up is involved to obtain the required curves. It is the frame of a semicircular washstand intended to be covered with a marble top. The details of its construction are shown in **47**, in which it is turned upside down. The semicircular top on which the marble rests is formed by gluing two layers of segments which are afterwards worked to the sweep on the outside and veneered, the inside being left as it leaves the bandsaw. A bead is formed on the lower edge by nailing on a thin layer of segments with outer edge rounded and projecting. The ends of the sweep are connected by a straight rail notched in flush, and forming the back of the table part. A transverse bar extends from the middle of this to the sweep, being notched flush into the under edge of the latter and covered by the bead segments, and nailed on to the edge of the back rail, the depth of the rail being less than that of the sweep. The main purpose of this transverse bar is to provide an attachment for the top of the pillar, which comes within the curved front. The base is a piece of $\frac{1}{2}$-in. wood lined up to about 2 in., and

34—36. veneered. It does not rest directly on the floor, but on projections extending about an inch below the thickening or lining pieces. The two back uprights are carried through, as shown, to form feet at the back, and one other is formed at the front by a pad, which is nailed on. The pillar is slipped in after the parts are together, and nailed from above and below.

Brackets, either of metal or wood, are often used to strengthen joints. A wood bracket is shown in **48**. These are roughly sawn, but the angle of the back must be accurately finished. They are used only in hidden parts, a common instance being the interior angles of chair seats. Where brackets are required in exposed places they must be neatly finished, generally to a more or less fanciful shape, and if of wood, the screws are inserted through the work into the bracket instead of through the bracket, as in **48**.

Chairs. The seats of these, when not of solid wood or turned rings, are usually dowelled or tenoned, and glued, and sometimes strengthened by brackets of wood or metal screwed into the interior angles. The back and back legs are in most cases continuous, and the seat notched into them and screwed or nailed. The front legs are glued into bored holes. Rails connecting the legs are glued in similarly. Cross-pieces in the back are tenoned, or dowelled, and glued. Very often some of the parts are of bent wood. Special appliances are employed for making these. It is done by steaming the wood and clamping it in an iron mould, the mould itself often being formed with a chamber and pipe for steam heating its surfaces.

Tables. The methods of framing the legs and rails and buttoning on the tops of plain tables has been described in Joinery. Small tables, such as **49**, do not require such elaborate methods. The top would not be buttoned but screwed on through the rails, or if very narrow, glue blocks might be used. The rails might be housed or tenoned into the legs, but in most cases would be dowelled. The bottom rails, to which the tray or shelf is attached, might be housed into the legs, as in **50**, and the tray notched to fit the legs. The rails then would be glued in and nailed through the inner faces of the legs, where the nails would not show, though in many similar cases there is no objection to putting fine nails through from the outside if required. In some cases the tray might be attached to the under edges of the rails instead of on top, and then would be nailed to them. Figure **51** is a heavy writing-table, which does not differ greatly in constructive details from plain tables described in Joinery. Its frame is arranged to receive two drawers in the side instead of one in the end. Its top is built as in **26**, but covered with leather bordered by veneer. Its turned legs, with castors, are a detail which does not affect the construction of the table. A general view of the frame with top removed is shown in **52**. The lower bearer is tenoned into the legs while the upper one and the end and back rails are dovetailed into them. Drawers are constructed as in **53**. In cheap work the backs are nailed instead of dovetailed.

Extension Tables. The commonest form of extending table is shown in **54**. In this there are double rails secured to the legs at opposite ends, and, when closed, the free ends of each pair of rails fit loosely into housings in the legs. They are also tied laterally by stretchers. The rails are kept in alignment by tongues and grooves, usually dovetailed, as in **55**. Large tables of this class have three sets of rails, the middle ones being supported by the others or by extra legs. The frame is usually extended and closed by a screw worked by a key, and a separate leaf fills the space left when the ordinary top is opened. Another form of table with a folding top is shown in **56**. In this the top is pivoted, so that when unfolded it can be swung round at right angles to its position when closed, the long way of the frame then affording sufficient support for both flaps. When square legs of tables or other articles are tapered, as in this example, all the taper is cut from the inner faces.

Flap Tables. Ordinary flap tables have their flaps supported by brackets, swinging legs, or slides which draw out from the frame. Figure **57** shows methods of attaching brackets to the rail of a frame. The simplest is to hinge them, as at A, but for appearance the joints at B and C are preferred, C being considered the neatest; B is known as a finger joint, and C as a knuckle joint. Another way is to pivot a piece in the top of the rail, as at D, which can be swung out to support the flap. The point in favour of this is that it lies flush with the rail when closed. Swinging legs are hinged, as in **58**, sometimes with a tie near the bottom as dotted. The rule joint [**59**] is the usual method of hinging flaps.

Articles with more than three legs sometimes require levelling to prevent them from rocking, due generally to inaccuracy in the superstructure. The exact amount to cut off may be marked as in **60**, by standing the article with three of its legs on blocks of equal thickness on a true surface, and setting a fourth block against the fourth leg, which should be the one which requires cutting. The top surface of this block represents the correct length to cut the leg to. Another way is to mark from the floor with dividers instead of getting the depth from a fourth block.

Writing-tables and Desks. These are generally of the pedestal type, with a kneehole between. A table in which the top and pedestals are in separate parts is shown in **61**. The construction of a pedestal has already been illustrated in **31**; **62** shows how the top is framed. The grain of the ends runs horizontally, but in this example the table is veneered and the grain of the veneer on the upper part is made to correspond with that of the pedestals.

More frequently pedestal tables are made in one framework. Figure **63** is the carcase of a cylinder fall-desk. The sides are shown plain, but in many cases would be panelled. The table generally fits in grooves in the ends and is made to draw out several inches beyond the front. Figure **64** is an end view of the fall. It is pivoted at the centre from which its curve is struck, the connecting pieces generally being of hoop-iron. It is staved up on a block as in **65**, and the staves should be dowelled or tongued as well as glued. The back of table and back of fall are usually connected, so that the fall opens when the table is drawn out and closes when it is pushed in. Figure **66** is another form of roll-top desk with a flexible fall. This is an improvement on the cylinder fall, and is now in more common use. In this the fall slides in grooves in the ends. It is formed by gluing strips of wood on canvas, as in **67**. The pedestals are panelled and connected by a panelled back and by a stretcher in front secured by metal angle brackets. The drawers lock automatically by means of catches which clip their backs. These catches are released by pressure of the fall when it is pushed back as far as it will go. The lock on the fall is of a kind which locks itself when the fall is drawn down, and requires a key only for unlocking. These desks are usually made of oak. The table is solid board screwed directly on the pedestals. A writing bureau is

shown in 68. The cover is hinged, and when opened is supported by two slides which draw out from the carcase. On writing-tables with level tops loose desk slopes are often used. These are very simple in construction, sometimes consisting only of a piece of board tilted by two tapered battens screwed to its under surface.

Bookcases. Sometimes these consist merely of an open carcase with shelves, but to keep dust from the books the best cases are fitted with glass doors. A common type of bookcase is shown in 69. In this the upper doors are glazed and the lower ones wood panelled, as there would be some risk of glass getting broken in the latter. The parts are made separate, as in 70, and the lower part is wide enough to project 4 in. or 5 in. in front of the upper, thus providing a useful ledge and being better proportioned for the larger books it is intended to contain. The upper part should have a vertical partition in the middle behind the meeting stiles of the doors. If the length of the shelves exceeds 4 ft. the lower part would be better with a similar partition. The upper part is lap dovetailed at the corners, and the partition housed in and screwed. The lower part has two stretchers lap dovetailed in at the top, and its bottom may be housed and nailed if covered by plinth, or fitted into a dovetail groove and glued, and in either case may be further strengthened by glue blocks in the angle beneath. The front edges of the sides may have pieces glued on to form pilasters, thus giving the sides an appearance of greater thickness than is actually the case. A top is screwed on to the stretchers of the lower part, and the upper part is screwed on to this. The doors of the upper part are hinged on the face of the frame.

Shelves are generally made adjustable in height. A common method of doing this is to screw saw-toothed strips about $\frac{3}{8}$ in. thick against the sides, as in 71. Bearers of similar thickness are made to fit between, and on these the shelf ends rest, the ends being notched at each corner to clear the saw-tooth strips. The alternative to this method is to have two columns of holes corresponding with the saw-teeth in the last example, and to insert pins in these to support the shelves. These pins are of metal, and there are several varieties of them.

Sectional bookcases have become very popular and are best where the number of books is constantly increasing. Bookcases like 69 look well as an article of furniture, but they are suitable only for a fixed quantity of books. Sectional cases consist of a number of separate boxes each with a capacity, say, for twenty average books. These sections are all alike and provided with simple means of uniting them end to end or one on top of another. A glass door may be fitted to the front of each section. A convenient arrangement is to hinge the doors at the top, and make them so that when lifted into the horizontal position they can be slid back into the case, leaving the front clear and the books uncovered.

Wardrobes and Cabinets. Wardrobes are a common example of large carcase work. They are usually made in three parts, the plinth and cornice being separate from the body, and these parts fitting together loosely with blocks or dowels as guides, and in some instances screwed together. Figure 72 is an illustration of an ordinary plain wardrobe. It has a drawer at the bottom, and the door in the middle is panelled with a mirror. The sides are lap dovetailed to the top and bottom similarly to the bookcase in 70. In the best work, backs are panelled, but generally matchboarding, ply board, or a number of panels between muntins, as in 36, are put in the back. As the doors of wardrobes do not extend across the entire front, pieces, either panelled or plain, must be put on. In many cases these are nailed or screwed directly on and the holes plugged. Where this is objectionable they are glued and dowe led, or screwed from the inside, and sometimes glue-blocked. Figure 73 shows a joint between front and side. With a drawer at the bottom, as in 72, the parts of a large wardrobe would generally be jointed at the bead above the drawer, and the plinth would generally be solid with the lower part, as in the bookcase [69]. The methods of constructing more complex wardrobes do not differ much from what has already been described. Doors, whether in the middle or at the sides, close against the front edges of the frame, as in 74, which is an example of a door hinged to a side. Drawers in the lower part generally work between pilasters formed as in 70, guides of course being required flush with the pilasters, and the width of the latter representing a corresponding reduction in drawer width, the space behind the pilasters not being utilised. Beads are often formed as in 73, where joints occur on the outer faces of front and sides.

Figure 75 is a cabinet with glass doors, and drawers and table above. Its carcase is framed with bottom, shelf, bearer and runners for drawers, and stretchers dovetailed in at top to screw the table on to, none of which differs essentially from what has already been described. The back portion, which forms the main support of the upper shelf, is panelled and screwed on behind. Figure 76 is another form of cabinet, veneered, inlaid, and decorated with ormolu. It has three doors, the middle one containing a mirror, and the two side ones being curved, with glass panels. The curved rails of these doors might be of solid wood worked to the sweep and veneered, but the best way is to form them of a number of layers of veneer bent round a block and glued together. The base and top may be built up as in 77, and the four uprights which enclose the doors may be halved in flush with the outside faces, and the outstanding blocks put on after.

Glass in Furniture. The ordinary methods of inserting glass are shown in 78 to 80. In 78 the glass drops into rebates and is secured by wood fillets behind. The method shown in 79 is suitable only for mirrors. In this the glass goes into a rebate as before, but is protected behind by a backing of flannel and board, the flannel being flush with the back of the frame, and the board screwed on. In 80 the glass fits loosely in the rebate, and is centred and secured by glue blocks as shown. Glass divided by ornamental bars into a number of panes is fitted similarly to that in ordinary windows, except that wood fillets are more generally used than putty. When these have to be bent to curves they are generally of birch or other flexible wood. Where the bars form a very ornamental pattern they are sometimes merely stuck on the surface of a single sheet of glass. Plain and bevelled mirrors may be purchased in great variety of size and shape, or can be obtained to order.

Miscellaneous. Figure 81 is the frame of a couch. The feet are supposed to be dowelled to the under part of the frame. An alternative is to tenon the rails in similarly to those of a table. The upper parts which form the back and end are tenoned or dowelled and glued in the most convenient way to produce the outline desired. Figure 82 shows the

usual method of fitting the feet of circular tables and other articles into the centre post. Screw heads are sometimes concealed by gluing buttons [83] over them. Three methods of forming rounding interior angles in frames are shown in **84** to **86**. Figure **84** is satisfactory, but involves either gluing on a piece or cutting out from one of the members. Figure **85** is a good method when the parts are mitred. Figure **86** has the advantage of allowing the straight pieces to be planed up parallel.

Glue blocks, as illustrated in Joinery, are very commonly used in cabinet work. In many instances, where widths are not great, they are used across the grain. The union of rails to table legs, for instance, is often strengthened in this way. Wire nails are very often used on exteriors without any attempt at concealment, while in other cases they are punched in and the holes stopped, but their presence can, of course, be detected if they are looked for. Metal connections, such as brackets and thin plates or strips, screwed on, will often make a substantial job of what would otherwise be weak owing to slender proportions of wood or a difficulty in making a sufficiently strong joint between parts.

All parts of furniture that are either ornamental or standard in form may be purchased ready made at not much higher prices than the cost of the material. Thus, prepared and carved panels, pediments, brackets, trusses, plain and embossed mouldings and beadings and pressed wood ornaments, can be more economically purchased than made. All kinds of turned work, such as legs, spindles and knobs, are kept in stock by turners and seldom require making to order. There are also so many designs in inlay available that the cabinet-maker never needs to do anything more than select from them. All these articles may be purchased either from specialists or from large firms that stock all of it.

Glass-papering. On a large scale this, and scraping also, are done by machines. Glasspaper is used first to remove tool marks and other slight inequalities and secondly to make surfaces smooth. It is necessary to rub down with glasspaper after the first coats of varnish or stain have dried, to remove the roughness caused by the raised grain. Surfaces, therefore, have to be glasspapered two or three times in the course of finishing the work, and each time paper of finer grade, or paper that has been worn finer by use, is required. A flat surface is done with the glasspaper, kept flat on a rubber as in **87**, and the direction of the rubbing must be with the grain or the surface will appear scratched. Cork rubbers are best, but often a block of wood is used instead. Rounding surfaces are done with the hand, as in **88** and **89**. Hollows are generally managed similarly, though in some cases rubbers of the correct shape are made. Quirks and narrow places may be rubbed with paper simply folded, as in **90**, or wrapped on a thin piece of wood or metal.

Staining. This is done to improve the colour of soft and cheap woods and make them resemble more expensive varieties. The resemblance, however, is chiefly in colour, for in most cases the grain shows unmistakably what the wood actually is. In staining, any inequalities in the shade of the natural wood are corrected. Some parts are generally lighter or darker than others, and this looks especially bad when two pieces are glued together, and the joint is made conspicuous by a sudden change of colour. This, of course, is avoided as far as possible in selecting the wood, but it is further corrected by applying an extra quantity of stain to light parts to make the colour uniform. This matching of the colour of parts is done more or less in nearly all polished work, even when the natural colour of the wood is supposed to be showing. Stains are sold in liquid form ready for use, and are applied with a brush. Hard woods may sometimes be improved in appearance by having their natural colour darkened. Wood darkens with age, but is done artificially by oiling, by staining, or, in the case of oak, by fumigating with ammonia.

Polishing. This is the usual method of finishing cabinet work. There are several ways of doing it, but by far the commonest is known as French polishing. In this the polish is simply shellac varnish (which is shellac dissolved in methylated spirit) applied with a rubber instead of a brush. In order that the polish may be permanent it is necessary to ensure its not becoming absorbed into the wood surface and losing its lustre. The pores of the wood, therefore, are filled by rubbing in a filling medium to economise time and material in applying the polish. There are many fillers employed, plaster of Paris and whiting being common ones, made into very thin paste with oil, water, or turpentine. The filler should be coloured to suit the wood. After this has dried and been rubbed down the process of *bodying in* begins.

The rubber with which polishing is done is a pad of cotton-wool damped with polish and wrapped in a piece of soft linen rag, one thickness of linen only covering the wool. The polish is rubbed evenly and quickly with light pressure of the rubber over all parts of the surface to be polished. The movements of the rubber are unimportant as long as all parts are treated equally. As the rubbing proceeds, the polish dries and the pressure then may be slightly increased. A little linseed oil is applied to the linen when it does not move freely over the surface, but too much oil will make it impossible to get a good polish. This bodying in should properly be done three or four times, with intervals of several days between each, otherwise it is likely to sink in and diminish the lustre of the polish. The coat of polish should be as thin as possible, to show up the figure of the wood and avoid the yellow colour of a thick coat of shellac. The bodying in is followed by a concluding process called *spiriting off*. In this a very thin polish and finally methylated spirit alone is used to remove oil, smears, rubber marks, and any inequalities. It is, in fact, polishing the surface of the coat of shellac, and, if carried too far, will dissolve and remove the shellac and so spoil the work. The final rubbing should follow the grain of the wood. The pressure should be light and the rubber kept moving. Intricate parts are difficult to polish, and are generally given four or five coats of thin varnish with a brush.

The mediums used in other kinds of polishing are chiefly wax and oil. They give comparatively dull results and are used only for special purposes.

CONTINUOUS WAVES & TELEPHONY

THE transmission of signals by Hertzian waves naturally led to attempts to transmit speech by wireless, but speech had already been transmitted without the use of wires for many years by means of light.

The Principle of Wireless Telephony. Light, it has been already observed, travels at the same speed as wireless signals, namely, 185,000 miles per second; and both light and Hertzian waves are due to electromagnetic oscillations in the ether, one of their chief differences being in wavelength. If a telephone mouthpiece or microphone be attached to the tube conveying gas to a special type of burner, the words spoken into the microphone will cause vibrations in its diaphragm which will influence the gas supply, and the flame of the burner will vary in accordance with the speech, the light of the flame varying proportionately. By concentrating the light of this flame by means of a parabolic reflector, the rays of light will carry several yards, and can be intercepted by another reflector (or lens) and concentrated on a selenium cell. Selenium has the remarkable property of varying in its electrical resistance according to the intensity of the light in which it is placed. Consequently, as the beam of light transmitted from the transmitting apparatus—varying always in accordance with the speech—is collected and concentrated upon the selenium cell, the resistance of the cell varies and regulates the current passing from a local battery through a telephone receiver, and reproduces the original speech.

Damped oscillations, produced by a transformer or induction coil in the manner already described, have only a frequency of some hundreds or a few thousands per second. Speech, on the other hand, is produced by vibrations which may run sometimes into thirty or forty thousand per second; and in order to transmit speech by wireless it is therefore necessary to employ oscillations which have at least as high a frequency.

Production of Continuous Oscillations. Continuous oscillations of a very high frequency are produced in various ways at the present time, chiefly by means of (1) the singing arc, (2) high-frequency alternate-current generators, and (3) particular types of spark apparatus.

In 1900, Mr. Duddell showed how continuous oscillations could be produced by means of special arrangement of arc lamp, condenser, and inductance, which is shown in diagram form in **27**. Here D represents a source of continuous current, such as a dynamo or battery of accumulators; A is the arc lamp, K the capacity, and J the inductance. A high voltage (400 volts upwards) is usually employed, and the inductance must have a low resistance. The number of oscillations produced in this way has been as high as 400,000, while over 130,000 per second have been actually recorded photographically.

The arc lamp, owing to the physical conditions produced by the shunted capacity and inductance, gives rise in reality to a very high number of spark discharges, or their equivalent, and thus to an almost uninterrupted train of waves. There are various ways of making the speech affect these waves, one being shown in **28**. M represents here the microphone, and B a battery. On talking into the microphone, variations in current intensity are produced in the coil, L, acting as the primary of a high-frequency transformer, of which H is the secondary, H being also the inductance coil shunted across the arc. Choking coils, C C, are sometimes used in the leads from the source of direct current to the arc, but are unnecessary if the lamp is fed from a dynamo or accumulators not supplying power elsewhere. The microphone currents have also been used to influence the field magnets of the dynamo supplying current to the arc, and the arc will then repeat words or music spoken or played into the microphone. With an apparatus of this type a musical arc concert was given by Simon in Frankfurt some years ago.

The Poulsen Arc. Poulsen made a considerable advance in the production of high-frequency oscillations by discovering that practically undamped waves could be obtained if the arc flame were formed between a carbon and a cooled metal electrode (or pencil) in an atmosphere of coal-gas or hydrogen The shunt circuit need then have only a very small capacity. A further feature of the Poulsen arc is that two magnets are placed so as to form a magnetic field across the arc, as shown in **29**. C is the carbon electrode, which is kept slowly rotating, and M is the metal electrode, which is water-cooled by means of water circulating inside. N and S are the poles of a powerful electromagnet, and B is the battery of accumulators or dynamo. J_1, the inductance in the shunt, acts as the primary of the oscillation transformer, J_2 the secondary supplying the energy to the aerial in the usual way. A fairly large inductance, about one-tenth of a millihenry, is employed, and powerful oscillations are produced, giving an almost continuous train of waves

These oscillations can be used, of course, for telegraphy as well as telephony, and the Poulsen system of telegraphy is in actual operation between San Francisco and Honolulu, the transmission thus taking place over nearly 2400 miles.

The Poulsen Telephone Transmitter. In the Poulsen transmitter for radiotelephony the microphone is either placed in the shunt circuit of the arc or in a third inductive circuit by itself —a method also adopted by Grindell-Matthews. The effect of the speech is to alter the resistance of the shunt circuit, which appears to affect the shape of the ether waves, distorting them, as it were, or altering their amplitude, and so rendering them capable of giving up, at the receiving station, waves the distortion of which can be reconverted or reconstituted into speech. A form of detector capable of being affected by variations in amplitude must be employed at the receiving stations, and an electrolytic, vacuum valve, or special form of crystal detector is usually used.

The chief difficulty in the transmission of speech is the small amount of current which can be

passed through any ordinary form of microphone. In order suitably to modify the oscillations, fairly powerful currents are necessary if the speech is to be transmitted over any distance, and the carbon microphone used for line telephony becomes unavailable.

Here we find the solution in a fine achievement of the Italian scientist Majorana, whose *acidulated-water microphone* enables currents of very considerable intensity to be brought into play. The mouthpiece of the microphone is attached to a diaphragm which vibrates in accordance with the speech, and to the diaphragm is attached (rigidly) a small tube through which acidulated water is flowing. The stream of water falls upon two rings of metal, one inside the other, and separated from each other by some insulating material. As the water is acidulated, and therefore a conductor of electricity, the film of liquid, falling on the rings, connects them electrically, and current can pass from one to the other. The effect of speech is to vibrate the diaphragm, which, in turn, vibrates the jet of water, and varies the frequency of the drops, thus altering the thickness of the layer or film of water connecting the two rings. As the resistance of the water varies with its thickness, the movements of the diaphragm have the effect of varying the current passing between the two rings; and these variations of current, which can be rendered fairly intense, are made to influence the inductance in the transmitter.

Another similar device, due to the late Professor E. Ruhmer, is shown in 30. M represents the microphone mouthpiece, and A B the diaphragm (of mica). T is a glass tube attached rigidly to the diaphragm, supplied with acidulated water from a glass vessel (not shown). The tube, T, terminates in a fine jet, and a thin stream of liquid flows into a vessel, V, provided with an electrode, E. When one speaks into the mouthpiece, the diaphragm, A B, causes the tube, T, to vibrate, and the stream of liquid is thrown more or less away from the electrode, so altering the resistance of the water in V between the end of the stream and the electrode, E. The current which influences the wireless circuit passes from an electrode in the tank through the liquid in T, through the vessel, V, and out from the terminal, X, of the other electrode. This circuit is often placed between the aerial inductance and the earth, and the variations in its resistance vary the intensity of the electric oscillations and the amplitude of the waves radiated.

High-frequency Alternators. Besides the singing-arc method of producing continuous oscillations, we must consider the *high-frequency alternator*, which is a special type of dynamo generating alternating currents of very small periodicity. The condenser circuit used across a spark-gap fulfils its purpose by means of the alternate discharges and charges which take place, creating a number of rapid impulses. The same thing is attained by means of an alternate-current dynamo, provided it has a sufficient number of windings on the armature, and a sufficient number of pole pieces, and is driven at a sufficiently high speed. The number of complete cycles per second in an alternator depends on the number of pairs of magnet poles in the rotor and the rate of revolution. In the case of the Alexanderson alternator, a steel disc with about 400 teeth on the periphery was rotated between the poles of stationary magnets. The teeth, in travelling, diverted the magnetic flux of the magnets upon armature coils, from which currents of as high as 100,000 alternations per second were obtained.

An inductor type of machine [see page 1285] was made at the Central Technical College with 204 teeth on the rotor, which gave 120,000 alternations per second, and both Mr. Duddell and Professor Ruhmer have made similarly successful inductor type generators.

The Goldschmidt System. The most successful type of high-frequency machine, so far, is that invented by Goldschmidt, with which signals have been already transmitted some 4000 miles from Germany to Canada; and it is claimed for it that it is eminently suitable, under certain conditions, for the transmission of speech. The stator coil is excited from a direct-current dynamo, which thus creates around the coil a magnetic field, and the current induced in the rotor coil produces thus an alternating magnetic field around the rotor coil. This moving field produces in the stator a current of twice the original frequency, and in this manner the frequency is multiplied until suitable for exciting the antenna. A practical difficulty is the necessity for driving the alternator at an absolutely uniform rate, but Goldschmidt seems successfully to have overcome this and many other previous difficulties associated with this type of generator.

The Galletti System. There have been various attempts to produce high-frequency currents of great magnitude, suitable for long-distance transmission, by means devoid of moving parts. One notable instance is the Galletti system, by which method, from an immensely powerful station recently erected in France, signals have been transmitted across the Atlantic. In the Galletti generator a cycle of oscillations is produced, one after the other, with such rapidity that the beginning of the second train just joins on, as it were, to the end of the first train, and so on. High tension direct current of about 48,000 volts is employed from a series of special generators, and a large number of spark-gaps of the disc pattern are made to discharge one after the other. The original arrangement is shown in 31, but this has recently undergone some modification.

High-tension direct current from the dynamos, D, is led through resistances, R, to a series of spark-gaps, S, and these gaps produce a series of sparks, 10,000 per second or more, in regular rotation, over and over again. The high-frequency oscillations are formed in the coil, J_1, which acts as the primary of the oscillation transformer. The spark-gaps consist of a series of flat metal discs, separated by thin sheets of mica, enclosed in an air-exhausted chamber and clamped together under very great pressure.

A remarkable feature of the system is the key for switching on the current in an auxiliary circuit, in order to make the signals. This key is merely a water-jet, which can be interrupted with such great rapidity that automatic Wheatstone transmission can be carried on at high speed.

It is interesting to note that the difficulty of hearing persistent oscillations at the receiving station is overcome by forming the oscillations into groups, the group frequency being such that it is readily audible as a musical note.

Hoegerstaedt's System. Another recent system in which there are no moving parts is that of Hoegerstaedt, who places a series of coils in a rotating magnetic field [see page 1684]. As the magnetic field sweeps through the series of coils, it induces alternating currents in each one in succession; and as all the currents in *one* direction are further neutralised by means of a permanent

magnetic field, which adds to the currents in the other direction, the inventor claims, like Galletti, to produce a persistent series of uni-directional currents.

The Trend of Wireless Development. The trend of modern work is to produce persistent, undamped oscillations, as they are apparently unaffected by daylight, carry much farther for the same expenditure of power, and are far more difficult to "tap," tuning at the receiving station having to be most accurately carried out, and very perfect syntony resulting. It is highly probable that in the near future automatic transmission and automatic printed slip reception at a speed of some 200 words per minute will represent the commercial form of radiotelegraphy, with continuous oscillations. Captain Hovland, of the Norwegian Navy, has already made (and demonstrated over some considerable distance) an automatic *wireless typewriter*, with which the messages, as received, are actually printed in type. The system is capable of making use of one of several thousand different codes, so that for secret purposes it would be practically impossible to intercept an intelligible message.

The Transmission of Photographs and Drawings. Another interesting possibility is the transmission of photographs and drawings by wireless. The writer recently showed at the Royal Institution an apparatus that had been specially designed for this work.

Fig. 32 shows the transmitting device. C is a metal cylinder on which is wrapped a tinfoil sheet on which the sketch has been drawn in insulating ink. A metal stylus, T, presses on the cylinder, which is revolved with a motion similar to that of a phonograph, so that T gradually traverses in a spiral line the whole surface of the sketch. Every time the stylus comes over one of the insulating lines of the sketch, contact is broken, and the current passing from a battery, B, through the stylus and cylinder and the magnet, M, is broken. These interruptions cause interruptions at the contact, P, which acts as a Morse key for the induction coil or transformer, I, and thus the aerial, A, radiates signals in accordance with the lines of the sketch.

Fig. 33 shows the receiving apparatus. Here the signals, as "picked up," after rectification through a suitable detector, D, are passed through a fine silvered quartz fibre, W, the moving part of an Einthoven galvanometer [see page 5898]. This fibre, although only 1–12,000th inch in diameter, suffices to act as a shutter to cut off the rays of the Nernst lamp, A, which otherwise fall on a photographic film attached to the cylinder, C. This cylinder is enclosed in a light-tight box, and is rotated with the same spiral motion as the cylinder of the transmitting apparatus, and at precisely the same speed. Each signal, as received, causes the fibre, W, to shift, and so allow a spot of light (concentrated by the lens, L, shown) to act on the sensitive film. When, therefore, the transmission is complete and the film developed, a replica of the original sketch or photograph is obtained.

Both Professor Korn (the inventor of the telautograph) and the writer have transmitted pictures by wireless over short, experimental distances. When such a system is developed, it may be possible for photographs of criminals to be sent by wireless to big ocean liners on which they may be escaping from justice, or for photographs to be included in the wireless newspapers which now form a regular, everyday feature of ocean travel.

International Time-signals. The big station at the Eiffel Tower transmits daily time-signals of two kinds—ordinary time-signals sent out twice daily, at 10 a.m. and midnight, and, just previously, accurate signals by which scientific calibration of clocks can be effected. Meteorological telegrams are also transmitted at 10 a.m. and 5 p.m., special notices to navigators, and also what are termed "measure signals" for studying the variations of intensity of signals, and so on.

The ordinary time-signals are preceded, five minutes before ten, by a call signal, —.—.— three times, and then the "wait" signal, .—... The control of the actual signals is carried out at the Paris Observatory.

The scientific time-signals begin at 11.45 p.m., as a series of 300 dots, each one due to a single spark, and the 60th, 120th, 180th, and 290th are suppressed in order to facilitate counting. The method of correction by means of the signals is fully explained in an interesting article in the "Year-Book of Wireless Telegraphy and Telephony (1915)."

Wireless in Meteorology. The barometric situation in Europe, and the state of the weather as indicated by fourteen European observatories, are transmitted each day at a quarter to eleven, this report being preceded by the initial letters B C M (Bureau Central Météorologique). A code is employed in order to facilitate the condensing of the messages into brief despatches, and the full code and method of decoding the radiotelegrams will be found fully dealt with in the article mentioned above

The German station at Norddreich also sends, twice daily, time signals, at noon and midnight The wave-length employed is 1650 metres. Similar time or meteorological signals are also sent daily from Scheveningen (Holland), Carabanchel (Spain), and from various stations in the United States, Japan, Australia, South Africa, Mexico, and, lastly, from Whitehall and Cleethorpes in this country.

Amateurs will find it necessary, owing to the somewhat long wave-lengths usually employed for these signals and bulletins, to employ large inductance coils in order to receive really good signals, but these may be readily made by winding enamelled copper wire of about No. 20 or No. 22 gauge on an ebonite or well-insulated cylinder $2\frac{1}{2}$ in or more in diameter.

The inductance can be calculated in absolute units from the formula

$$L = 4\,\pi^2\,n^2\left(\frac{2\,a^4 + a^2\,l^2}{\sqrt{4\,a^2 - l^2}} - \frac{8\,a^3}{3\,\pi}\right)$$

where a is the mean radius of the coil, n the number of turns, and l the length in centimetres.

Applications of Wireless Telegraphy. Apart from the transmission of speech, messages, and pictures, almost every year new applications of wireless are being found, and, of course, many romantic claims made, which on investigation are found to be baseless.

One of the schemes most fascinating to the more imaginative type of inventor is the transmission of power by wireless. Perhaps the day may come eventually when a locomotive may be able to pick up its power by wireless from a generating station at the terminus of the railroad. At present all attempts in this direction have been futile; but the control of ships at sea from some point on the land, the firing of mines, the firing of isolated fog-guns, and so on, are already things of reality.

Motor lifeboats have already been fitted with wireless, in order that they may proceed some short distance ahead of the parent ship in foggy weather,

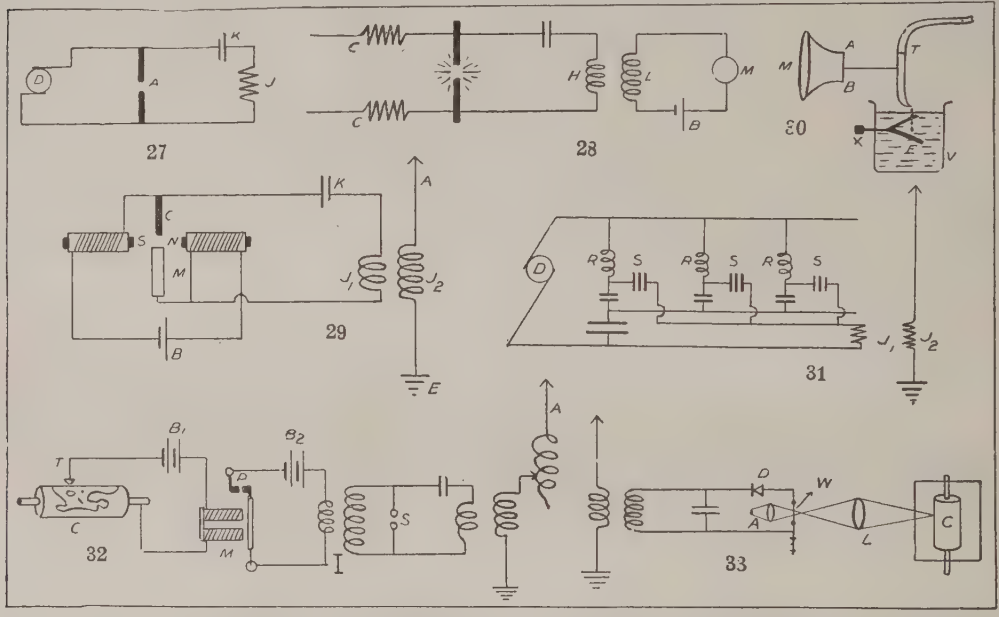
and signal to the latter the presence of icebergs. Similarly, in the whaling industry, two or three small steamers fitted with wireless usually work in conjunction with the large steamer. That a lifeboat equipped with wireless, besides being able to communicate with its parent ship, could also detect icebergs by a wireless apparatus is within the bounds of practicability.

Already wireless "explorers" are in existence for the location and tracing out of pipes in the ground, and, by means of an ingenious invention of Mr. A. W. Sharman, the position of gas-pipes underground can be traced out and distinguished from the position of water-pipes or electric mains. The Sharman *locator* consists of two parts—the generator and the indicator. The generator is a device emitting a peculiar type of electrical impulses, and the indicator consists of a framework of insulated wires. When the generator is attached to some part of a pipe which is to be traced out, one terminal of the high-frequency generator being connected with the pipe, the other with a metal spike stuck in the ground near-by, the electric impulses spread through the surrounding network of pipes, and give rise to ether waves which are readily detected by the indicator. The coil on the indicator is connected to the terminals of a double headpiece telephone; and as the indicator is held a few feet above the ground in different positions, sounds are heard in the telephone which are of maximum intensity in the immediate neighbourhood of the underground pipes. By tracing out the "line" of maximum intensity, a pipe can be located, and its depth below the ground determined with considerable accuracy. The instrument is seen in use on page 6012.

Wireless Control on Railways. Wireless fog-signalling is another new branch of radiotelegraphy which deserves mention. By it it is possible in foggy weather to control the movements of a train from a central station, the apparatus on trains in one direction being adjusted to one impulse frequency, that on trains moving in the opposite direction to another frequency, so that trains meeting would stop at a safe distance apart.

Some interesting and highly successful experiments were recently carried out at Nürnberg, in which the brakes were applied from a wireless cabin to trains travelling at forty miles an hour, and the train brought to a standstill at any desired spot. Wireless control of this type would save immense outlay in the construction of long railway lines.

Atmospherics and Atmospheric Absorption. The energy of electric waves is gradually absorbed by the atmosphere, short waves usually suffering in a greater degree than long waves. Marconi observed in 1902 that signals that carried 1500 or more miles at night-time would only carry for about 700 miles in the day. The action of daylight is responsible for the greater absorption; sunlight produces partial ionisation of the atmosphere, and renders it conductive, whereas electric waves suffer the least absorption when travelling through a non-conductive medium like the ether.



DIAGRAMS OF SYSTEMS AND APPLICATIONS OF WIRELESS

27. The singing arc **28.** Microphone acting on singing arc **29.** Poulsen arc **30.** Ruhmer's microphone **31.** Original arrangement of Galletti system **32.** Thorne Baker photographic transmitter **33.** Receiving apparatus for photographs

One of the greatest difficulties in long-distance transmissions is the natural electrical discharges of the atmosphere, and many investigations are being carried on, to be later co-ordinated and sifted out, in order to come to some more definite conclusions regarding both atmospheric absorption and atmospheric discharges.

An *atmospheric* is picked up by the antenna of a wireless station and is heard as a soft hiss or buzz in the telephone, which might be interpreted as a dot or dash according to its length. The old coherers originally used with the Morse inker sets would, of course, always respond to these discharges, which would often obliterate or render quite unintelligible the messages received. Atmospheric disturbances are always more pronounced in tropical countries. Many devices have recently been tested for "filtering out" atmospherics from the legitimate Morse signals.

Various interesting points arise in the matter of ordinary atmospheric absorption For example, in working across the Atlantic, it will perhaps be daylight at Clifden and night at Glace Bay (the Nova Scotia station). Mr. Marconi has found that the weakest signals are transmitted when the boundary between day and night is about halfway between the two Transatlantic stations. There is also a marked difference between the effects of atmospheric absorption when transmitting from north to south and from east to west.

T. Thorne Baker

THE WIRELESS OPERATOR

If not a road to great wealth, a career as a wireless operator is one which presents distinct possibilities, ever increasing with the steady growth of radiotelegraphic services, to the young man of mechanical and scientific bent who has a desire to see the world. It is one of the very few careers which necessitate no lengthy and costly training, and which, once the necessary training is completed, practically assure the candidate, without any weary waiting for an opening and without the call for a heavy premium, an entry into the salary-earning arena, where he is at once independent.

The demand for wireless telegraphists exceeds the supply of competent men: and although the end of the European war will set free a large number of operators to fill posts in the mercantile marine, the "safety of lives at sea" regulations, which come into force in 1916, will make it compulsory for every ship carrying fifty or more persons to maintain a complete wireless equipment. Each ship will require one and, where constant watch is kept, two operators to maintain service. Moreover, the number of land stations now in course of erection will each call for a staff of men.

Physical and Educational Standards. The man who contemplates a career in the wireless service must be in sound bodily health, and his hearing must be perfect. Before beginning his training he should be examined by a doctor, to be assured that all is right in these respects.

The educational standard requires a good general knowledge, the ability to read, to do elementary arithmetic, and to write clearly. Stress is laid on legible handwriting, because the operator has to write out messages without error, and without possibility of misconstruction, as he receives them. A knowledge of electricity and magnetism, of foreign languages, or of telegraphic work is not essential, but all in favour of the man who possesses it. With these qualifications the candidate is fit to enter on his training as a wireless operator, the aim of which is to secure the Postmaster-General's first-class certificate of proficiency in wireless telegraphy. There is no age limit in this examination, but, preferably, wireless operators should take their certificate between the ages of eighteen and twenty-five.

The Postmaster-General's Certificates. Under Article 10 of the regulations annexed to the International Radiotelegraph Convention, every person operating wireless telegraph apparatus on board ships registered in the United Kingdom must hold a first or second class certificate of proficiency from the Postmaster-General. This is awarded, after examination, only to British subjects.

The *first-class certificate* is granted only to fully qualified operators whose speed of working is not less than twenty words a minute. The *second-class certificate* is granted to operators whose general qualifications are satisfactory, but whose working speed is only from twelve to nineteen words a minute. Operators holding the second-class certificate are only allowed to take charge of the apparatus on ships, such as fishing-vessels, which use wireless for their own service, or as substitutes on ships which have on board at least one first-class operator. It will be clear, then, that unless the candidate is to be content with a very humble position in the new profession, he must secure the first-class certificate, for without it he can never be in charge of an important installation. The Marconi service is only open to men with first-class certificates.

The Examination. Candidates for the certificate will be required: (*a*) to send on an ordinary Morse key for five consecutive minutes at not less than the prescribed speed—the accuracy of signalling, the correct formation of letters, and the correctness of spacing will be taken into account; (*b*) to receive and write legibly at the prescribed speed from a double headgear telephone as ordinarily used for radiotelegraphic reception; (*c*) to understand simple diagrams of the electrical connections of the apparatus used in the system in which he is being examined; (*d*) to be able to connect up the apparatus with the help of such diagrams, so far as this is required in the system in which he is being examined; (*e*) to name the principal parts of the apparatus and indicate their use; (*f*) to mention the most common faults and the means usually taken to remedy them in the system in which he is being examined; (*g*) to explain the steps taken to change from one wave-length to another, in sending and receiving, in the system in which he is being examined.

The examination also embraces a practical test in: (*a*) connecting up apparatus; (*b*) operating (sending and receiving); (*c*) regulating and adjusting; (*d*) altering the wave-length; (*e*) reducing and increasing the transmitting power; (*f*) tracing faults.

Notes on the Examination. Candidates for examination must fill up and return to the Secretary, the G.P.O., London, a form of application which will be found in the "Handbook for Wireless Telegraph Operators" (to be purchased, price threepence, from Messrs. Wyman & Sons, 29, Breams Buildings, Fetter Lane, London, E.C.), from which the above regulations are taken. The fee is five shillings. The date and place of examination will be notified to the candidate. Examinations are generally conducted at the General Post Office, London, but may be held at wireless schools throughout the country if they possess suitable apparatus for the purpose. The candidate may be examined in any well-known system of radiotelegraphy, and his certificate will indicate the system or systems in which he is proficient. It may be remarked that, in this country, the Marconi service holds by far the greatest opportunities. Once the operator has mastered this system, he should have little difficulty in understanding any other with which he may come in contact. On passing the examination a candidate is required to make a declaration that he will preserve secrecy regarding all radiotelegraphic correspondence with which he may deal.

If a candidate fails in his examination he will not ordinarily be re-examined until after a lapse of three months. The holder of a certificate may have it endorsed or suspended if he be proved, to the satisfaction of the Postmaster-General, wilfully or negligently to have failed to comply with the

provisions of the International Radiotelegraph Convention and Regulations.

The sending and receiving test is conducted in the International Morse Code, five letters being counted as one word. The examination with regard to the actual regulations regarding the transmission of messages is based upon the rules contained in the "Handbook for Wireless Telegraph Operators" above mentioned, which contains the International Morse Code signals. Special importance is attached to the practical examination, for the wireless operator is in sole charge of his station, and in the event of a breakdown will have to do his own repairs, unlike the land telegraph operator, who has linesmen and engineers whom he can call to his aid. Each candidate appears alone before the examiner, who creates faults, and makes wrong connections in the transmitting, receiving, and emergency apparatus, the candidate being allowed a reasonable time in which to remedy them.

Facilities for Instruction. Having examined the scope of the examination for the Postmaster-General's certificate and the entrance regulations, we may now consider the facilities offered to the candidate for training. Whatever the system the candidate may choose to make himself proficient in, the groundwork is a thorough knowledge of the principles of electricity and magnetism. This should be familiar to the student who has followed closely the course on ELECTRICITY in the SELF-EDUCATOR A practical grasp of wireless telegraphy is only to be gained at a college or institute of wireless telegraphy where the student can handle the apparatus he will have to use. Moreover, it is essential that the student should have competent instruction in order to acquire a correct "style" of sending. In the International Morse Code a dash is equal to 3 dots, the space between the signals which form the same letter is equal to 1 dot, the space between two letters is equal to 3 dots, and the space between two words is equal to 5 dots; therefore it will be seen that a jerky or uneven style of sending may lead to great confusion, and, if persisted in, will be hard to eradicate.

Among the prominent schools of wireless telegraphy may be mentioned the London Telegraph Training College, 262, Earl's Court Road, London, S.W.; the East London Wireless Telegraph College, 228, Romford Road, Forest Gate; the British School of Wireless Telegraphy, 179, Clapham Road, London, S.W.; the North-Eastern Schools of Wireless Telegraphy, 18, Eldon Square, Newcastle-on-Tyne, 11, Church Street, West Hartlepool, and 22, Blenheim Terrace, Leeds; the North British Wireless Schools, 48, George Square, Edinburgh, with branches at 141, Bath Street, Glasgow, and Melville House, 11, Nethergate, Dundee, whose course of tuition is under the supervision of Dr. J. Erskine-Murray; the Northern Wireless Schools, 11, Lower Sackville Street, Dublin, and 47, Market Street, Manchester; the Manchester and Liverpool Wireless Telegraph Training Colleges, 27, Leece Street, Liverpool, and Carlton House, Fallowfield; the Atlantic College, Cahirciveen, co. Kerry; and the Irish School of Telegraphy, 18, Dyke Parade, Cork. The fees of these institutions vary (roughly, from about 10 to 45 guineas), according to whether day, evening, or postal classes are taken, and whether one or more systems are to be studied. Application should be made to the secretary of any institution. The courses, as a rule, are designed to make a student proficient in a year at the most, but a keen man will have little trouble in getting a grip of a system in nine months. Many students, indeed, have gained the P.M.G.'s certificate within a shorter period.

The Marconi Schools. For those who desire to enter their service, the Marconi Wireless Telegraphy Company have schools at Marconi House, Strand, London, W.C., where instruction is given during the day in both the theory and practice of wireless telegraphy, students being taught to operate, adjust, and repair apparatus of the same type as is installed in ship stations. The London school is fitted with ½, 1½, and 5 k.w. stations. A beginner with no previous business experience signs on as a servant of the company, and is paid 5s. weekly while he is undergoing this course; men who have had land line or cable telegraphic experience and can send from 20 to 25 words per minute receive 17s. 6d. per week during this trial period at the London school. After gaining the Postmaster-General's first-class certificate, and passing a qualifying examination by the company's instructor, they are drafted into the service of the company. They are then kept in the school for a short period to learn the company's clerical methods and system of accounts. From time to time as vacancies occur the newly fledged operators are appointed to ships. An operator must be prepared to go on any ship to any part of the world.

It should be observed that the gaining of the Postmaster-General's certificate is no guarantee that the holder will be admitted to the Marconi or any other service. Further, students of wireless schools who, on gaining the certificate, are accepted by the Marconi Company must attend that company's classes of instruction in clerical work and accounts.

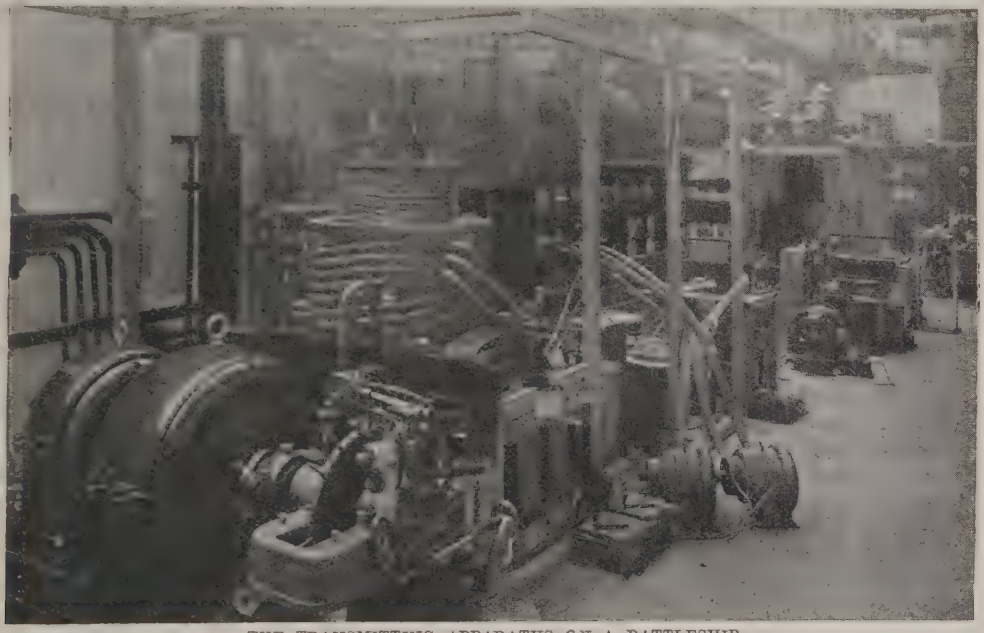
Salaries and Prospects. On being appointed to a ship as junior operator, the Marconi man continues to be an employee of the company, and receives a salary of £1 per week, with all found on board, and an annual increment in salary of 2s. 6d. per week up to a maximum salary of £1 10s. weekly, paid whether or not the ship be laid up in port and he be idle in consequence. His uniform he must buy. On promotion to senior operator, which may come rapidly with efficiency and good conduct, the salary starts at £1 15s. per week, with all found, and rises, with an annual increment of 5s. per week, to a maximum of £2 15s.

On board ship the operator ranks as a junior officer, and he is subject to the same disciplinary regulations as the crew. His work is confined solely to his telegraphic duties, except in special circumstances. Where he is in sole charge his hours may sometimes be long and irregular, but where two operators are employed, as in future will be largely the case, his duties will not be onerous. In his spare time a certain liberty is allowed him to take part in the pleasant social life on board. In the course of his duties his transferences may be rapid, from cargo-boat to liner, and to him, perhaps rather mortifying, from crack liner to some much humbler vessel. There is little cause for mortification, however. The operator of a crack Transatlantic liner has little chance to see the world; he has hardly reached port and got his accounts adjusted before he must be out and on the highway again. On the cargo-boat he will have much more spare time in port during loading operations, his salary being paid all the time.

Promotion. Subsequent promotions are made as vacancies occur, generally according to seniority. After a term at sea an operator may qualify for a

position as travelling inspector, whose function it is to make reports on operators and instruments to the head office of the company he may serve. Inspectorships bring additional pay, which sometimes exceeds £2 10s. per week. For a few men there are posts as resident inspectors, at a slightly higher salary. These officers are stationed at a port, and on them is the responsibility for seeing that the wireless installations of all ships using their system which call at the port are thoroughly overhauled and adjusted. Land station vacancies are reserved, as a rule, for picked men. Senior officers in such a position receive a salary of £250 per annum. The stations are often situated in very remote spots, and may not appeal to the operator who likes the constant change of scene that ship-life brings. Besides these, there are many branches in the company's service where a good man can be usefully employed.

One of the "plums" of the wireless service that may come in the way of a smart young operator is an appointment on board a private yacht. In such a case the pay is usually good, the company agreeable, and the work not too onerous.



THE TRANSMITTING APPARATUS ON A BATTLESHIP

The Wireless Engineer. The erection and maintenance in all parts of the world of stations, both small and large, calls for a special staff of wireless engineers, men with a sound knowledge of mechanical, electrical, and civil engineering, whose work is largely carried out abroad, and who must therefore be prepared to go at any time to any part of the world.

The task may be the erection of a small ship station or of a high-power station in some remote spot where roads may have to be made and buildings set up before the gigantic masts can be assembled and erected, the electrical gear housed, and the service got in working order. Among the qualifications demanded of applicants for posts on the Marconi engineering staff are (1) a good general education up to the age of 16; (2) a suitable general engineering education at an approved technical college or university for not less than two years, with the corresponding certificate, diploma, or degree; *and* (3) not less than two years' practical experience in a mechanical engineering workshop or other suitable place.

"With regard to the nature of the practical work," says the Marconi official publication, "the most suitable experience would include fitting, turning, forging, assembling, and outside installation of engines, including foundations and the lining up of bearings. Also, if possible, experience in the maintenance of steam plant. Experience as a switchboard or sub-station attendant is not of much use. Experience in large electrical manufacturing works is usually distinctly less useful than experience in moderate-sized mechanical engineering workshops, though there are exceptions to this rule."

Engineers of the Marconi Company, before being in charge of a contract, whether large or small, must have some experience of the engagement and control of labour, the transport of goods, including Customs arrangements, and have a working knowledge of accounts and correspondence.

The average age at which men are engaged is from 21 to 25, and occasionally applications are considered from men who have not exactly fulfilled the requirements quoted above.

An applicant who, after an interview, is considered satisfactory is given a probationary period of three months on the engineering staff, with an allowance to cover cost of living during that period, in which he is instructed in the principles of wireless telegraphy and their application. On the nature of the probation report depends whether he is put upon the engineering staff of the company. If he is accepted, his initial salary will depend on previous training and experience.

Making a Pianoforte. Case, Soundboard, and Strings.
How to Tune a Piano. The Building of an Organ.

PIANO AND ORGAN BUILDING

THE PIANOFORTE

One thing is bound to strike everyone who first makes an acquaintance with the manufacture of pianos—namely, the extraordinarily small amount of skilled labour requisite for their production. True, when once the piano has been put together, the greatest skill and the utmost refinement are necessary for the proper regulation and tuning of the finished instrument; but, prior to that stage being reached, only at one or two points in its progress does the piano in the making call for the exercise of great skill and experience. We speak of the daily work in the factory; the designing and calculating of improvements is quite another matter, and calls forth the powers of the engineer, musician, and draughtsman.

The most important material in the instrument is the wood. Not only does good wood give a pleasing appearance to the instrument, but it has an influence not to be underrated on the tone. The hard, close-grained woods are especially esteemed for their vibrating power. English oak, New Zealand kauri, spruce, beech, black walnut, mahogany, and American poplar are among those in common use. Seasoning is carried out with much care; and not until they have been seasoned from three to five, and in the case of woods for high-class pianos even eight, years are they brought into use. Then, having been exposed to all weathers during this long period, the sap is thoroughly amalgamated with the wood; so that, as one writer says: "When the musical wire of the piano is struck, the dried and resinous sap, broken up into infinitesimal particles, acts like so many tiny notes that sing among the fibres of the wood and help to give tone to the instrument."

Making the Case. For purposes of convenience, let us divide the piano itself into three distinct parts. First, there is the case; then we have the soundboard, with its frame and strings attached to it, and lastly we have the action, or mechanism, which transmits the blow from the finger to the string.

Case-making is a branch of high-class cabinet-making, pure and simple. Certainly, the maker has to understand the conditions to which the cases are to be exposed, but for all that it is really a branch of carpentry. As such, we need not discuss it here, save to say it is essential that the wood be seasoned to perfection, and that the curved sides of grand pianos are formed of a great number of strips of thin wood, bent and glued together, huge moulds and cramps being employed in the process. A close study of the chapters on CARPENTRY and CABINET-MAKING will put the student on the right road to learning his calling.

The case being made, it has to be polished, and again the section on CABINET-MAKING will give all needful instruction. We have, therefore, two main processes to study here, the first dealing with the material from which the sound is produced, and the other with the means by which that sound is evolved.

The Sound Mechanism. We will now take the portion of a piano devoted to the making of the sound. First, there is the back, which must be strong, to support all the material which lies on it, or which is attached to it. At the same time it must be of such a form as not to spoil the resonance in any way, for on it lies the soundboard, which forms the second division of this part of the piano. On the soundboard in modern pianos we find the iron frame, which takes up the strain of the strings, over which we have the strings, attached to pegs, passing over certain bridges and between small pins There we have the entire sound-making portion of our instrument.

The back, or under side, in a grand piano is built of well-seasoned wood, sometimes of best English oak, and occasionally, in cheaper instruments, of beech. It consists of stout framework, carefully mortised together, with bars across at different points. In English upright pianos these bars are usually vertical, and seven in number; in German pianos the bars run diagonally, as they do in most grand pianos. The oblique bars are said to give a smoother singing tone to the instrument, but they are not conducive to great durability. The making of these bars is, it will be admitted, merely carpentry. The calculation of their thicknesses, and the selection of their positions with a view to the quality of sound desired, is the work of a practical and theoretical acoustician. To this back, or under side, is attached the soundboard.

The soundboard is constructed of lengths of the finest spruce fir, similar to that of which the bellies of violins are made. These lengths are glued together with the greatest care, just as the belly of the violin is joined, and the direction of the wood is so arranged that, where possible, the entire length of both the bridges over which the strings pass shall lie on a single plank. The selection of the wood for the soundboard is a matter of much judgment, for on its resonance depends the greater part of the tone of the piano. Need we say that the wood, like that of the violin, must have a tone of its own?

A moment's thought will show us that the strings must exert an enormous downward pressure on the bridges, and therefore we must fasten the belly-bars across the under side of the soundboard to resist this pressure. The grain of these bars must run in an opposite direction to that of the wood of the soundboard itself. The bars are also necessary from an acoustic as well as a mechanical point of view. Anything like proper vibrations in the soundboard itself would be exceedingly undesirable, and these bars serve to prevent such being established other than by the vibration of the string.

Modelling the Soundboard. The soundboard, when the lengths of pine have been glued together, is the object of the most scrupulous care of, perhaps, the most highly trained man in the entire piano factory. The soundboard of a good piano has to be modelled most carefully. It is of a more or less convex shape, the rise being towards the strings, and it tapers gradually away in various directions, the thickness

being suited to the string which will lie over it. No fixed rule can be laid down for this tapering, nor for the thickness of the soundboard at any one part, each maker having his own private formula, preserved as a secret, which gives to his instruments their individuality.

After the soundboard adjuster has done his work, scraping, chiselling, and planing here and there till the wood gives out the right ring when he taps it, and till his callipers tell him his thickness all over is right, it is covered with several layers of varnish to prevent cracking and warping. The varnish used affects the ultimate tone, just like the varnish of the violin-maker, and differs with each firm of makers.

The "Wrest Plank." Above the top of the soundboard in cottage pianos, forming, as it were, a border to it, and at the lowest end of that of grands, separated from it by a small space, is a massive log of hard wood, generally made of layers of beech or oak, the grain of each successive layer running across those of the previous one to prevent splitting. This block is also very frequently further strengthened by a metal plate.

When we mention that the function of this plank is to hold the pegs by means of which the strings are tightened, the necessity for this care becomes evident. It is known as the *wrest plank*, and the pegs are called *wrest pins*.

The Bridges. Across the face of the soundboard are two bridges made of hard wood. It is through these that the vibrations of the strings are transmitted to the soundboard. The distance between them varies with the length of the string. The one farthest from the wrest plank is called the belly bridge, and is made in two parts, that taking the covered bass strings being separated from the bridge for the smaller strings. If the detached portion of the belly bridge is so placed that the bass strings have to lie over certain of the other strings, then the piano is spoken of as "overstrung." The second bridge, or wrest plank bridge, is placed close to the wrest plank, and in grand pianos the wires are pinned down to it, to prevent their being in any way shifted by the impact of the hammer, which in this class beats the string away from the soundboard, but in uprights drives it towards the belly. These bridges are firmly glued and screwed on to the soundboard.

The Iron Frame. Above all this is placed the massive iron frame, which has to withstand the enormous strain of the strings, a strain which, in large concert grands, approaches 30 tons. The iron frame is cast of the best hard metal, carefully finished by mechanics. It is attached to the wrest plank, soundboard, and back. At one end it bears the pins to which the fixed ends of the strings are attached.

Across the iron frame are bars, the direction of which differs in almost every make of piano. These are simply mechanical contrivances for enabling the frame to withstand the pressure upon it. The iron frame is bolted into its place by massive bolts and screws.

Stringing. When the piano has reached this stage it is taken to the stringer, who is often a youth destined later to become a tuner or regulator. He begins to put on the strings, placing the loop over the end pin and the free end through the hole in the wrest pin, which he then hammers into its hole and tightens up slightly.

The strings being all in place, the body of the piano passes to the "chipper up," who is an elementary tuner. This workman, or artist in embryo—for he is in the first stage of skilled work—starts to tighten up the strings into some sort of tune. To get the sound, he chips the strings with a piece of ivory, twanging them like the strings of a mandoline. He does not start at one end of the piano and work right through, but, "setting" a scale in the centre, tunes roughly from that, as if tuning a proper piano. This prevents the strain from being put on one end suddenly, leaving the other loose, a proceeding which would damage the piano. [See PIANO TUNING, page 6024.]

Stretching the Strings. The instrument having been brought into some resemblance of tune, a piece of board, covered with leather, is taken and pressed with great force up and down the strings to stretch them and, as far as possible, remove all spring in them.

After this operation it will be found that the tune has vanished, and so the piano must be re-tuned, being brought almost up to pitch. It is then left for a few days, and then again tuned to pitch. Four or five such tunings will be necessary before the tune will stand, and only then is the piano ready to be tried with the action. This chipping up is generally done after the back, soundboard, and so forth, have been firmly screwed into the case which is to contain them.

The Action. Very few piano-makers in this country make their own actions; unfortunately, most of them depend on the Continent for the supply of very second-rate mechanism. A few firms, however—not half a dozen, alas!—prefer to manufacture their own, and the result is that their pianos contain sounder and better actions than any made abroad.

The bulk of the action for the best English makes of pianos is cut out of the finest and hardest French hornbeam, a wood with very little grain, and one which works as cleanly as metal. It is little affected by moisture, and consequently actions made of this material rarely stick, provided they have been properly made. Foreign actions, produced in a violent hurry and badly finished, manage to stick, even when made of hornbeam. Beech is used for a few parts, and English oak is used for the action rails running right across the piano, against which various portions rest, or to which portions are screwed.

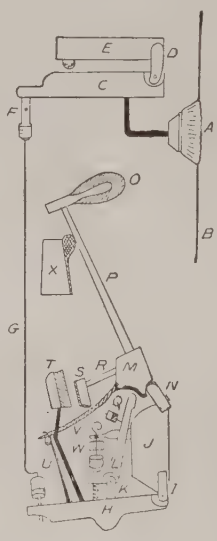
Of actions there are many, but as examples we will take two typical actions for upright pianos—namely, the over-damper check action and the under-damper check action, with a tape. These are named according as the damper is over or under the hammer. Of actions for grands we shall not treat, because, until the beginner has mastered the fitting and regulating of upright pianos, he will not be entrusted with the more costly action of a grand. We will, however, indicate the principle upon which the grand action works.

The actual making of the component parts of an action is accomplished by machinery, the work being so subdivided that unskilled labour can be employed to an enormous extent. Thus, one operative will do nothing but pass wood into the sawmill; another will be solely engaged in boring holes in one particular part of the action; a third will give the correct bend to the various wires used, and so forth, each operation being performed on machines fixed to an exact gauge, so that error cannot possibly creep in. Only when all the individual parts are ready to be assembled does the skilled man step in.

Where, then, does the superiority of the English action come in? In attention to detail, and in the quality of the accessories which are indispensable

to the proper making of actions. We will indicate one small particular. The holes through which the tiny wires which act as hinges for the moving parts of the action should be lined, or "bushed" with cloth. In Continental actions this is never done so efficiently as in English actions, with the result that, after a time, the mechanism rattles, and rebushing becomes necessary if the piano is to work properly.

Over damper Actions. The portions of an over-damper check action are best understood by reference to the accompanying diagram [1]. It will be seen that there are in reality two distinct motions, to be accomplished by two sets of levers operated initially by the primary action of the end of the key lever. The first motion is the withdrawal of the damper A from the string B, by the combined actions of the damper lever C, which is hinged on to the damper flange D, and checked in its turn by the damper rail E, to which also the flange is screwed. All flanges and parts screwed to fixed rails are fastened by one screw only, but, to prevent them from shifting, are provided with a groove across them, into which fits a raised bead on the rail. The damper lever is lifted by the damper lifter F, moved by the damper wire G, which passes through the base of the end of the jack rocker H. The wire is free in its hole, and has its button screwed upon it, on which the jack rocker presses to lift it. When the sustaining or loud pedal is pressed, by an arrangement not shown in the diagram, C is lifted, and so the dampers are moved away from the strings. The end of G, being loose in H, enables the jack rocker to move, when the key is struck, without affecting the damper at all. At the knob shown on the lower part of the jack rocker, a rod is fixed, which is pushed up or down by the direct action of the key.



1. OVER-DAMPER ACTION
[For explanation, see text]

The jack rocker may then be considered as the junction of the two systems of levers. It is hinged by means of the jack rocker flange I to the hammer flange rail J. Almost above the lower protuberance in the diagram is fixed the jack flange K, carrying the jack L, the upper end of which presses on the hammer butt M. The hammer butt is fixed to the hammer flange rail J by the hammer flange N, and on being pushed upwards by the jack, tilts the hammer O, carried by the shank P, against the string B. The little spring under the foot of the jack is to keep that part close against the hammer butt, and the jack is prevented from coming too far forward by the jack check rail Q, seen in section. The felt on this rail is adjustable by means of a screw. R, S, T, U, and V form the check system, and are named respectively the back check shank, the back check, the back catch—on which the back check hitches when the hammer is far enough forward, and which regulates the rebound after a stroke—the stirrup wire, and the tape. The tape keeps the hammer from going too far forward, or from sticking close to the string after the key has been raised. W is the escapement rail, with screws and buttons for regulating, and X is the hammer rest, covered with padding against which the hammers lie.

Each of these distinct parts is made separately, and only assembled at the last minute. The curved and shaped pieces of hornbeam are first of all planed to shape with moulding planes, a whole strip some 6 ft. long being dealt with at a time. This is then cut up into sections by means of a revolving saw driven at very high speed. The sunk grooves, where the joints work, are then cut to a regular depth by another machine cutter, the depth being regulated by gauge. After this, the holes for the pins are bored, and then the holes are lined or bushed.

Lining the Holes. The bushing is done in this way. A strip of superfine cloth, known as "Mechanics' Cloth," and costing about 20s. a yard, is prepared of such a width that if forced into the hole its edges will just meet. These strips are cut by machines. The strip is rolled up spill-wise and the point drawn through a hole, and then through a second, and so on, till the strip of cloth is threaded through as many pieces of bored wood as will go upon it easily. Just as the cloth is drawn through the outside is slightly smeared with paste, to hold the bushing in the hole. When the strip is full, the various sections of wood are separated from one another by cutting the cloth with a sharp chisel, and when the edges are trimmed the holes are all neatly bushed. The bushing is then just opened for the pin by means of a needle. The shanks are made by drawing strips of wood through a revolving series of cutters, the strip emerging as a round stick, which is subsequently sawn up into lengths.

The base of the hammer butt, where the jack impinges, and the face of the back check are faced with very fine doe skin. This skin is far better than sheep skin, which is commonly used abroad. It must be shaved down to one regulation thickness before being cut into strips for the purpose of being glued into place. It is often advisable to fasten a piece of thick felt or cloth behind corners covered with this leather, as the shock is thereby softened, the action improved, and the life of the leather greatly prolonged. The felt for the hammer head is woven specially to a taper, and only requires bending and gluing into position, being pressed down with heated curved irons.

Fitting the Action into Position. When sufficient sections have been collected to make up an action a fitter builds them into position, by screwing the various flanges on to the rails attached to the action frame, which is made to fit the particular piano to be completed. Then he sees that each individual action works smoothly, and by means of the regulating screws gets all the levers to have about the right amount of play, leaving the final regulating to the expert later on.

In another part of the shop the keys have been sawn out, and the ivory or celluloid attached. Ivory, of course, cannot be bent, but celluloid can be bent by heat, and thus made to cover the top and ends of the keys. The holes for the pins and pivots are bored by machinery and the portions of the keys which play on the rod of the jack rocker burnished with black lead, or covered with felt or leather, according to the method employed by the particular maker. Then the keys have holes bored in them and lead weights inserted, of sufficient size nearly to balance the entire key at the pivot when in contact with the action and the

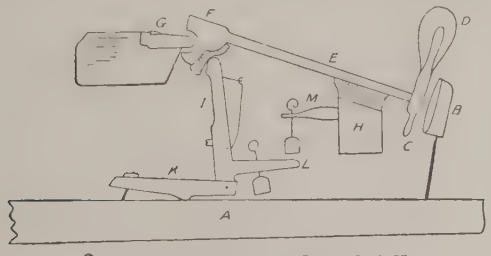
hammers lying back. The damper lever of over-damper pianos is also generally weighted, to ensure the damper falling forward on to the string as required. These weights are cast so as exactly to fit holes bored in the wood for their reception. The fitting must be done very neatly, lest a rattle should be set up.

All these adjustments having been made, and the keys placed on the key bed, and brought to a proper level by means of washers, or punches as they are sometimes called, placed under the keys round the pins, the action can be placed in position in the piano, and the instrument handed over to the regulator. At this stage the rail which is to lift the dampers is connected to the pedal levers which have been fitted inside the case, and the damping felt can be attached to the action, if the soft pedal is to be operated in that manner.

Under-damper Actions. The under-damper action, which we illustrate [3], is very similar to the over damper, save for the actual damping arrangements. The lettering of the hammer and check mechanism will, therefore, remain the same as in the previous illustration. The damper alone will claim our attention, together with the means of operating it.

In this action it will be noticed that the damper is inside the hammer mechanism, and the damper lever, which is in one piece, and marked A, is operated by a portion of the jack rocker on the opposite side of its hinge to the hammer mechanism. Did the end of the jack rocker touch the end of the damper lever, then, when the key was depressed, the end of the rocker would fall away from the lever. This would not work the damper. The damper lever is attached to the hammer flange rail by the damper flange C, and the lever has a small spring bearing against it, just sufficiently hard to press the damper firmly against the spring. The end of the lever, near the rocker, is covered with fine leather, and sticking upright in the end of the rocker, lying close to the end of the lever, is a small metal rod, flattened out into the shape of a spoon. This is marked Y.

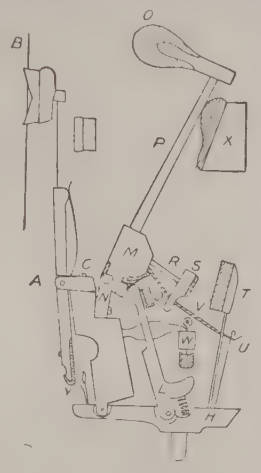
By means of a screw passing through the bottom of the lever the leather facing can be made exactly to graze the smooth surface of the spoon when the hammer is at rest. If, now, the jack



2. SQUARE AND GRAND ACTION
[For explanation, see text]

rocker be lifted by the depressing of a key, the end of the rocker beneath the lever will fall, but in so doing will thrust the spoon a little forward. The forward movement is not very great, but it is sufficient to enable the spoon to press against the leather-faced end of the lever, and so to lift the damper off the strings. On the key being released the spring returns the damper to the string. In this class of action the loud pedal mechanism may be of any kind which will press the entire set of dampers back from the strings a fraction, and may operate either above or below the damper flange.

Actions for Use in the Tropics. There is a new pattern action, invented in the past few years, for fitting to instruments intended for use in hot climates, which is excessively simple, while at the same time it is most efficient. In it the key acts directly on the jack rocker; the jack is very long indeed, and carries two projections on it at an interval of about 1½ in. distant. The lower one operates an over-damper action of the pattern shown in our former diagram. The inner and upper one carries the back catch, which in this case has the felt facing outwards. The hammer butt carries the back check, which is on a wire bent over the back catch, and with the leather facing turned inwards. The top of the jack acts direct on the hammer butt. By this means it will be seen that the friction, and consequent sticking points, are brought to a minimum, and there is much less padding for insects to destroy. The touch of these frictionless pianos is very delicate and they are fast becoming popular. In place of a tape, a small loop is attached to the hammer butt, and this hooks into a curved spring fixed in the upper part of the jack, the spring serving the double purpose of pulling the hammer back, and keeping the jack close up against the butt.



3. UNDER-DAMPER ACTION
[For explanation, see text]

Grand Piano Actions. The actions of grand pianos, as we have already said, are exceedingly complicated, but the principle which underlies their construction can be gathered from our diagram [2], which represents the action of an old square piano. It will be noticed that the key itself carries the back check, and the back catch is a prolongation of the hammer head in a downward direction. The jack rocker rests directly on the key lever, and the escapement lever, with its button and screw, also acts on the key, and, as well, on the set-off button attached to the escapement rail. The damper, which is above the string, may be raised by a wire fixed into the key lever at any point between the rocker and the back check. The parts are these:

A is key lever; B is back check; C is back catch; D is hammer head, and E hammer shank; F is hammer butt; G is hammer flange; H is hammer rail; I is jack, with spring and silk loop passing through jack or round it and attached to hammer butt; K is jack rocker; L is escapement lever and regulating button; and M is escapement rail with regulating button, or set-off button.

Regulating a Piano. The first thing the regulator does on having a piano handed over to him for adjustment, be it old or new, is to see that all the keys are perfectly level. If they are not, he places paper or cloth punchings, or wads on to the centre pin till all are exactly level. This will not,

as a rule, be necessary with a new piano, but it is mentioned because it frequently has to be done to old instruments. If the keys are too loose on the front holes the oval guide pins can be turned a little till they have free play, but are not able to shake. The depth of the touch is then tested. It should be about $\frac{3}{8}$ in. deep in the middle registers and about $\frac{1}{32}$ in. deeper or shallower in the bass and treble respectively. The correct depth can be arrived at by placing cloth or punchings under the middle rail to make the touch deeper, and under the back or front rail to make it shallower.

The Position of the Hammers. The regulator next sees that all the hammers are level and properly spaced, so that they strike the strings fairly. In a new piano, made with an English action, he will not find alteration necessary; but when a foreign action is fitted, he may have to shift one or two hammers a little. The jacks must next be adjusted close under the notch in the hammer butts, and this is done by turning the regulating screws; but the jack must not be raised too much or the note will fail to repeat in rapid passages. The proper position is immediately under the notch, just touching it lightly, so that the slightest touch on the key raises the hammer.

Next, the "set-off" must be seen to. The set-off of a note is the distance to which the hammer is raised by pressing down a key. In a properly regulated piano the hammer should advance to within a quarter of an inch from the string in the centre notes. In the bass it should be rather farther away, and in the extreme treble a little closer. Only experience can teach the exact ideal positions. The set-off is regulated by turning the regulating screw with a small hook till the hammer advances the proper distance.

That done, the back check and catch must be arranged by bending the wires till the check just catches the hammer and holds it for a second when the hammer rebounds from the string; this is to enable the jack to recover itself and get into the notch beneath the butt again. At the same time the check and catches must be adjusted so as to prevent the hammer from falling back too far from the string. About twice the distance of the set-off is correct, though some make the hammers fall back to $\frac{1}{2}$ in. all over the register. This must be properly adjusted or else the piano will not repeat with accuracy.

The damper action must next be seen to, and in an over-damper the wires should be adjusted by turning the buttons so that there is a play of about $\frac{1}{32}$ in. between the button and the end of the jack rocker. In under-damper actions the dampers do not often require touching, being adjusted in the shop. If, however, the dampers do not lift readily, or if they lift too much, the screw which passes through the lever end and presses the felt or leather out towards the spoon can be turned till the damper is correctly moved by the depression of a note. There should be a little space between the spoon and the lever tail when the action is at rest. Next, the action of the pedals must be seen to, and any friction overcome by using blacklead. When all works smoothly, it is time to tune the piano.

PIANO-TUNING

In all keyboard instruments tuning is a far more complicated process than it is, for example, in the violin, which has but one string for many notes, and not more than four strings altogether. In the piano, instead of four lengths of catgut, there may be upwards of 200 steel wires strung across an iron or steel framework, the total tension, according to the size of the instrument, being approximately from 15 tons to 30 tons. Attention to so many strings would alone demand more time than any professional pianist has to spare.

Unisons. The knowledge most usually required is that for pulling up and adjusting a new string. First, the broken string must be extracted. To do this in an upright piano (we are not speaking of grands), take off the front. First turn the buttons inside the top panel at the bass and treble ends; draw the front forward, lift it out; turn back the cover or cylinder over the keys, and lift it out. If the front and cylinder are joined, both come out together. To remove the action (or hammer mechanism), turn the buttons at either end of it, or undo the thumbscrews. Grasping the hammer rail, draw forward the action. Lift it up out of the sockets and place it on a table, or in some other convenient position. Unfasten the catches under the keyboard. Draw the bottom door forward and take it out. In an upright piano, the gauge for strings varies from treble to bass, from No. 9 to No. 21, the sizes of wire being marked below the tuning-pins. In a trichord cottage, the pins are placed in threes, one over the other. If one string serves for two pins, the bottom pin of one note and the top pin of the next, or the two middle pins of neighbouring notes, will need new wire. Having obtained the necessary length (by sending the old wire to a maker as a pattern), bend one end of the steel into a loop $\frac{1}{2}$ in. long. Twist the end round twice, and clip it off with a pair of cutting pliers.

"Chipping Up." Place loop on hitchpin, projecting from the iron frame at the opposite side to the tuning-pin. Fit the string between the two pins in the bridge, alternately inside the first and outside the second. Pass the wire up above the keyboard. Thread the string through the hole in the brass stud, if necessary. Cut off the wire with the pliers 2 in. beyond the position of the tuning-pins. Insert the string through the eyehole of the pin. Put the tuning-hammer or tuning-crank on the latter; twist the pin round twice to the right, making the coil even. If the tuning-pin has been taken out of the plank, drive it in with some smart blows from a hammer till even with the other pins. Now turn the hammer round to the right, "chipping up" the tone of the new string with a piece of bone or a mandoline plectrum until it is in unison, as regards pitch, with the other wires belonging to the same note. After taking off the hammer, replace the action. With the right hand, readjust the hammer to the tuning-pin, and with the left try the note on the keyboard. Listen attentively to the throbbing of the vibrations. Gradually turn the hammer to the right until the quick and uneven beats merge into one steady and clear sound.

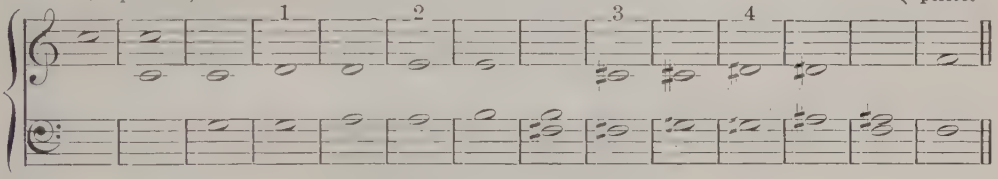
An identical tone is the easiest for the student to begin with. In trichord pianos, where three strings go to each note, two-thirds of the total are so tuned. When the throbbing has resolved into a steady vibration, the new string will be in unison. To ensure that the note will stand, "set" it by striking the key sharply to ascertain that the wire does not slip through the stud nor over the bridge. If it does, repeat the tuning and the proof till the note holds firm.

Octaves. If a new string put on is a single one of covered wire in the bass (the steel core being overspun with copper), it must be tuned by the octave note above. Strike these two notes together. In point of importance and facility, the tuning of

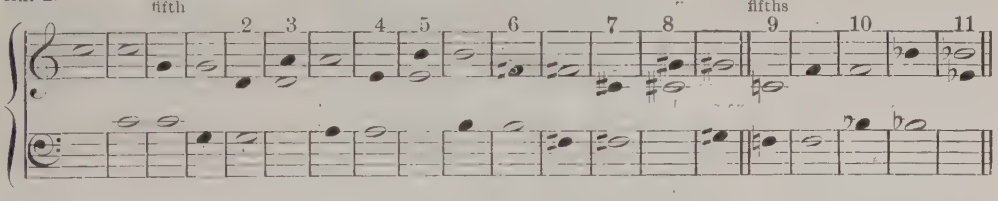
the octave, so far as the student is concerned, comes next to the perfect unison. Though no longer identical, the sounds resemble each other strongly. Turn the hammer on the pin of the new string gradually to the right. Listen attentively. At first the beats will be uneven. When the lower string reaches its proper tension, the two sounds will cease to vibrate unevenly, and the compound tone then produced will blend smoothly. Take care not to raise the new string above the pitch required, or it may break; neither put any side pressure on the tuning-pin, or it may snap off. Avoid turning any pin unnecessarily, otherwise it may become loose, and naturally a piano with loose pins cannot stand in tune.

"Laying" a Scale. In this country tuners generally lay the scale from C (third space, treble clef). On the Continent the start is made from A (second space, treble clef). It is the tuning-fork, therefore, which gives the initial tone. The correct pitch of the latter is thus of paramount importance.

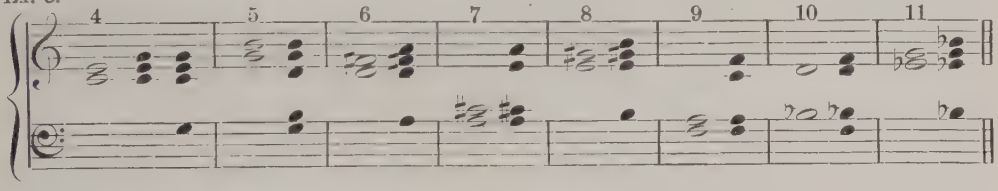
Ex. 1. Pitch C — Octave perfect — All fifths a wave flat — Octave perfect



Ex. 2. 1st fifth — Back fifths



Ex. 3.



Pitch-pipes are not recommended, as they are frequently inaccurate. What is known as *concert pitch* is a nebulous term. In England there is the Kneller Hall sharp military pitch, the low French pitch, and the Society of Arts (or medium) pitch between the two extremes, besides other fanciful standards used by various piano-makers. Accurately measured tuning-forks are difficult to get at an ordinary music-shop. The point is to get a fork at the new pitch (stamped "C 522" double vibrations per second), not the old Philarmonic pitch (C 540), as the latter is considerably sharper, and puts a greater tension on the strings of the piano, as it does on the voice of a singer. In addition to a tuning-fork, when tuning a trichord instrument three wedges are needed. These consist of narrow strips of whalebone, or pliable wood, ¼ in. wide and 9 in. long. The ends are padded with one or more layers of wash-leather, the thick tip being for unisons and the thin for octaves. From the front, carefully insert a wedge obliquely through the action, so as not to touch the hammer striking the note to be tuned.

Having wedged out two of the three strings of pitch C, put on the hammer. Sound the tuning-fork by striking one of the blades smartly on the knee with the left hand. Place the small end of the fork on any portion of the woodwork in front of the piano. To the sound it gives, C, third space, treble clef, must now be tuned. Raise or lower the pitch of the string gradually until, when the note C is struck, it agrees accurately with the tuning-fork. Stop the vibrations by a wedge inserted between two of the unisons of the C below, and get the octave perfect. Do not strike the lower note too hard at first. The sharp blow is only required for "setting."

There are various ways of laying the bearings of a keyboard instrument. Different tuners naturally pin their faith to the methods which they have been taught and have found most useful. But as all these systems, properly carried out, have the same result in making the tone of the instrument agreeable musically, the student may adopt any one of them profitably.

"Tempering" Notes. Presuming that the pupil is musically inclined, it may surprise him to be told that the foundation of the tuning of all our keyboard instruments is intentionally inaccurate. Let him look at the piano for a moment. Enharmonically, every white and every black note has two names, if not three. C natural serves also for B sharp and D double flat; C sharp is also D flat; D natural likewise is C double sharp or E double flat, and so on. Therefore, if we have twelve keys within an octave, we have to make them serve for upwards of twenty-four notes indicated in music. A very clever violinist with a sensitive ear, or a trombone player, because the tone of such instruments is not fixed, will play in what is called "just" intonation. On a pianoforte or church organ, the only intervals *absolutely* perfect with the pitch notes are the octaves. The rest of the notes are "tempered." For the purpose of practical

harmony, the notes within each octave have been so modified that the acoustical divisions between them have been made as equal as possible.

The ear of the musical student may at first rebel against the mutilation of any interval, but the system of modifying the notes within the centre octave internationally adopted is based on common sense, and has been found the only possible solution of a problem which perplexed musicians for many years. Mathematicians, acousticians, musicians, and manufacturers have written libraries full of books on this subject. It is therefore a difficult one to deal with succinctly, and the reader is referred to Example 1.

After tuning the octave C, it will be seen that the student must proceed to G below. Tune the fourth perfect. Then from this G get the fifth above, D, "tempering" it by leaving it a beat flat. From the D tune the A below a perfect fourth. Then get the second fifth by tempering the E above a shade flat. Tune the B below a perfect fourth. From the B go down to F sharp, and make that also a perfect fourth. Now get the third fifth by tuning C sharp a wave flat. Follow with the fourth below G sharp in just intonation, and then, from the G sharp, get the fourth fifth, or D sharp, a shade flat. Proceed to A sharp, a perfect fourth, and then get a fourth below the A sharp, technically E sharp but actually F natural, and, finally, tune the octave F above perfect.

Unless the "shading" has been distributed equally, the octave will not come out perfect, and to proceed any further with the tuning will only magnify the shortcomings of the bearings. Before equal temperament (advocated by the great composer Bach) was adopted, it was disagreeable, on account of the "howlings," to play the piano or organ in the "black keys"—now the most beautiful. As accurate "tempering" is an art which a beginner cannot learn immediately, his first attempt, when proved by the final octave, has no doubt revealed that his modifications of the fifths have been overdone. Let him, in going over the work again, therefore, check it in a different manner [Ex. 2].

A HANDSOME ORGAN
(Photo Bedford, Lemere & Co.)

Here the scheme includes all the keys on the piano between F natural (fourth space bass clef) and C (third space treble clef). But instead of four fifths presenting themselves, the student can check his work by eleven of them. After the low C, tune the G above a little flatter than perfect. Then prove this with the octave G below, already tuned. From that G, get the second tempered fifth, or D above, and then the third, or A above the D. Now prove this note, which should be a perfect octave with the A below, already tuned. Go over the fourth fifth that now occurs, by checking the E already tuned under the first scheme. Now, get the B above, tempering this fifth fifth a wave flat, and from it prove the octave B below, already tuned.

Next get the sixth fifth, or F sharp above, and from that prove the F sharp below, already tuned. Check again the fifth above low F sharp, with the C sharp tuned according to Ex. 1. Continue to get the eight fifth, or G sharp above, proving it with the octave note below, already tuned. Having arrived at the eighth fifth of the series, the student must return to C. Tune the remaining fifths "backwards," first making the bottom note, F natural, a perfect fifth with the C, and then slightly sharpening it in the same degree that the upper notes were flattened when tuning the other fifths "forwards." By this means the necessary tempering is done correctly, but the lower note is affected rather than the upper. Then get the octave F above perfect. Treat the B flat below in the same way, so as to modify the lower note, and keep the upper one just. Get the octave B flat above, and, finally, tune the eleventh fifth, tempering the lower E flat. Of course, as we have first seen, it is not necessary to tune all these fifths in laying a scale, and there are other ways of checking correct equalisation than the scheme last referred to. As soon as the fifth marked "4" in Ex. 2 is reached, the C below gives the major third; and if this third is slightly sharper than perfect it is an indication that, so far, the tuning is correct. In like manner test each subsequent fifth by means of the triad [Ex. 3].

Extending Operations. Upon the bearings laid the rest of the tuning is built up. The unisons, or two other strings, of each first one already tuned must be made to accord (altering the position of the wedge) until each group of three strings blends properly together in sound. This done, proceed to the octaves. Begin on C sharp (first ledger line beneath treble clef), and tune in succession one string of every octave note above until the extreme treble of the keyboard is reached.

All octaves must be "perfect." Then take the E below middle C, and tune each successive note in octaves down to the extreme bass. This done, go over the treble octaves again, as they are apt to fall in pitch as the tension increases on the lower part of the frame. Finally, try together double octaves, to see that all are accurate. Having adjusted all these notes on one string of each group of three, proceed to tune in unison the second and third string of every note. Taking these separately, adjusting the wedges as explained, get all unisons correctly above and below the central octave. To get increased brilliancy and fullness, some tuners pull the high notes a shade sharp, and leave the extreme bass a trifle flat. On completion of the work, clean the keys with a soft cloth slightly moistened with warm water, and replace the front.

Apprenticeship. In every large piano factory labour is much systematised, so that one instrument passes through many hands, each man being a specialist in his own branch. Particular attention is always given to the tuning department, because the best-made piano in the world badly tuned will sound at a disadvantage beside one of inferior make finely tuned. But to take off experienced tuners to teach beginners deprives a factory of skilled labour which has a definite

value. Therefore, considering how difficult it is to find remunerative employment for many young men nowadays, the privilege of being taught the art of tuning is gladly paid for by parents when their sons are indentured as apprentices. To acquire the necessary flexibility of finger and perception of wave-beats for good tuning, it is essential to begin in early youth, when a lad is still growing. When the wrist is once set, it is seldom possible to make what is known as a fine tuner. The usual age for beginning is sixteen. Obtain an introduction to the manager of some well-known factory and get put down in the "waiting" list. Premiums vary from £5 upwards. Apprenticeship is usually for seven years.

Entering the Factory. The first work is to assist with odd jobs the qualified tuner who acts as instructor, when not employed in "chipping up." By keeping his eyes open the young apprentice can learn much in a factory in many departments, as his work will not always be in the same shop. "Rough" tuning is generally done in the noisier departments where, in case-making or marking off, there may be a good deal of hammering, and a sub-tropical atmosphere. As the lad improves in his work he will be promoted to quieter regions, giving him an insight into hammer-covering, and ideas as to the latest method of polishing. After a certain length of useful service the beginner will receive a small weekly salary. According to ability to tune, this will rise from 5s. to £1 a week.

When the term of apprenticeship expires, an ambitious young tuner will endeavour to get a few years' outside experience. Vacant situations are announced in the various musical papers. Consult the foreman tuner, or factory manager, regarding the status of advertisers before accepting any offer. After an apprentice has done well, the manufacturer will usually be agreeable that he should seek to improve himself practically in some music-shop, where he will come into contact with instruments by other makers, and learn to repair harmoniums, American organs, or piano-players in a way seldom possible in any one factory.

Concert Piano Tuning. The laudable ambition of many a young tuner is to do concert work. This, of course, demands the most artistic skill. Having gained outside experience and, subsequently, been received back on the staff of the firm where he was apprenticed, he will find, if the opportunity is given him, that concert tuning entails considerable responsibilities. It involves, during a tour, the constant packing and unpacking of a heavy iron grand, placing it in and removing it from various provincial halls, besides attending each performance after smoothing over the tuning of the instrument. At the concert it is the duty of the tuner to open and shut the piano before and after each solo, and turn over the music in concerted pieces. Yet it brings him into personal contact with some musician of distinction whose good word may be of considerable value. The weekly wage will probably be £2 2s., with an allowance for travelling and hotel expenses. A report should be made on each concert and sent by postcard to headquarters.

THE ORGAN

Organ building is a branch of the trade by itself. It is sometimes held to be the highest branch, but only on the grounds that the organ is the largest of instruments, for though the work in organ building must be accurate, the same exactitude in measurements is not necessary as that essential in making, say, a violin or an oboe. The organ builder, however, must add to his other qualifications that of an engineer and architect, for he has, as a rule, to build his instrument to fit some selected spot, and cannot make his instruments to any regulation shape or pattern. The trade is of such magnitude that we shall not attempt to do more than indicate the general principles followed, and we shall have to assume that the reader is a first-class carpenter to start with. Such he can become by studying the articles on that subject in this work [see CARPENTRY].

The organ builder, let us assume, has received a specification for an instrument to be constructed. The specification is a list of stops required, of mechanical accessories, and of methods of blowing, and so forth. The first thing to do is to plan out his organ, after taking measurements of the space which is at his disposal. Let us suppose that the space to contain the instrument is ample, so that he can build to suit himself to a large extent.

Now, an organ consists of bellows, a windchest, a soundboard, action for letting the wind into any particular pipe when the key is depressed, and mechanism for bringing various sets of pipes into use, and, lastly, the pipes themselves which give the notes.

The Question of Size. The size of the organ depends on the number of pipes to be used—that is, on the stops with which it is to be provided, and, if proper space is permitted, to avoid any makeshift arrangements, the general size of the organ will be regulated by the size of the soundboard, or soundboards, for the pipes stand on the soundboard. The organ may be entirely built on one very large soundboard, the great organ pipes being at the back and sides, the swell in the middle, covered by the swell box, and the choir, if there is one, in the centre and front; or each of these manuals, which are in reality separate organs, may have its own soundboard, as do the pedal pipes in most organs. So the organ builder, knowing the dimensions of the pipes of each stop, sets to work to make careful drawings of his soundboard, and so to arrive at the necessary measurements for it. Around this soundboard, or number of soundboards, the organ is built up.

The Pipes. The pipes of an organ are of two main classes—namely, wood and metal. The latter are divided into flue pipes and reeds, according as their tone is produced by a whistle-like mouthpiece or by a vibrating reed. The metal pipes are made by a special class of workmen, and are to be bought, or the organ builder makes his own from the sheet. They all have the familiar form, and differ only in length and voicing. The wooden pipes are also of two classes—namely, stopped and open. A stopped pipe gives the same note as an open pipe of double the length, and, as a rule, the stopped diapason is the most bulky of the stops placed on the main soundboards. This set of pipes, then, is first of all aranged for, and then the rest of the board divided up to suit the remainder of the instrument.

How a Wooden Pipe is Made. Making a wooden pipe is simply a matter of good carpentry. The parts are these: A foot, which is a conical, wooden tube, turned in a lathe and bored right through; a block, which closes the lower end of the pipe, and into which the foot conveys the wind to a channel cut across it; and a tube, formed of three pieces of board fastened to the back and two sides of the block, and a fourth with a bevelled edge attached to the edges of the two sides and coming just down to the top front edge of the block; and a

cap, which is a block of wood the size of the block, only broader by the thickness of the two boards. This has a wedge-shaped depression cut in it in such a manner that when applied with the hollow side inwards to the face of the block the thick end of the wedge may receive the wind from the channel and distribute it across the bevelled lip of the front pipe, producing a note. These are glued together, save in very large pipes, when the sides may be screwed to the block, and also the cap screwed on. In stopped pipes there is also a stopper which, when covered with leather, exactly fits the interior of the tube. This stopper has a handle which enables the tuner to pull it in or out at his pleasure.

With minute variations, all wooden pipes are constructed like this, though some have sides like inverted pyramids, and one or two rare stops have actual pyramidal pipes.

The Soundboard. The soundboard consists of a shallow box, divided internally into as many transverse grooves as there are notes on the keyboard, or pedal board, as the case may be. The pipes stand upon holes bored through the top of the box into these channels. The top of the box is made of two layers between which lie long strips of wood at right angles to the channels beneath, and directly under each set of pipes. The holes are bored right through the two layers and the strips, and thus it is clear that any wind in the channels can pass into the pipes above and make all sound. But if one or more of the layers be pulled out, or pushed in for an inch, a plain portion of the wood will intervene between the two bored layers, and the entire range of pipes standing above the layers thus shifted will be silenced. The drawing out or pushing in of these slips is controlled by the stops; when the stop is pulled the valves are opened, and closed when the stop is pushed back. In making this arrangement, the joinery must be perfect and the intercepting sliding parts accurately fitted lest the wind escape, and the tone of the organ suffer.

The upper table of the sound-box is conveniently made from sound boxwood, and the bars forming the sides of the grooves of good pine. The slips of wood which govern the admission of air to the ranges of pipes are cut from good pearwood, or other similar hard wood. They are termed sliders. Between each pair of sliders are strips of wood to prevent the air passing to a neighbouring set of pipes. These are termed *bearers*, and are glued between the two upper boards. It is needless to say that the upper boards need not be of the entire size of the soundboard proper, but may consist of a series of shallow boxes on the top of the soundboard, with the sliders and bearers enclosed within. This is a saving of wood. Also we need not point out that the upper board and sliders for small stops need not be as large as for heavy bass stops, such as those of 16 ft. pitch. The holes are bored through the boards, sliders, and soundboard with good centre-bits or augers.

To support the pipes a certain number of rack boards have to be prepared. These take the strain off the soundboard, and serve to maintain the pipe in an upright position. The holes in the rack boards have to be very much larger than those in the upper board, because they are eventually fixed on legs 5 in. above the upper boards, and so have to sustain the pipe, grasping it by the thick end of the conical mouth. Only the extreme tip enters the upper board. All holes are best scorched with a hot iron after being bored.

When the holes are bored, the interiors of the channels are well smeared with thin glue to close any flaw which may have been started in the process of boring. The sliders and boxes in which they work are best burnished with blacklead, and pins should be set in the slider cases to ensure the slider only moving its proper amount.

The Wind Chest. The wind chest is a shallow box, about 4 in. deep, or more, according to the size of the organ, attached to the under side of the soundboard. It is directly connected with the bellows by means of the wind trunk, a large wooden tube. This box contains the mechanism by which the wind is admitted to any of the channels in the soundboard, and thence to any pipe, for it will be remembered that there is one channel to each of the fifty-four notes of the keyboard, as well as one channel in the pedal soundboard for each of the pedal notes.

The width of the wind chest is governed by the length of the pallets which are to cover a great portion of the soundboard channels enclosed therein. The pallets are the wooden doors, with leather hinges which close the channels normally, and which are pulled downwards when a note is pressed. The back of the wind chest is usually made of a very stout bar of timber, called the wind bar, which helps to support the soundboard and enables it to bear the weight of the pipes.

The Pallets. To each channel is fitted a pallet, freely movable, but capable of firmly closing the portion it is destined to cover. It is kept closed normally by a wire spring, one end of which bears on a bar running the whole length of the wind chest, and the other on the surface of the pallet. The face of each pallet is covered with leather to ensure better closing of the aperture, and a ring or hook is attached to each which eventually is connected with the action of the organ. These rings are placed 1½ in. from the end of each pallet.

The bottom of the wind chest has to be bored at a number of spots exactly under the pallet rings and through the holes wires, known as *pull-downs*, have to pass to open the pallets, but at the same time the wind must not be allowed to escape through these borings. This is effected by fastening a piece of brass on the inside of the bottom board of the wind chest, with holes in it exactly of the size to take the pull-down wires; and along the edges of this brass slips of wood are glued to prevent any wind escaping beneath it. The pull-down wires are then passed through the board and the brass plate, and the ends attached to the pallet rings. The pull-downs must work very smoothly and never stick. All this being arranged, the open portions of the channels on the soundboard which are not covered by the pallets are covered in by gluing sheepskin or parchment over them, making an air-tight joint. The front board of the wind chest is made removable, to enable the pallets to be got at if necessary, but its joints must be made perfectly air-tight.

The bellows are not difficult to make. The form consists of three main boards for each bellows—the middle, top and feeder, as they are termed. There are also a number of thin plates of wood, known as ribs, to strengthen the sides. The whole are united by gussets of skin, and by leather hinges. The feeder must have ample room for play, according to the size of the organ, varying from 10 in. to nearly 2 ft. The upper part of the bellows, or reservoir, must also have the same amount of play, or possibly a little more. The middle board must be a little longer than the other two, so that its ends may rest upon the frame of the organ. It is the immovable base upon which the bellows work.

The middle board has a shallow box, some 4 in. deep, or more, affixed to its upper surface, or the same size as the top board. This is to enable the wind trunk to be attached to the reservoir, and is called the trunk band. In the reservoir there are sixteen ribs, and in the feeder only six, and of these last the long ribs are triangular in shape. The reservoir is made in two stages, the ribs being carried on a light frame the same size as the top board, and the folds are therefore double.

Valves. An opening is cut in the feeder board for the admission of external air, and in the middle board for the transfer of this air to the reservoir. Little bars are fixed across these openings, converting them into gratings, and valves, or "clacks," of white leather are attached thereto. The valves are best made of two thicknesses of leather glued together, and fastened at the edge by a slip of wood and a few brads, thus being firmly held down to the boards. They should fly open at the slightest pressure, and close quite flat. A valve 4 in. square should be made in the top board, opening inwards, and held closed by a stout spring to prevent over-blowing. This is opened by coming in contact with an iron rod when the reservoir is over-distended.

The wind trunks are rectangular wooden tubes, with the joints covered with leather to stop all leaks.

The Action. The essentials of an organ action can best be learnt from the accompanying diagram [4]; but it must be remembered that in nearly every organ various additions have to be made to these plain essentials on account of distance of soundboards from keys, and so forth, for it must be recollected that in an organ with more than one manual, however the pipes may be arranged, each manual *must* have its own perfect action mechanism.

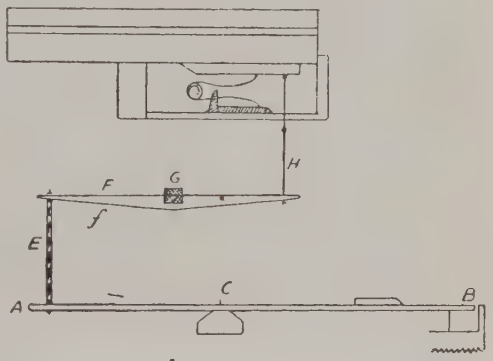
AB is the keyboard, balanced on a pin rail near its centre, and has a pin, C, passing through a little mortise. Another pin keeps it in its place. E is a sticker, or light rod, which pushes, having wires at each end by which it is connected to AB at one end and to F, a backfall, or lever, at the other. F works on G, a backfall bridge. The other end of F, opposite to the sticker, is attached to H, the pull down, which is seen passing into the wind chest, and fixed to the pallet. This is the bare outline of the simplest possible action.

The necessary transference of motion in organ actions often necessitates the employment of rods which pull, which are then called *trackers*, and also of levers of angular form, turning between pins. These in their simplest form consist of rollers with arms projecting from them, and are called *rollers*, the frame in which they are fixed being known as *roller board*.

The mechanism of the stops varies as much as that of the keys, and depends upon the position of the slider which has to be drawn. It resolves itself into a series of expedients for transferring the pull at the organ bench to a pull or push, as the case may be, at any given spot, and in this transference use is made of roller boards, trackers, and stickers. Only a little ingenuity is necessary to work out a scheme for any particular stop in any given position.

The pedal action is only a strong copy of the manual action, and calls for no special comment.

Voicing and Tuning the Pipes. The voicing of pipes is the highest branch of the organ-builder's craft, and cannot be taught save by practical instruction and by experience born of spoiling many valuable pipes. The slightest touch on the lips of a pipe may entirely alter its character. The tuning of organ pipes is difficult, but not so difficult as voicing. The tops of open pipes are cut down, a strip being taken out of the side till the right pitch is arrived at. Stopped pipes have their stoppers pushed in or pulled out till the desired result is attained, while reeds have the steel or brass rod which controls the reed knocked in or out to flatten or raise the pitch. It may be mentioned that two persons at least are necessary to tune an organ, one to manage the keys and the other to undertake the actual alteration of the pipes.



4. ORGAN ACTION

[For explanation, see text]

Reed Organs. Reed organs have bellows of two classes. In American organs the wind is drawn through the tongued reeds into the bellows and so discharged into the air; in harmoniums the wind is forced through the reeds from a wind chest filled by the bellows from a reservoir, as in the case of an organ. The making of the bellows in both only differs in the position of the valves, the one having the feeder with its valve to take air from the reservoir and deliver it outside, while the other has its valves in the reverse position. The spring which governs the reservoir is also reversed.

The reeds themselves in an American organ are in a frame from which they can be drawn by means of a hook. They are tuned by scraping them—at the point to raise the pitch and at the base to flatten it. Their voicing is accomplished by giving them a slight curvature. Harmonium reeds are fixed at the bottom of wind tubes leading from the wind chest, which rests on the top of the reservoir, to the pallets. They are screwed down. Their tuning is accomplished in the same manner as that of American organs, but they do not lend themselves to such varieties of voicing, the peculiar qualities of tone being obtained by variations in the wind tubes, which receive the vibrating column of air.

THE TEA PLANTATIONS OF THE EAST

PICKING TEA NEAR KYOTO

SORTING LEAVES IN CEYLON

SOLDERING DOWN PACKETS OF TEA FOR EXPORT AT COLOMBO

Cultivating Indian and China Teas. Tannin. Coffee Growing and Manufacture. Chicory. Cocoa and Chocolate. Mineral Water Manufacture.

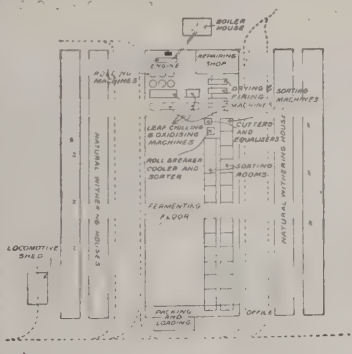
BEVERAGES

TEA is an infusion of the prepared leaves of the tea plant, the species usually employed being the *Thea chinensis* and *Thea assamica*. It was first met with in China, where it is said to have been used four centuries B.C. It was, however, a very common article in the eighth century A.D. Its introduction to Europe dates from the beginning of the seventeenth century, and the import into this country had grown into considerable magnitude by the middle of the eighteenth century, when it became quite a general beverage.

The tea plant is a native of China, and was introduced into India in 1850, but as now grown in India it is generally a hybrid with Chinese varieties.

Tea, as it is put on the market, may be divided into two classes, the green and black teas. This distinction is based solely on the method of manufacture, and is not due, as originally supposed, to a difference in the tree from which the leaves are derived. Both green and black teas are produced in China, Japan, Assam, and Ceylon, although it is usually admitted that the best green teas are made in China [see also pages 5304 and 5306].

Cultivating the Tea Shrub. The cultivated plant is a bushy shrub, not exceeding 6 ft. in height, and somewhat resembling a Portugal laurel. The leaves should not be plucked when the trees are too young, otherwise, when they come to maturity, the yield is much impaired. The plan usually adopted is to pluck the leaves when the plant is three years old; the yield will then be about 80 lb. of tea per acre. The best yields will be obtained from trees which are six or seven years old, when the yield will amount to 320 lb. per acre, although maximum yields, amounting to 800 lb., have been obtained in India. After the eighth year it is preferable to replant. The seeds are usually gathered in October, about a year after the flower has faded, and are then kept in sand and earth until the following March. By this time the seeds will have germinated, and are ready for planting out. Old trees are removed every year and replaced by seedlings. In selecting the ground, attention should be given to thorough drainage and irrigation, for which purpose a good supply of water is necessary. In general, hilly districts are best adapted for the purpose, and the soil should be a rich loam.



1. PLAN OF INDIAN TEA-HOUSE

Gathering the Crops. Whether for green or black tea, the leaves are plucked three or four times a year, those first plucked producing the best tea. The crops are classed according to the age of the leaf, and designated according to their source. Some of the more important are Hyson, Pekoe, Souchong and Congou. Hyson is a term applied in China to the leaf-buds and the first leaves picked in April and made into green tea. Other green varieties are known as "gunpowder," Tankay, and Imperial. Of the black varieties, Pekoe represents the youngest leaf and leaf-buds gathered in April. Sometimes it is flavoured by the addition of orange and other flowers, when it goes by the name of "Orange Pekoe." The same term is applied in Assam as in China. The term "Flowery Pekoe" is also applied to this class. Souchong is plucked next, and is followed by Congou.

Chinese Methods. The manufacture of green tea differs from that of black tea in that it is prepared as quickly as possible from the freshly-plucked leaves, without allowing any fermenting processes to set in. On the other hand, with black tea a certain amount of fermentation is encouraged. The processes employed vary somewhat in different countries, but in the case of green tea they do not differ so much. The leaves gathered in the morning are treated the same day. The first process consists in steaming, with subsequent drying, although in India the steaming process is usually omitted. When dry, the leaves are roasted—that is to say, they are heated in pans over the fire, stirring continuously. The temperature should not rise above 160° F., and the process lasts about five to seven minutes. The leaves, now in a soft, pulpy state, are rolled to break the cells and liberate the aroma; the rolling operation is followed by drying in the sun; and these processes are repeated three times in succession, and then followed by another roasting, after which they are sifted and sorted, and finally roasted again, although the order of the last two operations may be reversed.

In the case of black tea, after drying in the sun and rolling, which may be accomplished either by hand or in the rolling machine, the leaves, in the form of balls, are left to ferment. This process must be put an end to at the right moment in order to obtain the best result, and it is effected by breaking up the balls and spreading the leaves in the sun to dry. This is followed by firing, the leaves being spread on trays with gauze bottoms, heated from underneath by fire or hot air; after firing, the leaves are ready for the market.

Tea Cultivation in India and Ceylon. As by far the greater proportion of tea imported into this country comes from India and Ceylon, we shall describe the methods there employed for cultivation and manufacture.

In March the young shoot, with fresh leaves, or the first "flush," is ready for gathering. This consists of a shoot or new growth bearing the bud and five or six leaves. The pluckers gather the bud with one, two, or three leaves, according to the quantity desired. The buds yield the finest tea, known as "golden or silver tip." The top leaf

produces Orange Pekoe, or, when large, "Pekoe." The second or lower leaf also yields Pekoe, but, when large, Pekoe Souchong (Christison).

The pluckers go round the gardens at intervals of about a week. It is very important that they should avoid gathering leaves which are too coarse, or unripe shoots. The baskets with the leaves are returned as quickly as possible to the tea-house.

Manufacturing Operations. These are as follows [see illustration **1**, showing plan of an Indian tea-house]: (1) Withering or limping; (2) rolling or curling; (3) drying or firing: (4) separating or sorting and cutting or equalising; (5) final firing; (6) packing for export. These operations take together some 22 hours to 26 hours. The withering is carried out in houses built open at the sides, fitted with layers of trays or racks. The object of withering is to remove 20 per cent. to 50 per cent. of the water, so that when subjected to the next operation, the rolling, the leaf is sufficiently tenacious to stand this somewhat rough treatment. The leaves are now taken to the rolling machines. These are of special construction, and give to the leaves the necessary twist, at the same time rolling them into balls. The balls are then broken down.

The next process consists in spreading out the withered leaves on the concrete floor of a large chamber. The chamber is kept dark, and the leaves are covered with cloth or muslin saturated with cold water. In the course of from two to eight hours the so-called fermentation process is complete.

They then pass to cooling and oxidising machines, in which they are spread out on wire-gauze covered tables, through which a current of air is drawn.

Methods of Firing. They are now taken to the tea drying and firing machines. In large factories this is best accomplished in three stages. In the first stage the leaf is passed quickly through an automatic machine which immediately checks the fermentation by exposing the leaves to a temperature of 300° F. The effect of this is to turn them darker in colour, and they leave the machine half dried. The second is a similar automatic drying machine, the temperature of which is 200° F., and on leaving this machine the leaves are almost dry. The third stage is accomplished in a machine under control, so that the operation may be carefully watched. The object of the process is to drive off the moisture as completely as possible without losing the essential oils.

2. COCOA-ROASTING MACHINE

The roasted leaves are next picked over by hand and then passed through a mechanical sorting machine to remove foreign matter, stones, dust, etc. The leaves then pass to circular or revolving sieves fitted with wire of different mesh, so as to separate the leaves into two or three qualities. The general principle of the machine is similar to one which has been already described [see MILLING, page 5273]. The different products are now subjected to a final firing to remove any residue of moisture, after which they are ready for packing.

Chemistry of Tea. The aroma of tea is due to small quantities of volatile oil not exceeding ½ per cent. of the weight of the tea. The peculiar physiological action is due to a substance formerly termed "theine," but now known as "caffeine," as it has been found to be identical chemically with the alkaloid obtained from coffee. Teas also contain a considerable quantity of tannin, averaging from 10 per cent. to 20 per cent. The public analyst is not often called upon to examine teas, as all that is imported into this country is examined by the Customs authorities, and rejected if found to be adulterated.

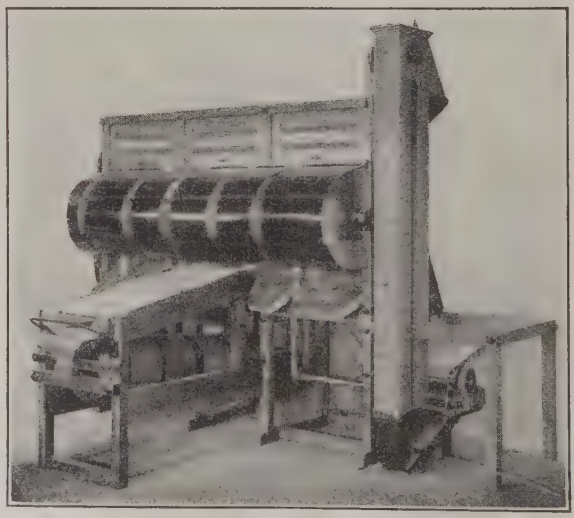
CONSTITUENTS OF TEA-LEAVES

Constituents.	Original leaves dried.	Same made into green.	Same made into black.
Crude proteins ..	37·33	37·43	38·30
Crude fibre ..	10·44	10·06	10·07
Theine (caffeine) ..	3·304	3·200	3·300
Tannin	12·91	10·64	4·89
Hot-water extract	50·97	53·74	47·23
Ash	4·97	4·92	4·93

The proportions of essential oil, caffeine, and tannin vary considerably, and there is also a distinction between the quantities in green and black teas.

A great number of analyses have been made on tea by different authorities. The table given above, obtained by a Japanese chemist, will give some idea of the effect of constituents on the original leaves when converted into green and black tea.

In the above figures it will be seen that the constituent most affected by the process of manufacture

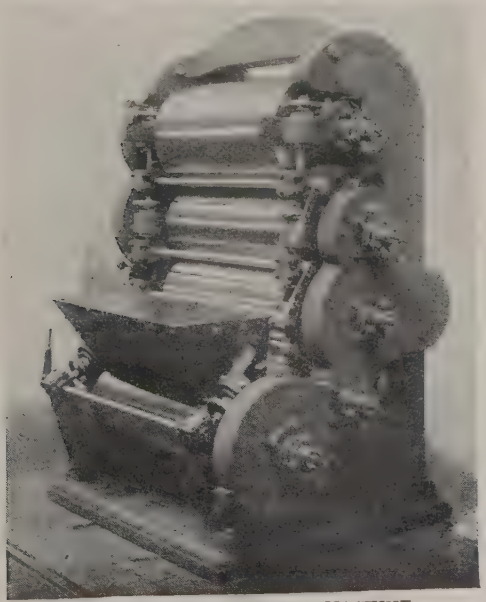


3. COCOA-NIBBING, HUSKING, WINNOWING AND GERM-EXTRACTING MACHINE

is tannin, of which the green tea contains more than twice as much as the black, from the same leaves.

Coffee. Coffee consists of the roasted seed contained in the fruit of the coffee tree (*Caffea arabica*). A number of species and varieties have been discovered, three of which are now cultivated: (1) The Arabian or Mocha coffee, which differs from the others in that it usually contains only one seed in each berry; (2) Jamaica coffee, which has usually two seeds in the berry; and (3) East India or Bengal coffee, characterised by its small berries. The cultivated plant is usually about 6 ft. high, and would grow much higher, but its height is kept down by pruning. It is grown in various parts of the world, generally at some height above the sea-level. It is cultivated in the West Indies, Mexico and Central America, Brazil and various parts of Africa, Arabia, India, Ceylon, and parts of the East Indies, but it is chiefly grown in Brazil. The fruit has been likened to a small black cherry and consists of sweet pulpy matter surrounding one or two seeds, which seeds are themselves enclosed in a thin tough membrane termed the parchment.

Manufacturing Operations. The fruit is allowed to ferment to help the removal of the outer pulp, and the parchment is got rid of by passing the seeds between rollers and winnowing out the husk. The bean is yellowish in colour, and has to undergo a process of roasting to fit it for consumption. The roasting effects two objects—it brings about important chemical changes which develop the flavour; and at the same time the raw bean, which is tough, is rendered brittle, so that it can be more easily ground. The process of roasting requires care; under-roasted beans yield an infusion with a raw flavour, whereas if too strongly heated they are burnt. Usually some sort of rotary apparatus is adopted by which the beans are kept in motion and uniformly heated [see also Roasting Cocoa]. The temperature should not rise above 450°F., and the beans should lose about 18 per cent. of their weight when roasted to a chestnut brown colour.



5. CHOCOLATE-REFINING MACHINE

4. COCOA-GRINDING MILL

The most important constituents of coffee are the volatile oil, to which its fragrance is due, and the alkaloid caffeine which has already been described under Tea. The oil was isolated by Bernheimer from the distillate obtained by heating coffee beans. It is an oil boiling at 195° to 197° C., and has been termed "caffeol."

Coffee is frequently adulterated, and while the substitute generally used is chicory, many other substances have also been employed, including—according to Pearmain and Moor—dandelion root, mangel-wurzel, turnips, beans, peas, flour, and condemned sea biscuit more or less caramelised by baking, and burnt sugar. In addition to this, a patent has been taken out for the manufacture of artificial beans from chicory and other adulterants. Anyone familiar with the bean would have no difficulty in detecting the imitation article, although they are not met with much in this country, it being more profitable to adulterate the ready-ground coffee. On chemical analysis coffee contains about 1½ per cent. of caffeine, 12 per cent. to 20 per cent. of fat, 30 per cent. to 37 per cent. of cellulose, and about 4 per cent. of ash.

Cocoa. Cocoa, sometimes spelt "cacao," is made from the seeds of the *Theobroma cacao*, a tree of some size which grows in the West Indies, Brazil, Central America, and other parts. The fruit is elongated in shape and consists of five compartments containing a sweet pulp in which the seeds or beans are embedded [6]. The fruit is split in two and the beans separated from the surrounding pulp and spread out to dry on bamboo floors exposed to the sun. To rid them of a certain amount of adhering pulp, and also to improve the flavour, they are submitted to fermentation. For this purpose they are placed in wooden barrels, covered over with leaves, and left a day or two. The process is complete when the colour has changed from red to chocolate. The beans are then taken and washed to remove the adhering portion of pulp, and after drying are ready for export. The cocoa seeds or

6. CACAO FRUIT

beans are the raw material for the manufacture of chocolate, cocoa, and various sweetmeats.

Manufacturing Chocolate. The manufacture of chocolate comprises the following operations (Zipperer): (1) Storing, cleansing, and sorting; (2) roasting; (3) crushing, shelling, and removing radicles; (4) mixing the different kinds of beans; (5) grinding the beans until they yield a homogeneous pasty mass when warmed; (6) the incorporation of sugar and spices with the liquefied cocoa mass; (7) trituration by rollers; (8) extraction of air and division and moulding; (9) cooling the finished chocolate.

In general chocolate may be defined as a mixture of pure cocoa (free from shell or germ) and sugar, with the addition of cocoa butter, spices, vanilla, or other flavouring as required.

The beans are first cleaned or roughly sifted, so that the dirt and flat beans are separated out. A cocoa-bean cleaning machine may be used, and the clean beans are delivered on to a travelling web, and any stones or foreign substances which have passed the machine, being about the same size or larger than the beans, are picked out by hand.

Roasting Cocoa-beans. The picked beans are next roasted for the purpose of developing the aroma, gelatinising the starch granules, and rendering the husk or shell brittle so that it is more readily removed; at the same time the astringency is largely got rid of. The plant usually employed consists of a roasting drum similar to that used for coffee, but the temperature required is lower, and should not exceed 130° C. to 140° C.

The illustration [2] represents a gas cocoa-roaster. The revolving drum is heated externally, and the gas is mixed with heated air to render the combustion more complete. The beans are fed through the hopper at the end, and the inside of the drum is fitted with helical blades to ensure the beans being turned over and fed constantly to the centre. The heated gases and steam from the beans escape through the hollow shaft of the trunnion of the bearing.

Separation of Husk and Germ. After roasting, the beans are delivered into a cooler below, the bottom of which is provided with a perforated plate so that air can be drawn through the beans by means of a fan. When sufficiently cooled, the beans are treated to separate the husk or shell and germ from the particles of kernel. For this purpose they are crushed, keeping the pieces of shell as large as possible as this facilitates subsequent separation. The cocoa nibbing, husking, winnowing, and germ-extracting machine is shown in **3**. At the bottom of the hopper is a "nibber," with two pairs of rollers (seen on the right-hand side of the figure) to crack the beans, which are then taken up by the elevator and delivered into a revolving drum made up of six different sections of perforated metal, each of which is somewhat coarser than the last. Each section is provided with a fan which blows away the particles of shell, leaving the clean cocoa-nibs to fall upon inclined sheets fitted to each section. As a small amount of nib may be carried over with the shell, an intermediate chamber is provided, into which it falls, most of the lighter husk being carried beyond. This chamber is fitted with a worm so that the mixture of nib and shell is returned to the hopper for treatment over again. About the centre of the drum the perforations are of such a size that medium sized nibs and germ pass through together. They are conducted to inclined sieves and a perforated drum, by means of which the germ is removed much in the same way as cockle is taken out of wheat [see MILLING, page 5274]. Here it is the particles of kernel lodge in the hollows of the walls of the cylinder, while the germ passes off as tailings.

Grinding and Refining Machines. For whatever purpose the cocoa is required it is essential that it should be finely ground. For this purpose the French form of mill, consisting of two stones, a bed-stone and a runner on a vertical axis, is usually employed. The action of this form of mill has been described in PAINTS AND POLISHES [page 4927]. Figure **4** shows a five-stone cocoa-grinding mill.

The cocoa, which is fed into the middle, leaves the stones in a semi-liquid condition. The ground cocoa is not heated until it is liquid, when it is transferred to a melangeur or to a mixing and kneading machine, where the necessary sugar and spices are added.

The stiff paste is then passed through chocolate refiners. These are built either with inclined rolls or are upright machines with rolls superimposed. A five-roll (chilled iron) vertical chocolate-refiner is shown in **5**. The refining process reduces the chocolate to a smooth condition; it is then usually stored in blocks for some time in a dry room. Illustrations **2** to **5**, and **7** are from photographs of machines by Messrs. Joseph Baker & Sons, Ltd.

For conversion into tablets it is mixed or kneaded as required and passed through a weighing machine, which also compresses it and extracts any air, and thence to moulds. For certain kinds of chocolate, especially if larger quantities of sugar are added, an addition of cocoa butter is made; but for some cheap ordinary chocolate this is replaced by a cheaper vegetable butter such as coco-nut fat, and the outer shell or husk of the bean, representing 20 per cent. by weight of the whole, is also ground up and utilised. Milk chocolate contains a large proportion of concentrated milk, and a smaller proportion of cocoa.

Cocoa Powder. For use as the beverage commonly known as cocoa or "soluble" cocoa, the preliminary processes are carried out as we have already described; but at some stage the material is treated with weak alkalies, such as carbonate of soda, potash, or ammonia, and heated, the effect of which is to modify the cellular matter or saponify part of the cocoa butter in such a manner that, on mixing with hot water, the cocoa remains suspended instead of settling at once (so-called Dutch process).

Some English manufacturers, however, do not use alkali and yet are able to obtain a cocoa quite as soluble as with the Dutch process, but perhaps somewhat lighter in colour, the effect of the alkali being to darken the cocoa when in the cup. French makers are not allowed to use alkali. It is also necessary to remove a large proportion of the oily or fatty matter contained in cocoa—namely, the cocoa butter. This is carried out after roasting by hydraulic presses. Altogether the cocoa butter forms about half the weight of the seed. It is a white solid fat which melts at the low temperature of 30° C., a little below the normal temperature of the body.

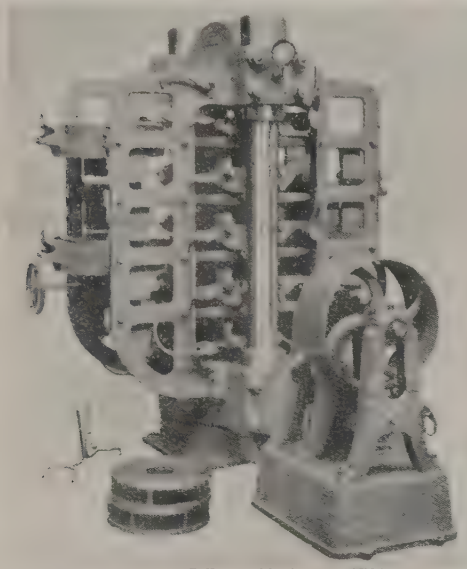
Cocoa contains an alkaloid, theobromine, which is a characteristic and important constituent. It is chemically closely allied to caffeine, but its physiological action is stronger. The amount of theobromine is usually about 1½ per cent.

MINERAL WATERS

Mineral waters may be divided into two classes—natural and artificial. The natural waters are taken from some spring or other source of supply, and consumed on the spot or bottled for delivery direct to various countries. Artificial waters are

prepared by the addition of saline substances and impregnations with carbonic acid gas.

There are also waters which stand midway between these two classes—those which already contain some salts or other dissolved substances



7. HYDRAULIC COCOA-BUTTER PRESS

having medicinal or other qualities, and which are fortified by the addition of further salts or carbonic acid gas.

Principles of Manufacture. Water such as is got by artesian wells from the chalk below the greensand formation in the London Basin is perhaps the best adapted for the manufacture of "minerals." It is soft, slightly alkaline, and very free from organic impuries. The analysis of such a London water made by a well-known expert showed only 0·0004 parts per 100,000 of organic ammonia, 5° of hardness, and six bacteria per cubic centimetre. Such water is practically sterile.

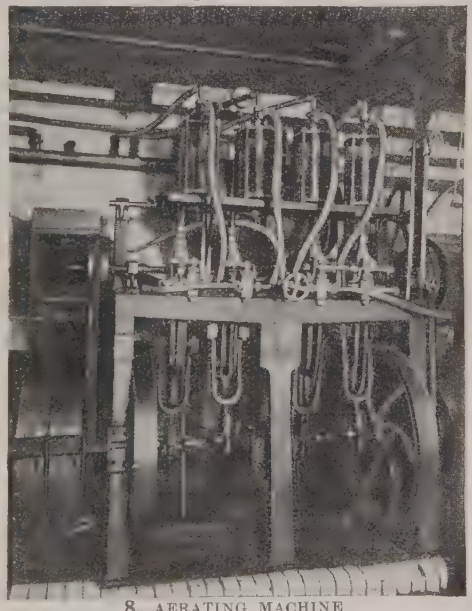
Aeration, as it is called, consists in saturating water under pressure with carbonic acid gas. Water at ordinary temperature, say 60° F., absorbs about its own weight of this gas (if cold, it absorbs more; if warm, less). All bottling is done at ordinary temperatures with cold water. If the pressure on the gas be doubled, the volume is approximately halved; if doubled again, the volume is again halved; but, no matter what the pressure, one pint of cold water (60° F.) absorbs one pint of the gas. If, then, we double the atmospheric pressure by applying 15 lb. per square inch, we get twice the amount of gas into the water. On releasing the pressure, the excess of gas escapes into the air. As ordinary bottling is done at from 60 lb. to 100 lb. per square inch, a large amount of the gas is absorbed by the liquid.

The principles of manufacture, which we will describe in some detail, are chiefly in accordance with those adopted by Camwal, Limited, where the work is conducted under scientific supervision.

Mixing the Gas. The carbonic acid gas used in these works is a natural gas, and is received compressed as a liquid in steel cylinders under a pressure of 800 lb. per square inch. These cylinders are stood on end, and connected up, six at a time, with a receiver resembling a miniature gas-holder. By discharging into this holder, the gas is obtained under a few inches of water pressure. The rate of evaporation from the cylinder causes a portion of the liquid to freeze to a solid, which makes itself evident by frost on the outside. The cylinders are then removed and others attached. The warmth of the air, or of warm water, converts the solid gas back into a liquid, and the cylinders are again placed in contact with the receiver, and the gas completely absorbed by the aid of a warm water-jacket.

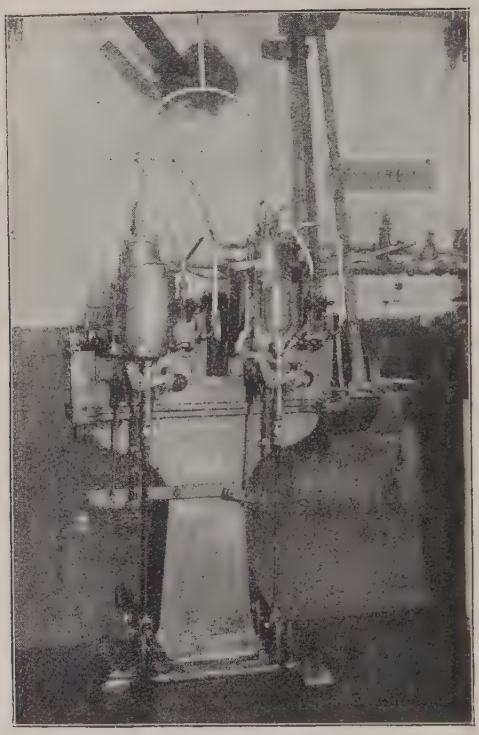
The gas from the receiver then passes through pipes to the aerating machine. Here it is washed as a final precaution, by bubbling through glass cylinders containing water. As the gas contains 99·4 per cent. of pure carbon dioxide, this precaution does not appear to be necessary. The gas then passes through three-way cocks, where it meets with water. These cocks can be so regulated as to supply any proportion of water and carbonic acid gas. The water, the composition of which has already been referred to, is pumped from the deep well into a tank, where, for the manufacture of soda-water, it is rendered alkaline by the addition of pure carbonate of soda. The water has a natural temperature of 56° F. Each mixing tank holds exactly 200 gallons. Bicarbonate of soda is added by means of a suspended filtering-bag, through which the water flows and dissolves it into the tank. The chemist checks every mixing by analysis, as a check to the weighings, the figures of which are carefully recorded.

The alkaline water then passes through silver-plated connections and tin pipes to the various aerating machines above described. It first enters a small feed tank with a glass front, provided with a ball-cock, and then goes to the three-way taps, whence the mixture of gas and water passes into the carbonating chamber. The machine is



8. AERATING MACHINE

made of gun-metal, and is lined inside with tin, ¼ in. thick. With a large machine, the cylinder has a capacity of 80 gallons, and is worked under a pressure of 180 lb. per square inch, the cylinder being half full of water and half full of gas.



9. SYPHON-FILLING MACHINE

Agitation is promoted by a longitudinal shaft provided with triangular perforated paddles, and revolving at 60 to 80 revolutions per minute. The gas and water are pumped into the cylinder by four pumps and four sets of pipes, pairs of which can be worked independently [8].

The water which has thus been ærated thence passes to the filling machine at a pressure of about 180 lb. if required for filling syphons, and 120 lb. for filling bottles and "plain goods"—that is, not containing syrup or sugar—and about 90 lb. for sweet drinks. The actual pressure in the syphons or bottles is about half that at which the water is forced into the vessel. The biggest carbonating cylinder will fill about 1,800 30-oz. syphons per hour.

Filling Aerated Water Bottles. In filling bottles fitted with glass marbles as stoppers the marble is forced into the neck of the bottle by the pressure of the gas inside the bottle.

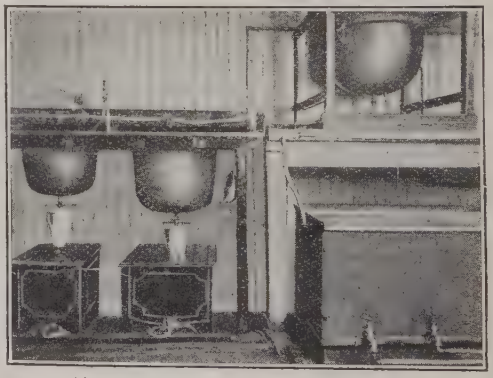
With screw-stoppered bottles, the stopper is screwed loosely into the neck of the empty bottle; it is then placed under the machine, which removes the stopper, fills the bottle, and screws the stopper in firmly.

Bottles fitted with ordinary corks are held in position by the machine and the cork is placed in a holder. When the machine is started working, the bottle is filled, the cork dropped into position, and rammed into the neck by means of a small ram. By the thrust of an arm, the bottle is thrown out of position and pushed down a chute. To avoid "cork dust," the corks are previously washed in water, but as an extra precaution, the ram delivers a spray of aerated water, so as to further cleanse the cork at the moment of insertion. In all the machines, the aerated water is forced into bottles by the pressure of the carbonating cylinder. If syrup is to be added, as in the case of lemonade, ginger ale, etc., it is admitted to small pumps from the tanks above, which deliver at each stroke the requisite quantity to the bottle, which is made up at the same time with the proper proportion of aerated water. All the modern filling machines are fitted with a syrup and aerated water saving device. By this means, no water or syrup can flow unless the bottle to be filled is fixed in its place. In this way, a great deal of unnecessary waste is saved.

When the aerated water is forced into the bottles the air in the bottle is driven out. This is called "snift'ng." In the case of syphons, the "snift'ng" gases are collected and used again, as they consist of pure carbon dioxide left from the last filling, but in the case of bottles they are allowed to escape, as they contain a large percentage of ordinary air.

Syphons. Syphons are filled through the spout. They are fixed so that the spout is pressed against the pipe through which the water is to be admitted. The lever is then pressed down, by means of a small arm actuated by means of a pedal, and the soda-water is forced in so that the pressure in the syphon is equal to that at which the water is entering. The water valve is then closed automatically, and the "snift" valve is opened to allow the gas inside to escape. The "snift" valve then closes again, the water valve is opened, and the syphon is filled up [9]. The gas in the best soda-water syphon contains about 0·6 per cent. of air, the rest carbonic acid. There must not be more than 2 per cent. of air, or the syphon cannot be properly emptied. After the syphons have been filled the tops are burnished by means of a revolving calico disc, and then the body of the syphon is washed and the labels stuck on. The syphon tops of the Camwal Co. are made of pure tin, with only sufficient antimony and bismuth to give the requisite hardness. Some are silver-plated, but this is merely to give them a better appearance, as the tin is absolutely safe.

There are two sorts of syphon tops—*viz.*, those with the long lever, and those with the short ones [11]. With the long lever tops, the lever is raised to deliver the liquid, while with the short valve, the valve is depressed. The former work against a spring, which must be strong enough to prevent leakage; but in the latter, the pressure forces the valve against its rubber setting, and so makes its own joint. Opinions differ as to which is the better, but the public seem to like the long lever, as it gives better control when pressing. The sudden spirt when starting a new syphon is due to the valve sticking and coming away suddenly. The Idris



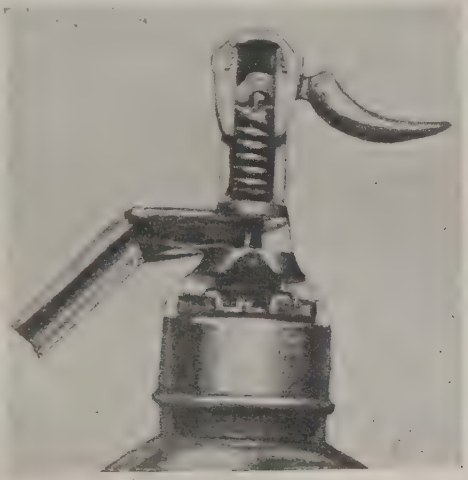
10. SYRUP COOLERS AND FILTERS

Company make a china plug and nozzle fitted inside, so that none of the liquid comes in contact with the metal top. Metal contamination results from the use of unsuitable metal tops.

The Preparation of Syrups. The best crystallised cane sugar is boiled in a steam-jacketed copper. The strength of the syrup is made up to from 40° to 50° Tw., 2 cwt. of sugar being used at each boiling. The syrup is then run into a cooler [10], and fruit acid essences are added to give it the necessary flavours. The mixture is then filtered through a bag to the tank, whence it is led to the various filling machines.

Soda-water varies in strength between 5 gr. and 30 gr. of bicarbonate per pint. The British Pharmacopœia formerly gave soda-water at 30 gr. per pint. Prosecutions are usually instituted where the amount is under 5 gr. per pint. The strength is largely a matter of taste. The amount in the case of lithia is 10 gr., according to the British Pharmacopœia, 1914. Potash is 5 gr. to 15 gr Seltzer water, properly prepared, is a mixture of sodium bicarbonate, sodium chloride, and magnesia, but, as generally sold, means nothing. There are, in addition, aerated distilled water and carbonated water.

Preparation of Ginger-beer. The water is first boiled in a steam-jacketed copper, and is then passed into a mash-tun, where it is mixed with crushed Jamaica ginger. The whole is then run into a settling tank where fruit acids are added, and the liquid, after reduction to proper temperature, is drawn off into the fermenting vat, where it is mixed with sugar (1 lb. per gallon), and allowed to ferment for twelve hours. It is then run off and filled into stone bottles in special filling machines, after which it is stored for about a fortnight, during which time the proper aeration is promoted as a result of the fermentation which takes place. Ginger-beer so prepared contains from 0·6 per cent. to 1·4 per cent. of alcohol. The extreme legal limit is 3 per cent., but manufacturers are warned if 2 per cent. is exceeded.



11. CAMWAL SYPHON TOP

Preparation of Carbonic Acid Gas. Many firms still make their own carbonic acid gas by adding sulphuric acid to whiting or sodium bicarbonate. To a large cylindrical tank, half full of water, a charge of 2 cwt. of bicarbonate is added. Sulphuric acid is then run into it from a reservoir situated at the top, and carbonic acid gas, so called, is drawn off by a pump to the aerating machine. On its passage it is purified free from nitrates by passing through alkaline potassium permanganate solution, which also removes any spray of sulphuric acid which might be carried over mechanically. This method of producing carbon dioxide gives trouble on account of the amount of air it is liable to contain, hence the use of pure natural gas.

Large quantities of sulphuric acid, in jars, surrounded with whiting, are shipped to India and the Colonies for the production of carbon dioxide to be used in the manufacture of aerated waters. If these jars should break during shipment the acid is absorbed by merely converting the whiting into plaster of Paris. The empty jars are cleansed, refilled with Indian pickles, and shipped back to this country. Carbon dioxide is also produced during the process of fermentation in breweries, where it is compressed into cylinders and sold to makers of mineral waters.

Perhaps the most advanced method of producing the gas is from coke, according to Stead's and Leslie's patents. A very ingenious process (Stead's patent) has been installed by the Idris Company, whereby gas of the highest degree of purity is produced. The process consists in the main as follows: The products of combustion of special coal or coke are forced, under pressure of 20 lb. to 30 lb. per square inch, into carbonate of potash solution, which is thereby converted into bicarbonate, after which it is heated with the evolution of pure carbon dioxide, and the re-formation of ordinary carbonate.

Domestic and Automatic Aeration. Retailers of mineral waters can now prepare their own if they so choose. Attempts have been made from time to time to introduce a machine for this purpose. From the description already given of the manufacture of "minerals" on a large scale, the principle of the ingenious "multum in parvo" machine known as the "Consol" (Consol Automatic Aerators, Ltd.) will be grasped readily [13].

It enables the retailer to deliver at the point of consumption an aerated water of good quality, freshly made for each customer, and also enables him to dispense with the cumbrous boxes of bottles formerly needed for his business.

This machine occupies a space only slightly exceeding 1 sq. ft., and can be fitted to any bar or shop counter. In addition to ordinary aerated water, it can be made to produce soda, potash, lithia, lemonade, ginger-beer, ginger-ale, etc., by adding the necessary amount of soluble constituents, according to well-known recipes.

It differs from other "draught apparatus," such as soda fountains, various forms of draught arms, etc., in that it manufactures each drink as required, whereas ordinary apparatus has to draw from a previously manufactured store, which deteriorates on keeping. The entire operation is performed by a right and left movement of the handle, which occupies a period of not more than five seconds, so that it is possible to draw on draught the equivalent of 60 dozen bottles per hour.

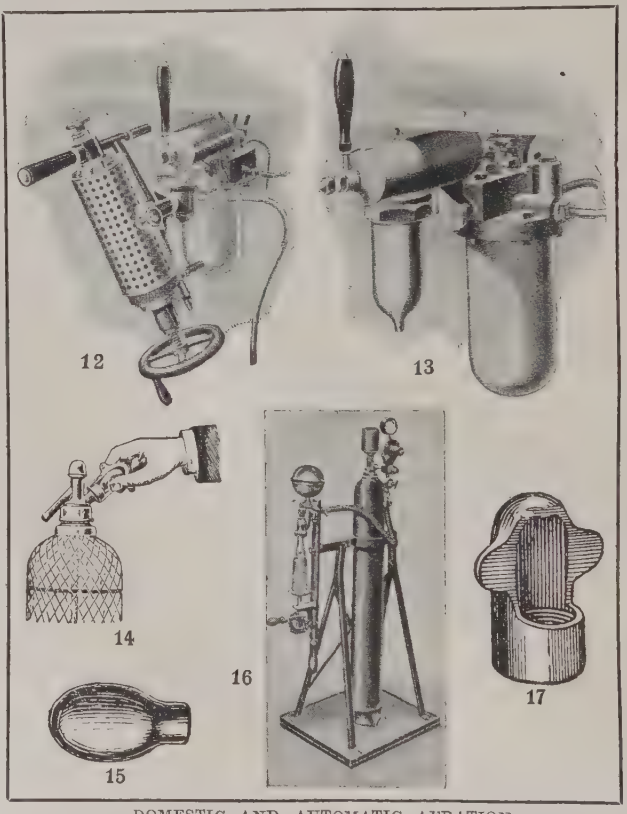
A filter should always be fitted where any doubt exists as to the purity of the water, and in all cases where it is desired to produce the highest class of "minerals." Suitable germ-proof filters have been designed for special use with the aerator, all that is necessary being to introduce the filter at any convenient point in the water supply.

Aerated Water in Open Jugs. It is claimed by some that aeration on a small scale produces a different result to aeration in bulk. It is

said that it so saturates the water with the gas (CO_2), that it is actually held in solution, and not given off in a violent eruption upon the removal of outside pressure. The experiment described below may be taken as showing that water aerated in bulk does *not* retain the gas for any length of time after opening the bottles. We cannot undertake to sift the evidence on this point, and as "minerals" from bottles and syphons, especially the latter, are consumed almost immediately after opening, we need hardly concern ourselves with it. Nevertheless, domestic aeration makes it possible for aerated water to be served in open jugs, without detriment to its sparkling qualities, a point which should prove of decided gain to the public.

The following simple experiment illustrates this. A tumbler of aerated water is drawn from the small hand machine, and a similar tumbler is filled from a bottle or syphon supplied from an ordinary mineral water factory. The two are left side by side for half an hour or longer; each is then gently stirred with a thin rod or knitting needle. That from the bottle will be comparatively flat, whereas that from the small machine will "bead" round the rod and effervesce freely.

Although the aerator has been designed primarily to make and supply aerated water straight into the glass, yet both screw-stoppered and corked bottles can be easily and rapidly filled. Where it is desired to bottle under pressure, an attachment is added for filling any description of bottle, particularly suited for ball-stoppered bottles (known in the trade as cod bottles). This is attached to the aerator by removing the delivery vessel. The illustration [12] shows the attachment.



DOMESTIC AND AUTOMATIC AERATION

12. Consol aerator for bottles 13. Consol aerator for counter supply
14. Sparklet syphon top 15. Sparklet gas bulb 16. Mineral water bottle filler (H. Toomer & Co., Ltd.) 17. Sparklet bulb-holder

Another Simple Machine for Bottling Only. Another machine, worked somewhat differently, is shown in 16. In this case the bottles have first to be filled with the water to be aerated. They are then clamped on to the attachment communicating with a tin ball full of gas under pressure. By pulling up the lever, the bottle is inverted, causing the water to flow into the ball, where, by the aid of shaking, it becomes aerated. The lever is then lowered, so that the bottle is the right way up, when the aerated water finds its way back into the bottle. The machine is of cheaper construction, but slower in its action than the "Consol," and it will not deliver direct into the glass. It appears to answer its purpose.

Sparklet Aeration. We will conclude our account of mineral waters with a short description of the Sparklet syphon (Aerators, Ltd.). By means of this ingenious system anybody can make at any time and in any place as much freshly aerated water as desired. The principle of the system consists in the sale of carbonic acid gas strongly compressed in small steel bulbs which are fitted on to the syphon and pierced by turning a screw, which allows the gas to escape and saturate the water with which the syphon is previously filled. The bulb containing the carbonic acid gas, and the bulb-holder into which it is slipped neck downwards, are shown in 15 and 17. The vase of the syphon, the upper part of which is shown in 14, is filled with water to a red mark near the top, the glass tube is inserted, and the head screwed down without employing undue force. The bulb-holder, containing the bulb, is held with the thumb on the bulb so that the neck of the latter protrudes slightly below the bottom of the holder. The protruding neck of the bulb is now inserted centrally into the hollow formed by a washer and gently screwed down. Inside this hollow and projecting outward is a pin, which enters the end of the bulb and pierces it, in this way admitting the gas from the bulb into the syphon. The bulb-holder is screwed down gradually, shaking the syphon well from time to time and continuing alternate screwing and shaking until no more bubbles of gas are given off. The syphon is now ready for use, but the aeration is improved if the syphon be allowed to stand a few minutes before drawing off the contents.

The glass vases are covered with a metal wire, and are tested to a pressure of 220 lb. per square inch.

Either plain water alone can be aerated or small quantities of soda, potash, lithia, or fruit crystals may be previously added in the form of "sparkloids," thus producing soda, potash, or lithia water, or other effervescing drinks of various descriptions.

CLAYTON BEADLE and H. P. STEVENS

FOOD SUPPLY CONCLUDED—END OF GROUP 18

Petroleum Oil and its By-products. Shale Oil. Uses of Petroleum and its Products.

REFINING PETROLEUM

THE object of the operations which are collectively known as the refining of crude petroleum is to separate the liquid into a series of products best suited for various industrial uses. Crude petroleum as it comes from the well has already been shown to consist chiefly of a mixture of hydrocarbons or chemical compounds of the two elements hydrogen and carbon. These hydrocarbons exhibit a progressive range of boiling points, those at one end of the scale boiling at common temperatures, whilst those at the other end require to be heated to many hundred degrees Fahrenheit before entering into ebullition.

Fractional Distillation. It is, therefore, obvious that if we apply a gradually increasing heat to the crude petroleum we shall successively convert one constituent after another into vapour in the order of their boiling points, and if we pass this vapour through a tube surrounded by cold water we shall cause it to return to the liquid condition. The liquid so obtained may evidently be collected in as many separate portions as we wish, and we have thus the means of dividing and subdividing the crude oil into various products. The process in question is termed *fractional distillation*, and the separated liquids or distillates are called *fractions*.

Stills and Condensers. On the practical working scale the fractional distillation is carried out by the use of a still and a condenser. The still usually consists of a horizontal cylindrical vessel of iron or steel plate, with a dome, like that of a steam boiler, from which a tube or vapour-pipe passes with a slight downward inclination to the condenser. The still is set in brickwork, and is heated by a furnace. The condenser commonly consists of a coil of iron tubing, or a series of straight pipes joined by curved pipes or bends, placed in a tank filled with cold water. The outlet end of the condenser passes into a trough arranged so that the stream of liquid issuing from the condenser may be diverted into various receptacles.

Products. When ordinary crude petroleum is heated in such a still the first commercial product which flows from the condenser is petroleum spirit, or benzine, and this is allowed to flow into the tank provided for it until the temperature of the contents of the still has risen to such a point that distillation of the next commercial product—namely, the petroleum oil or kerosene, for use in lamps—begins. The stream of distillate is then diverted into the kerosene tank until the whole of this product has been obtained.

On further increase of temperature oils of higher boiling point, intermediate in character between the kerosene and the lubricating oils, distil over, and, lastly, lubricating oils of various grades issue from the condenser, these containing the solid paraffin wax if the crude oil undergoing distillation contains this substance, the residue in the still consisting of coke if the distillation is carried to *dryness*, as it is termed.

Usually the process herein described is conducted in two parts, the benzine and kerosene being separated in one still, and the distillation being completed in another still to which the residual oil is transferred. In some districts, and notably in Russia, only a small proportion of the residue which remains after taking off the benzine and kerosene is further distilled, the greater part of the residue being sold as liquid fuel. Where the distillation is carried to dryness, the operation is completed in cast-iron stills, the bottoms of which are of hemispherical form. In the distillation of the lubricating oils it is customary to inject steam into the stills, as this tends to prevent the products being injured by overheating, and facilitates the passage of vapour from the still to the condenser. On the other hand, in the distillation of the kerosene, overheating is often aimed at, the yield being thus increased by what is known as "cracking," which is the conversion of some of the heavier constituents of the crude oil into lighter ones of lower boiling point.

The benzine distillate is re-distilled with the aid of steam, so as to subdivide it into the various commercial products, including motor spirit.

Continuous System of Distillation. The process of fractional distillation which has been described is known as the *intermittent* system, because the still has to be periodically re-charged. In conducting the process of *continuous* distillation, which is the system commonly adopted in Russia, a series of stills is employed. The second of the stills in this series is heated to, and maintained at, a higher temperature than the first, the third to a higher temperature than the second, and so on throughout the series of ten or a dozen, or even more, stills. The crude oil is caused to flow slowly through the whole series, being thus subjected to a gradually increasing heat, while the temperature of the contents of each still remains practically constant. Under these conditions each still continuously yields a product of given boiling point corresponding with the temperature at which it is maintained, and the loss of time, waste of fuel, and injury to plant involved in cooling down and re-heating the stills in the intermittent system are avoided.

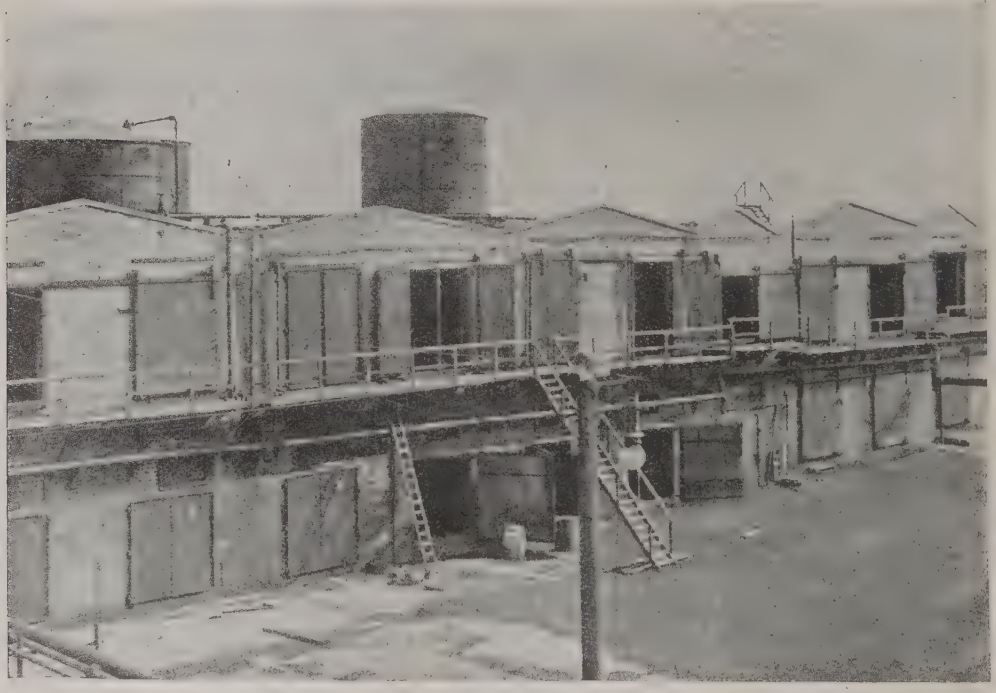
Benzine and Kerosene. The benzine or benzine products and kerosene are purified by agitation successively with sulphuric acid and a solution of caustic soda, followed by washing with water, and when the crude oil contains sulphur a special process is also adopted to remove this impurity from the distillates. The agitation is effected by means of compressed air, the operation being conducted in vertical cylindrical iron vessels termed agitators.

Lubricating Oils and Solid Paraffin. The lubricating oil distillates obtained from crude petroleum containing solid paraffin are artificially cooled to a low temperature, when the paraffin crystallises out and is separated from the oil by means of filter presses and hydraulic presses. The paraffin thus obtained is cast into thin cakes, which are slowly heated in an oven, when the most fusible or readily melted part liquefies and runs

away, carrying impurities with it. The residual wax is then melted up and refined by means of animal charcoal or fullers' earth, being thus rendered colourless and odourless. The separated lubricating oils of various grades are purified in the same manner as the kerosene by treatment with acid and alkali.

Vaseline. This product is obtained by concentrating the residuum of ordinary Pennsylvanian or other similar petroleum to the consistency of butter, and dissolving it in petroleum spirit, the solvent being evaporated off after repeated treatment of the solution with animal charcoal.

Characters of the Commercial Products. On redistillation, benzine obtained from the crude petroleum of the United States may be divided into gasoline and a number of other less volatile products, but gasoline itself is sometimes further subdivided into cymogene, rhigolene, and gasoline. Cymogene boils at 32° F., and can therefore be preserved only in a liquid state in a freezing mixture, or under pressure, while rhigolene has a boiling-point of 65° F. These products, which have in admixture a specific gravity of ·636, have been used for surgical purposes as local anæsthetics. A highly volatile product, of specific gravity ·625, obtained from gasoline, has also been employed for the same purpose in admixture with sulphuric ether. The generic term of *petroleum ether* is applied to the product in question (not the mixture), but various other descriptions of petroleum ether of higher specific gravity and lower volatility (or higher boiling-point) are made in this country. Gasoline, the specific gravity of which formerly ranged from ·642 to ·648, is used to carburet air in what are known as *air-gas machines*, for burning as an illuminant, and is also largely employed as fuel in cooking-stoves in the United States. The term "gasoline" is now commonly applied in the United States to any description of motor spirit. For use in the internal-combustion engines of motor-cars, preference was formerly given to a petroleum spirit of ·680 specific gravity imported from the United States or manufactured in this country, but it has become difficult to obtain adequate supplies of this product, and within recent years there has been a progressive increase in the specific gravity of the spirit employed for the purpose. Moreover, a large proportion of the benzine now imported comes from the Dutch East Indies, and this product has a lower boiling-point in relation to the specific gravity than that of the American spirit, so that the specific gravity has ceased to be a trustworthy guide to the volatility of the product unless the origin of the spirit is also taken into account. Petroleum spirit from Rumanian petroleum is also now an article of commerce in this country.



1. SWEATING-STOVES FOR THE PURIFICATION OF PARAFFIN WAX MADE FROM SHALE OIL

Refined Oil. The refined oil (kerosene) obtained from the crude petroleum of the United States is of several descriptions, but only two of these—the ordinary American lamp-oil of commerce, known under the brands of Tea Rose, Royal Daylight, etc., and water-white or high-test oils, sold under the brands of White Rose, Snowflake, etc.—are imported into this country. The ordinary oil is usually of a pale straw colour, and has a specific gravity of about ·800. Its flash-point is generally not much above the legal limit of 73° F. (Abel test). The higher grade of oil, of which the average crude petroleum yields only about 15 per cent. or 16 per cent., is colourless, or nearly so, and has a specific gravity of about ·79. Its flash-point is over 100° F. (Abel test). There is also manufactured to a small extent a burning oil having a specific gravity of ·825 to ·830 and a flash-point of about 250° F.

(Abel test). Of this oil, which is usually known as *mineral colza oil*, about 10 per cent. may be obtained from the crude petroleum.

Russian crude petroleum furnishes parallel products of a somewhat different character. The yield of benzine is usually much lower, and the ordinary kerosene, obtained to the extent of only from 27 per cent. to 40 per cent, of the crude oil, has the comparatively high specific gravity of ·825, and a flash-point of about 85° F. (Abel test). The most important commercial product is the residuum, which, under the name of *ostatki*, is very largely employed as liquid fuel.

Kerosene is also imported into Great Britain from Rumania.

Of mineral oils for lubricating purposes an extensive series is imported from the United States and Russia under the names of spindle oil, engine oil, cylinder oil, valve oil, etc., the names indicating the general characters and uses. These oils are of various specific gravities, flash-points, and viscosities, according to the purposes for which they are intended.

Oils for gas-making and other purposes, intermediate in physical characters between the burning oils and the lubricating oils, are also imported.

Methods of Testing. Although, for commercial purposes, many tests are applied to petroleum products in order to ascertain their suitability for the uses to which they are intended to be put, the legal enactments are based solely on the determination of the risk of fire as measured by the temperature at which inflammable vapour is given off by the oil, the test being known as that of *flashing-point* or *flash-point*, and on this basis regulations are made respecting the keeping, carriage, and handling of such crude oils and products as are regarded as dangerous. The early petroleum legislation in the United Kingdom fixed the standard of flash-point at 100° F., the test being performed by heating a sample of the oil in a small open cup placed in a water-bath, the arrangement resembling a carpenter's gluepot, and passing a small flame at intervals across the surface of the oil as the temperature rose above 90° F., until a pale blue flicker or flash was observed.

The Abel Test for Flash-point. Owing to the unsatisfactory results furnished by this comparatively rough method of testing, the Petroleum Act of 1879 was passed, with the object of substituting the "Abel test," devised by the late Sir Frederick Abel, in which a closed cup is used. The Abel testing instrument consists of a cylindrical oil-vessel, fitted with a thermometer and provided with a cover, in which there are three openings. These openings are covered and uncovered by means of a slide working in guides, and having corresponding perforations. As the slide is drawn back to open the cup, it automatically tilts a small test-lamp, so that the flame of the latter just enters the oil-vessel. The oil-cup is placed in an air-jacketed space in an outer vessel containing water previously heated, and, in order to ensure uniform results, the test has to be performed in accordance with specific directions relating to the filling of the oil-cup, the initial temperature of the water-bath, the size of the test flame, and the time occupied in applying this flame. The first application of the flame is made when the oil attains a temperature of 66° F., and the standard flashing-point is fixed at 73° F., this temperature corresponding to the old standard of 100° F. in the open cup. A modification of this apparatus, in which the slide

This photograph and that on the opposite page are reproduced by courtesy of the Pumpherston Oil Company, Glasgow

is moved by clockwork, is used for testing petroleum under the Indian Petroleum Act, the minimum flashing-point for safe oil being fixed at 76° F., with a correction for the effect of variations in atmospheric pressure. In India the application of the test flame is directed to be begun at a relatively earlier stage of the test than in colder countries, with the object of getting rid of the vapour which is liable to be disengaged from the oil in filling the cup in a tropical climate, as this may cause a flash to occur prematurely.

Testing Lubricating Oils. For testing the flash-point of lubricating oils, another modification of the Abel apparatus, known as the Pensky-Martens tester, is largely used. The oil-cup of this instrument is fitted with a stirrer to ensure uniformity in the temperature of the contents of the cup, and the application of the test flame (furnished by coal-gas issuing from a small jet) is effected by means of a rotating vertical rod. The oil-cup is heated to the requisite temperature in a cast-iron air bath surrounded by a brass jacket.

The viscosity of lubricating oils is also tested, for this affords a measure of the relative lubricating values of the oils. The instruments employed in making this test are termed *viscometers*, and their action is usually based upon the principle of determining the time occupied in the outflow of a specified quantity of the oil through a jet or small orifice at a given temperature. The standard instrument in this country is the Redwood viscometer, while on the European continent a somewhat similar form of apparatus, known as the Engler viscometer, is largely used.

The commercial value of paraffin wax is largely governed by the so-called *melting point* (which is really the setting point or solidifying point) of the material. This is determined by melting a small quantity in a test tube and stirring it with a sensitive thermometer while the tube and its contents are allowed to cool slowly in the air until a point is reached at which the cooling is arrested by the heat given out by the solidifying paraffin, and the mercurial column remains stationary for a short time. The temperature recorded by the thermometer when this occurs is the melting point.

Transport. Refined oil (kerosene) is chiefly transported in bulk in tank steamships, tank barges, tank railway waggons, similar to those already referred to as being employed in the carriage of crude petroleum, and tank road waggons, the aim of modern practice being to cheapen the cost of transport by keeping the oil in bulk from the time it leaves the refinery until it reaches the lamp in which it is burned. The use of the 40-gallon wooden barrels in which this product was at one time so largely distributed has, accordingly, been almost entirely superseded, but "cases," which are wooden boxes, each holding two tin cans of 4-gal. capacity, are still largely employed for sending the oil into sparsely populated countries, especially in the tropics.

At the present time the Atlantic petroleum steamship fleet is a large one, and some of the vessels are of great capacity. The engines and boilers are sometimes placed amidships and sometimes at the after end. The tanks are formed by the skin of the ship, a decking, and a series of transverse bulkheads, with a central fore-and-aft bulkhead, and they are isolated from the stokehold and engine-room by a double bulkhead or coffer-dam, two of these being required when the engines are amidships, and the screw-shaft being then carried through an oil-tight tunnel. The most important fundamental principle of construction lies in the provision of expansion trunks, extending upwards from the top of the tanks, by means of which the contraction and expansion of the oil under changes of temperature are allowed for, and the tanks always remain full. If it were not for this arrangement the tanks would be liable to overflow or to become partially empty, when the oil would be liable to be set in oscillation and the safety of the ship would be imperilled. The oil is delivered into these steamships by pipe-lines, and is discharged at the rate of hundreds of tons per hour by the vessel's powerful pumps.

Lubricating oils are now very largely shipped from the United States in bulk, and wholly so from Russia. The gas-oil used by gas companies in the manufacture of carburetted water-gas, and in the enriching of coal-gas, is also shipped in bulk.

Paraffin scale for candle-making is transported in barrels, the material being frequently run into the packages in a melted state; and paraffin wax is packed in cases.

Under the bylaws of the Thames Conservancy, petroleum spirit, now almost entirely imported in bulk, is landed at Thames Haven, and is brought up the river in licensed tank barges.

Scottish and Other Oil Shales. The bituminous shales occurring in Scotland (Linlithgow and Midlothian), France (Autun), New South Wales, New Zealand, Nova Scotia, Serbia, and elsewhere, yield on destructive distillation, besides ammonia, a series of commercial products, including burning oil, lubricating oils, and solid paraffin, resembling those obtained from crude petroleum. The Scottish shales usually give from 18 gal. to 30 gal. of crude oil to the ton, and in some cases as much as 60 lb. to 70 lb. of sulphate of ammonia. A rich description of shale is mined in New South Wales, which furnishes over 100 gal. of oil to the ton, and some of the New Zealand shale is remarkable for the very large proportion of solid paraffin obtainable from the products of distillation.

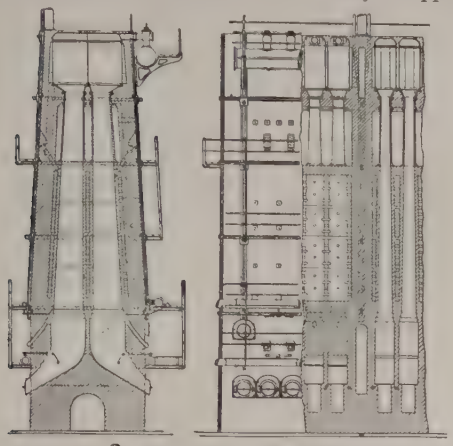
Scottish Shale Oil Industry. The industry has suffered severely from the competition of imported petroleum products, but adversity has been met in a manner deserving of the highest praise, remarkable improvements in plant having been made, and economics effected in working costs. In this connection it should be pointed out that in distilling shale there is an additional source of profit in the ammonia obtained with the oil, and that of the most valuable of the oil products —namely, the solid paraffin—shale oil usually gives a comparatively large yield.

Oil shale is mined similarly to coal, is screened at the mine, and on reaching the works is broken by machinery into flat pieces about six inches square.

Shale Retorts. Horizontal retorts, similar to those used in coal-gas manufacture, were at first adopted for the distillation of the shale, but at an early date these were replaced by vertical retorts, and steam was injected into the retorts to carry off the oil vapours. Distillation under reduced pressure was subsequently introduced, and the spent shale was utilised as fuel for heating the retorts. The use of steam increased the yield of oil by 20 per cent., and by subjecting the shale to a higher temperature in the presence of steam after the oil had been driven off at a moderate heat, a much larger proportion of the nitrogen was obtained in the form of ammonia.

Various improvements in shale retorts were made from time to time by Young, Henderson, Beilby, Fyfe, and others, with the objects of diminishing the cost of working and increasing the yield of oil

and ammonia. The retorts at present in use, of which one type is shown in 3, hold about 30 cwt. and are about 28 ft. in height; they consist of an upper portion of cast iron, surmounted by a hopper,



3. SHALE OIL RETORTS

and a lower portion of firebrick. They are set in benches in a combustion chamber, and are heated through the agency of a gas-producer. The upper part is heated to dull redness, and the lower to a bright, red heat.

Retorting. The process of distillation is a continuous one, the spent shale being gradually withdrawn from the base of the retort, and a corresponding quantity of fresh shale entering from the hopper at the top. About twenty-four hours is occupied in the passage of the shale through the retort.

The vapours issuing from the distilling charge, amounting to about 3,000 cubic ft. per ton of shale, pass from the top of the retort into a vertical tube condenser, where the oil and ammoniacal liquor are separated. The uncondensed gas may be used for lighting or heating, or the very volatile liquid hydrocarbons which it contains may be obtained by passing it through a scrubber, and the residual gas, which then has no illuminating power, is utilised as fuel.

The ammoniacal liquor from the condenser is distilled, and the liberated ammonia is brought into contact with sulphuric acid, with which it combines to form commercial sulphate of ammonia.

Shale Oil Refining. The crude shale oil, which is of a dark green colour, is subjected to a continuous process of fractional distillation substantially similar to that already described as applied to crude petroleum, and is thus separated into light and heavy oils and paraffin wax, steam being passed into the stills in order to facilitate the operation and prevent injury to the products by overheating. The light oil furnishes a small proportion of naphtha on redistillation, after treatment with acid and alkali, the remainder of the light oil consisting of the burning oil, or paraffin oil, used in lamps. The heavy oil is cooled, so as to cause the solid hydrocarbons to crystallise out, and is then passed through filter-presses, which separate the paraffin from the oil.

Paraffin Refining. The crude paraffin was formerly refined by dissolving it in the naphtha obtained from the light oil distillate, allowing it to crystallise out in shallow trays, and pressing the cakes thus obtained. This method of treatment has, however, been superseded by the "sweating" process, in which the paraffin is pumped, in a melted state, into shallow trays, supported above transverse heating-pipes in a closed chamber or stove. Each tray is fitted with a perforated strainer, of about 16 apertures to the inch, which is covered to the depth of about half an inch with cold water, the melted paraffin floating on this layer of water above the strainer. When the paraffin has solidified, the water is drawn off, and the cake of paraffin rests on the strainer. Steam is then passed through the heating-pipes, and the temperature of the stove is slowly and cautiously raised to the point at which sweating takes place. The effect of the heat so applied is to cause the softer and more fusible portion of the paraffin to melt and drain through the strainer, carrying with it the impurities, and this portion is drawn off. The hard paraffin remaining on the strainer is then melted by further raising the temperature of the stove, drawn off from the tray, decolorised by agitation for some time with animal charcoal and cast into cakes for sale to the candle makers.

Yield of Products. The heavy oil from which the paraffin has been separated in the filter presses yields, by further refining, a series of lubricating oils of various specific gravities, flash-points, and viscosities. The proportions of the various commercial products yielded by Scottish shale vary with the nature of the shale and the process of manufacture, but may be taken as ordinarily being about 3 per cent. to 6 per cent. of naphtha (including gasoline), 39 per cent. of burning oil (including gas oil), 18 per cent. of lubricating oils, and 10 per cent. of paraffin (refined and semi-refined), the loss being thus no less than 30 per cent. The loss is very large compared with that sustained in the refining of crude petroleum, and indicates the disadvantage under which the shale-oil refiner works. Before he is in the same position as the petroleum refiner he has to mine and break the shale and subject it to destructive distillation, and his crude oil is far more difficult to refine than the raw material with which the petroleum refiner usually has to deal. Against the extra expenditure which this entails the profit on the sulphate of ammonia is to be set, and it is this, coupled with the large yield of the valuable product, paraffin, which has enabled the shale-oil industry effectively to meet the competition of petroleum.

French Shale Oil Industry. In France the distillation of shale was begun as far back as 1830, and the French industry is, therefore, much older than the Scottish, though it has made less progress, and is of smaller commercial importance. The chief centres of the industry are at Autun, and Buxière-les-Mines. The shale yields only about 17¼ gal. of oil to the ton, and 5 per cent. to 7 per cent. of sulphate of ammonia. The oil is fractionated and refined in the same manner as Scottish shale oil, but is less easily converted into commercial products of satisfactory quality. It yields about 3·5 per cent. of naphtha, 19 per cent. of burning oil, 23 per cent. of gas oil, 8 per cent. of pale oil, 17 per cent. to 18 per cent. of lubricating oils, and 2·7 per cent. of refined paraffin. The industry has declined since the removal of the heavy import duties on crude petroleum, which formerly protected it.

Australian and New Zealand Shale Oil. In New South Wales, a so-called "kerosene shale," resembling cannel coal, has been mined and distilled since 1865. Some of this mineral yields over 100 gal of oil to the ton. The retorting has latterly been carried on near Torbane, west of the Blue Mountains, and about 130 miles from Sydney,

the crude oil being transported by rail in tank waggons to a refinery at Hartley Vale. A few years ago an English company was formed to develop the industry on a large scale.

Bituminous shales occur in the upper portions of the coal measures of New Zealand, and that which is found at Orepuki yields a crude oil containing a remarkably large proportion of solid hydrocarbons.

The Brown Coal-tar Industry. In Prussian Saxony, the destructive distillation of lignite, and conversion of the tar obtained into commercial products resembling those yielded by shale oil, constitutes an industry of local importance. The tar is fractionally distilled under reduced pressure, with the object of preventing the decomposition which would otherwise occur, and in this manner from 8 per cent. to 30 per cent. of light oil, 15 per cent. to 30 per cent. of lubricating oils, and 1·5 per cent. to 12 per cent. of paraffin, are made from it. In other respects the process adopted resembles that already described as applied in the refining of shale oil.

Kimmeridge Shale. The extensive deposits of shale in Dorsetshire admit of being mined at a low cost, and give a satisfactory yield of crude oil, but the refining of this oil presents exceptional difficulties which have hitherto stood in the way of its utilisation.

Uses of Petroleum. Crude petroleum has from the earliest times been employed as a curative agent, especially in cutaneous affections of men and animals, in the treatment of wounds, and for the relief of strains and rheumatism. For pharmaceutical purposes crude petroleum is no longer in general use by civilised communities, but the well-known product vaseline is very largely employed, both alone, and as a means of applying medicinal substances, where local action, rather than absorption, is desired, its physical and chemical characters rendering it superior to an animal fat for such a purpose.

Vaseline is also largely used as a protective coating for surfaces liable to injury from damp and exposure to the air; and it is an important ingredient of the smokeless explosive, cordite.

In surgery the more volatile products of petroleum have been found valuable as anæsthetics, especially in producing local insensibility by the cold resulting from rapid evaporation.

Petroleum Lighting and Heating. As a source of light and heat, petroleum and natural gas have been favourably known for ages, and at the beginning of the second half of the past century the petroleum or paraffin lamp and the paraffin candle became recognised as among the necessaries of civilised life. Indeed, it may be said that no modern article of commerce has done as much as refined petroleum to promote comfort and extend man's capacity for leading a fruitful life, for it has encouraged domesticity and has largely increased the number of hours available for study. Recognising this, some have even gone as far as to say that the progress of a nation in civilisation may be measured by the consumption of petroleum per head of population.

The illuminating agent supplied by the gas companies is often largely composed of carburetted water-gas, in the manufacture of which great quantities of petroleum are used. In some of the principal cities of the United States the latter gas has, in fact, entirely replaced coal-gas. Volatile petroleum products are also used in enriching coal-gas, so as to bring its illuminating power up to the required standard.

Petroleum-driven Vehicles. It is scarcely necessary to mention the highly important part which petroleum spirit is now playing in providing the means of locomotion through the medium of public service vehicles (motor omnibuses) in the great cities, and private self-propelled carriages throughout the country.

The advent of the private motor-car has directed renewed attention to the splendid high-roads of this country, and has revived the ancient glories of wayside hostelries, with great advantage to the mental and physical condition of those who are able to employ, temperately, this means of travelling.

It is well known that the source of power in that modern addition to the belligerent marine, the submarine, is petroleum, these vessels being propelled by internal-combustion motors while on the surface of the water, and receiving their stores of the electricity which drives them beneath the surface from the same source.

As liquid fuel for use in steam raising for power purposes, both on land and at sea, as well as in metallurgical and other work, petroleum has now taken a most important place as a heating agent of far higher efficiency than even the best steam coal, but the steam-engine is now being largely replaced by internal-combustion engines of the Diesel type, which furnish a much more economical source of power.

Lubricating Oils. The lubricating properties of petroleum were recognised at a very early date, and one of the first applications of the more viscous descriptions of this product found on or near the surface of the ground was in the greasing of the wooden axles of primitive carts. The manufacture of lubricating oils from petroleum has long since been brought to a high degree of excellence, and such oils have now very largely replaced the animal and vegetable oils and fats previously employed for the purpose.

There is a large consumption of the softer and more fusible kinds of paraffin for rendering wooden matches readily inflammable. Paraffin also is or has been used in waterproofing match-heads; in strengthening and waterproofing woollen fabrics; as a "resist" in dyeing, the parts of the fabric coated with it rejecting the dye; for lining brewers' vats and beer barrels; for preserving stone, wood, eggs, meat, fruit, and flowers; for glazing, protecting, and waterproofing paper; as an adjunct to starch for glazing linen; as an auxiliary to soap for laundry work; as an electrical insulator; as a substitute for fat for absorbing perfume from flower petals; and as an easily-moulded material in making ship models.

Petroleum in Soap Manufacture. The detergent properties of petroleum account for its extensive introduction into household soaps. Petroleum is also the active ingredient of certain insecticides. Petroleum spirit is largely employed in the process known as dry-cleaning; in the extraction of grease from leather; as a solvent for various purposes, and especially, in a carefully prepared form, as a substitute for oil of turpentine for use in making paints and varnishes.

Among other uses of petroleum may be mentioned those of ore-concentration, and the removal of fusel oil from crude molasses spirit.

In the form of "westrumite," and other preparations, petroleum has been successfully employed as a dressing for road surfaces to prevent disintegration and the raising of dust, its slower rate of evaporation rendering its action more lasting than that of water.

Many patents have been granted for the solidification of petroleum, chiefly with a view to the use of the product as a fuel, either alone, or in admixture with coal-dust or other combustible substances, in the form of briquettes. Among the solidifying agents which have been specified for this use are resin soap, extract of quillaia bark, lichen extract, fish glue, casein, and glue (with formalin as a hardening agent).

A product known as soluble petroleum is prepared by partially saponifying resin previously dissolved in the oil, or by blowing air through a mixture of resin oil and caustic soda solution, and adding to the jelly-like mass thus obtained an aqueous solution of a fatty oil soap and mineral lubricating oil. The product is intended to be employed, in admixture with water, as a lubricant, especially for tools used in boring and cutting metals, and is stated to have given excellent results.

Petroleum as an Illuminating Agent. Petroleum or paraffin lamps are usually fitted either with a single or duplex flat-wick burner or with an Argand burner, the former being more largely used in Great Britain and America, while the Argand, or annular wick type, is more popular on the Continent. The latter type of lamp is provided with a central air-supply channel, sometimes extending down through the oil-container to the base, and a disc or button is usually fixed at a short distance above the top of the wick-tube, so that the upward current of air induced by the heated chimney is deflected outwards and caused to impinge on the inner surface of the flame. Air is also supplied separately to the outer surface. Burners of the duplex type are usually fitted with an extinguisher, which is sometimes arranged to come into action automatically in the event of the lamp being overturned.

In one form of lamp the petroleum is vaporised and the vapour is conducted into an inverted Argand burner; in another a mixture of petroleum vapour and air, burning with a non-luminous flame, is employed to heat a Welsbach incandescent mantle.

A given amount of light was formerly obtainable from mineral oil at a much lower cost than from gas, but the general use of the incandescent mantle has so largely added to the efficiency of the latter illuminating agent that the comparative positions in respect of cost have been reversed, unless a mantle be also used with oil.

Petroleum Lamps. The subject of accidents with mineral oil lamps has in past years attracted considerable attention, and it has been contended that the minimum legal flash-point of 73° F. should be raised to 100° F. in the interest of public safety.

Formerly all lamp accidents were described in the newspapers as explosions, but investigation has shown that at least 75 per cent. or 80 per cent. of them have been due to the overturning or dropping of the lamp or to its fracture from some other cause. In fact, with a properly constructed lamp, and with ordinary care and intelligence in its use, an explosion ought never to occur.

In choosing a table lamp the purchaser should note whether it has sufficient stability, or, in other words, whether it is easily upset or not. If the lamp has the usual pedestal its attachment to the oil container should be substantial. The oil container should be of sufficient strength to withstand a fall from the height of a table on to a bare wooden floor without being broken or allowing the oil to escape, and, notwithstanding the merits of glass, it is safer to have a well-made container of metal. The burner should be securely attached to the oil container, and there should be no opening in it by which flame can communicate with the interior of the oil container. The burner should admit of being taken to pieces for cleaning, and it should be fitted with a good, substantial chimney gallery.

The Use of a Lamp. In the care and use of the lamp, the following should be borne in mind:

1. The wick should quite fill the wick-tube without having to be squeezed into it.
2. Before using, the wick should be dried at the fire, and then immediately soaked with oil.
3. Wicks should be in lengths of not more than 10 in., and should always reach the bottom of the oil container.
4. It is well to change the wick after two months' use.
5. See that the chimney of the lamp fits properly, and is held sufficiently tight so as not to fall off when the lamp is used.
6. When a new wick or chimney is required, it is always advisable to take the burner to the shop so that it may be properly fitted.
7. The burner should be taken to pieces and thoroughly cleansed at least once a month, and all burnt pieces of wick, dead flies, etc., should be carefully removed.
8. Never refill the lamp when it is alight or near a fire or other light.
9. After filling, see that the burner is properly fixed on, and if there is a side filling-hole, be careful to screw in the plug.
10. Before lighting, remove the burnt crust of the wick.
11. Be careful not to spill oil in filling, and if any is spilt on the lamp, wipe it off.
12. Before lighting, see that the slit in the cone of the burner is exactly over the wick-tube, so that the flame will not touch the metal.
13. When first lit, the wick should be partially turned down, and then gradually raised, but not so as to smoke. When the edge of the flame is orange coloured the lamp is not burning properly, and the burner should be examined.
14. Do not continue to burn the oil until it is completely exhausted. It is best to keep the lamp well filled.
15. Lamps which have no extinguisher should be put out thus: The wick should be turned down until there is only a small flickering flame, care being taken not to turn down so far that the wick falls into the oil container. The small flame may be extinguished by placing a piece of flat tin or card on the top of the chimney or by blowing across the top of the chimney. Never blow down the chimney.
16. Never use a lamp which is broken or in any way out of order, or a chimney which is cracked. If any part comes loose, or is out of shape or defective, it should be taken to a lamp shop to be repaired.
17. Always place the lamp in a secure place, and on a level surface, and never on a rickety table, or in any position where it could be easily upset. Hanging lamps should not be put on insecure nails in the wall.
18. Table lamps should not be carried about more than is necessary, and nothing else should be carried at the same time. Heavy lamps should be carried in both hands. The greater number of lamp accidents have been caused by dropping a lamp while it was being carried.
19. Lamps should not be turned down except for the purpose of putting them out. If turned low, the oil is liable to be unduly heated.
20. Should a person's clothes become ignited, the flames should be smothered with a hearth-rug, blanket, woollen tablecloth, or wet towel.
21. Never pour oil on a fire.

Outdoor Lighting. Various special kinds of lamps are used in the open air. For use on ships and on the rolling-stock of railways it is necessary that the lamps shall be constructed so that the air supply is not affected by the force of the wind, and that water cannot gain entrance. In the lighting of large areas during building and engineering operations, extensive use is made of lamps of the Lucigen and Wells type, in which the oil is forced up from a closed receiver by compressed air and sprayed through a heated burner, a light of 2,000 to 2,500 candle-power being given. In the Kitson lamp for street lighting compressed air is also used to raise the oil to the burner, where it is vaporised, and by means of the flame thus obtained a large mantle is heated to incandescence. A light of 1,000-candle power is thus produced at the very low cost of 1d. per 1,000 candle-hours. This represents the highest economy hitherto obtained in the use of mineral oil, and compares with 2¼d. for the incandescent table lamp, or 7½d. for the duplex lamp. The same amount of light obtained from coal-gas on the pressure incandescence system (with

which the Kitson system of oil burning is fairly comparable) probably costs, on the average, about 1¾d.; with the ordinary incandescent mantle as used in dwellings, 2¼d. (the same as oil); or with a fish-tail burner, about 1s. 6d. The comparative cost of incandescence electric light may be put at 1s. 2d.

Air-gas. To some extent in this country, and far more largely in America, air saturated with the vapour of petroleum spirit is employed as an illuminating agent under the name of *air-gas*, and various mechanical devices are employed to effect uniform saturation under varying conditions. The air-gas may be used with ordinary gas-burners, or, after admixture with a further quantity of air, may be burned under a mantle. A portable lamp has been introduced in which the spirit is absorbed by a porous material and gradually vaporised, the heavy vapour flowing by gravitation to the burner and drawing in the air required to produce a non-luminous flame for heating a mantle.

Oil-gas. In order to produce a permanent gas of high illuminating power (50 candles) capable of bearing compression to 10 atmospheres, for use in lighting railway trains, buoys, and lighthouses, a suitable description of petroleum is slowly introduced into a retort maintained at a cherry-red heat.

Carburetted Water-gas. A similar description of oil is also very largely used by the principal gas companies in the manufacture of carburetted water-gas, and as a substitute for cannel coal in enriching coal-gas. In the Lowe system, used in English gasworks, water-gas is formed by blowing steam through incandescent coke or anthracite in a generator. This gas is passed through a superheater, where the oil is added, and the mixture of oil-vapour and water-gas is then taken through another superheater of large size in which the hydrocarbons are converted into permanent gas.

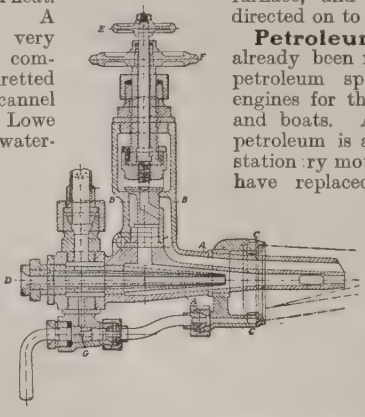
Natural Gas. Certain portions of the petroliferous territories of the United States yield natural gas, which is largely used for lighting and heating, as well as in the manufacture of lamp-black. The gas may usually be burned with an Argand or fish-tail burner, but the best results are obtained with a mantle. For some time natural gas was used to light the railway and town at Heathfield, in Sussex, where it was accidentally discovered, [See page 5417.]

Liquid Fuel. Crude petroleum is employed in the oil-fields, for steam raising, and in refineries, as a means of heating the stills; but the presence of very volatile constituents is a source of risk in storage and handling. Accordingly, either petroleum residuum, which remains in the stills after the separation of the kerosene from such crude oil as that of the Russian oil-fields, or a suitable distillate, with a specified minimum flash-point, is employed on steamships and locomotives, as well as in most industrial establishments where liquid fuel has taken the place of coal. In the British mercantile marine the minimum flash-point is 150° F., but for use in the Navy, liquid fuel is required to have a flash-point of 175° F. It is also needful that the oil should bear exposure to a low temperature, say 32° F., without solidifying.

On the Caspian Sea, and on the railways of Southern Russia, petroleum residuum (ostatki) is the sole fuel; and in California the consumption of liquid fuel has reached very large dimensions. It is common knowledge that the British Admiralty has adopted oil fuel as an adjunct to coal in the modern battleships and armoured cruisers.

Oil fuel is also not only largely used in the furnaces of stationary steam boilers, but is giving highly satisfactory results in metallurgical work, glass melting, and the like.

The oil is usually burned by spraying or atomising it by means of steam, but in some cases is broken up into small particles by forcing it under high pressure through a small orifice. The Holden burner, employed in this country on the locomotives of the Great Eastern Railway, is shown in **4**. The oil is admitted to the interior of the coned body AA through a regulating valve, BB. The annular steam jet D is provided with a central air-passage. CC is an annular chamber to which steam is admitted, and from which it escapes in jets through six small orifices. E and F are wheels by means of which the valves controlling the supply of fuel may be opened or closed. The cock G regulates the supply of steam to CC. The burner is fixed in the front of the furnace, and the intensely hot flame is directed on to a sloping bridge of firebrick.



4. HOLDEN BURNER FOR LIQUID FUEL

Petroleum Engines. Reference has already been made to the extensive use of petroleum spirit in internal-combustion engines for the propulsion of road vehicles and boats. A less volatile description of petroleum is also very largely employed in stationary motors, which in many instances have replaced steam engines and gas engines. In steam engines of moderate dimensions only 12 per cent. of the heat-value of the fuel burned in the boiler furnace appears in the engine as indicated work, whereas, in the internal-combustion engine, the proportion of heat rendered effective is, in many cases, more than double that percentage, and in the Diesel engine is as high as 37 per cent. The superior economy of the oil engine is therefore very marked. Preference is generally given to those engines in which one explosion occurs for each two revolutions of the crank-shaft. The first forward stroke of the piston draws in the explosive charge of oil or oil-vapour and air, and the return stroke compresses it. During the next forward stroke, the explosion drives the piston, and on the return stroke the products of combustion are discharged from the cylinder. The Priestman, Hornsby-Akroyd, Trusty, Tangye, and Diesel engines may be taken as typical of the principal forms of oil-motors. The Priestman engine is fitted with a spray-producer, as well as a vaporiser, and the charge is ignited by means of an electric spark. In the Hornsby-Akroyd engine, the explosion is effected by injecting the oil into a red-hot chamber, into which heated air is forced by the piston. In the Trusty engine, the oil is vaporised and the charge is fired by means of an igniting-tube maintained at a red heat. The Tangye engine also has a vaporiser and an ignition-tube. In the Diesel engine, the air admitted to the cylinder is heated, by very high compression, to such a temperature as to cause the immediate combustion of the injected charge of oil.

BOVERTON REDWOOD

The Ambiguous Case. Worked Examples Illustrating the Four Cases. Examples and Answers.

SOLUTION OF TRIANGLES

44. Case Two of Solution of Triangles. Given one side and two angles, say a, B, and C. Since the three angles of a triangle equal 180°, we have $A = 180° - B - C$.

Again, $\frac{\sin A}{a} = \frac{\sin B}{b}$, so that $b = \frac{a \cdot \sin B}{\sin A}$.

Similarly, $c = \frac{a \cdot \sin C}{\sin A}$.

These two equations give the values of b and c.

Adapting these formulæ to the use of logarithms, we have

$$\log b = \log \frac{a \cdot \sin B}{\sin A}$$
$$= \log a + \log \sin B - \log \sin A$$
$$= \log a + (\mathrm{L} \sin B - 10) - (\mathrm{L} \sin A - 10)$$

or, $\log b = \log a + \mathrm{L} \sin B - \mathrm{L} \sin A$.

Similarly,

$\log c = \log a + \mathrm{L} \sin C - \mathrm{L} \sin A$.

45. Case Three of Solution of Triangles. Given two sides and the included angle, say b, c, and A. We have $B + C = 180° - A$, which gives the value of $(B + C)$. Then, from Article **40**,

$$\tan \frac{B - C}{2} = \frac{b - c}{b + c} \cdot \cot \frac{A}{2}.$$

This gives the value of $\frac{B - C}{2}$, and therefore of $(B - C)$. Having obtained the values of $(B + C)$ and $(B - C)$, the values of B and C can be found.

Finally, since $\frac{a}{\sin A} = \frac{b}{\sin B}$, or $a = \frac{b \cdot \sin A}{\sin B}$, we obtain the value of a.

To arrange the method for logarithmic work we proceed thus :

$$\tan \frac{B - C}{2} = \frac{b - c}{b + c} \cdot \cot \frac{A}{2}.$$

$$\therefore \log \tan \frac{B - C}{2}$$
$$= \log (b - c) - \log (b + c) + \log \cot \frac{A}{2};$$

or, adding 10 to each side of the equation,

$$\mathrm{L} \tan \frac{B - C}{2} = \log (b - c) - \log (b + c) + \mathrm{L} \cot \frac{A}{2}.$$

And, as in Article **44**, from $a = \frac{b \cdot \sin A}{\sin B}$, we get

$$\log a = \log b + \mathrm{L} \sin A - \mathrm{L} \sin B.$$

46. Case Four of Solution of Triangles. Given two sides and the angle opposite one of them, say b, c, and B.

Since, $\frac{\sin C}{c} = \frac{\sin B}{b}$,

$$\therefore \sin C = \frac{c \cdot \sin B}{b}. \quad \ldots \quad (1)$$

C can be found from this equation. Then, having found C,

$$A = 180° - B - C.$$

The value of a is found, as in the last article, from the formula $a = \frac{b \cdot \sin A}{\sin B}$.

47. The Ambiguous Case. In the case considered in Article **46**, the solution of equation (1) gives the value of the *sine* of C. Now, when C is an angle of a triangle, and the value of *sin* C is known, C itself may have *two* values, one of them being less than 90°, and the other being between 90° and 180°.

Hence, there *may* be *two* triangles in which b, c, and B have the given magnitudes. Whether this is so may be decided as follows :

1. If B (the given angle) is *greater than* 90°, C must be *less than* 90°, since any two angles of a triangle must be together less than two right angles. Therefore, when B is greater than 90°, there is only one triangle which satisfies the given conditions.

2. When B (the given angle) is less than 90°, four things have to be considered.

(i.) Is b less than $c \cdot \sin B$? If so, then, since $\sin C = \frac{c \cdot \sin B}{b}$, the value of sin C is greater than 1, which is impossible [Art. **15**]. In this case there is *no* triangle which satisfies the given conditions.

(ii.) b may be *equal* to $c \cdot \sin B$. We should then have $\sin C = 1$, and therefore $C = 90°$. In this case, then, there is only *one* triangle.

(iii.) If b is greater than $c \cdot \sin B$, but *less than* c, then B is less than C [Geometry, *Prop.* 21], and therefore C may be acute or obtuse. Hence, C may have either of the values found from the equation $\sin C = \frac{c \cdot \sin B}{b}$, and there will then be *two* triangles satisfying the given conditions. This is the *ambiguous case* in the solution of triangles.

(iv.) If b is equal to or greater than c, then B is equal to or greater than C. Hence, C must be an acute angle, and therefore there is again only one triangle satisfying the given conditions.

48. We shall conclude with examples illustrating each case in the solution of triangles.

Example 1. Given that $a = 40$, $b = 51$, $c = 43$,
$\log 2 = \cdot 3010300$, $\log 3 = \cdot 4771213$,
$\log 67 = 1 \cdot 8260747$.
$\mathrm{L} \tan 24° 44' 13'' = 9 \cdot 6634464$, find A.

Here, $a+b+c=40+51+43=134$.

$\therefore s=67,\ s-a=27,\ s-b=16,\ s-c=24.$

$$\therefore \text{L tan } \frac{A}{2} - 10$$
$$= \tfrac{1}{2}\{\log 16 + \log 24 - \log 67 - \log 27\}$$
$$= \tfrac{1}{2}\{\log 2^4 + \log 3 + \log 2^3 - \log 67 - \log 3^3\}$$
$$= \tfrac{1}{2}\{4\log 2 + \log 3 + 3\log 2 - \log 67 - 3\log 3$$
$$= \tfrac{1}{2}\{7\log 2 - 2\log 3 - \log 67\}$$
$$= \tfrac{1}{2}\{2{\cdot}1072100 - {\cdot}9542426 - 1{\cdot}8260747\}$$
$$= \tfrac{1}{2}\{2{\cdot}1072100 - 2{\cdot}7803173\}$$
$$= -\tfrac{1}{2}\{{\cdot}6731073\} = -{\cdot}3365536 = \bar{1}{\cdot}6634464.$$

$$\therefore \text{L tan } \frac{A}{2} = 9{\cdot}6634464$$
$$= \text{L tan } 24^\circ\ 44'\ 13''.$$
$$\therefore A = 2\times(24^\circ\ 44'\ 13'') = \underline{49^\circ\ 28'\ 26''}.$$

EXAMPLE 2. In the triangle ABC, the base AB is 1,000 ft. long, and the angles at A and B are 31° 20′ and 125° 19′ respectively. Find the length of AC.

We are given A, B, and c.

First, $C = 180^\circ - 31^\circ\ 20' - 125^\circ\ 19'$
$= 23^\circ\ 21'$.

Again,

$\log b = \log c + \text{L sin B} - \text{L sin C}$
$= \log 1000 + \text{L sin } 125^\circ\ 19' - \text{L sin } 23^\circ\ 21'$
$= \log 1000 + \text{L sin } 54^\circ\ 41' - \text{L sin } 23^\circ\ 21'$
$= 3 + 9{\cdot}9116739 - 9{\cdot}5980754$
$= 3{\cdot}3135985$
$= \log 2058{\cdot}725.$

Thus, AC = <u>2058·725 ft.</u>

EXAMPLE 3. Two sides of a triangle being 2265·4 ft. and 1779 ft., and the included angle being 58° 17′, find the remaining angles of the triangle.

Suppose $b = 2265{\cdot}4$, $c = 1779$, and $A = 58^\circ\ 17'$.

Then, $B + C = 180^\circ - 58^\circ\ 17' = 121^\circ\ 43'$.

Again, $\text{L tan } \dfrac{B-C}{2}$

$$= \log(b-c) - \log(b+c) + \text{L cot } \frac{A}{2}$$
$$= \log 486{\cdot}4 - \log 4044{\cdot}4 + \text{L cot } 29^\circ\ 8'\ 30''$$
$$= 2{\cdot}6869936 - 3{\cdot}6068541 + 10{\cdot}2537195$$
$$= 9{\cdot}3338590$$
$$= \text{L tan } 12^\circ\ 10'\ 21''.$$

$$\therefore \frac{B-C}{2} = 12^\circ\ 10'\ 21''$$

and $(B-C) = 24^\circ\ 20'\ 42''$.

But $(B+C) = 121^\circ\ 43'$.

$\therefore 2B = 146^\circ\ 3'\ 42''$

and $2C = 97^\circ\ 22'\ 18''$.

Hence, $B = 73^\circ\ 1'\ 51''$, $C = 48^\circ\ 41'\ 9''$ } *Ans.*

EXAMPLE 4. The lengths of two sides of a triangle are 5374·5 ft. and 1586·6 ft.; the angle opposite to the shorter side is 15° 11′. Calculate the other angles of the triangle, or of the triangles, if there are two.

Suppose $b = 1586{\cdot}6$ ft., $c = 5374{\cdot}5$ ft., and $B = 15^\circ\ 11'$. Then,

$\text{L sin C} = \log c + \text{L sin B} - \log b$
$= \log 5374{\cdot}5 + \text{L sin } 15^\circ\ 11' - \log 1586{\cdot}6$
$= 3{\cdot}7303381 + 9\ 4181495 - 3{\cdot}2004674$
$= 9{\cdot}9480202$
$= \text{L sin } 62^\circ\ 31'\ 23''.$

$\therefore C = 62^\circ\ 31'\ 23''$,

or $180^\circ - 62^\circ\ 31'\ 23'' = 117^\circ\ 28'\ 37''$.

And b is less than c, therefore both these values are admissible.

Thus there are two triangles.

(i.) $B = 15^\circ\ 11'$, $C = 62^\circ\ 31'\ 23''$, so that $A = 102^\circ\ 17'\ 37''$.

(ii.) $B = 15^\circ\ 11'$, $C = 117^\circ\ 28'\ 37''$, $A = 47^\circ\ 20'\ 23''$.

EXAMPLE 5.

Given that $C = 52^\circ\ 10'$, $b = 643$ yd., $c = 872$ yd., find the other angles.

$\text{L sin B} = \log b + \text{L sin C} - \log c$
$= \log 643 + \text{L sin } 52^\circ\ 10' - \log 872$
$= 2{\cdot}8082110 + 9{\cdot}8975162 - 2{\cdot}9405165$
$= 9{\cdot}7652107$
$= \text{L sin } 35^\circ\ 37'\ 7''.$

$\therefore B = 35^\circ\ 37'\ 7''$,

or, $180^\circ - 35^\circ\ 37'\ 7'' = 144^\circ\ 22'\ 53''$.

But b is less than c, therefore B must be less than C. Hence, the second value found for B is inadmissible.

Thus $B = 35^\circ\ 37'\ 7''$, and

$A = 180^\circ - 35^\circ\ 37'\ 7'' - 52^\circ\ 10' = 92^\circ\ 12'\ 53''$.

The above examples, with the exception of Example 1, are worked direct from the Tables of Logarithms. As already mentioned, the method of finding the logarithm corresponding to a given number or trigonometrical ratio, or the number or angle corresponding to a given logarithm, is explained in the book of logarithms.

EXAMPLES

1. When $a = 759{\cdot}3$, $b = 576{\cdot}2$, $c = 374{\cdot}5$, find C.

2. Find c, when $A = 50^\circ$, $C = 66^\circ$, a = 1000, having given

L sin 50° = 9·8842540
L sin 66° = 9·9607302
log 1·19255 = ·0764762

3. The angle A is 70° 30′, and the ratio of b to c is 5 : 3. Find the other angles, having given

L cot 35° 15′ = 10·1507464
L tan 19° 28′ 50″ = 9·5486864
log 2 = ·3010300

4. Find A, having given $b = 960$, $c = 1404$, B = 32° 15′

log 2 = ·3010300 — L cosec 32° 15′ = 10·2727724
log 3 = ·4771213 — L sin 21° 23′ = 9·5621316
log 13 = 1·1139434 — L sin 51° 18′ = 9·8923236

ANSWERS

1. 28° 35′ 39″
2. 1192·55
3. B = 74° 13′ 50″, C = 35° 16′ 10″
4. A = 96° 27′ or A = 19° 3′

MATHEMATICS CONCLUDED—END OF GROUP 25

ONE OF THE WONDER-SIGHTS OF THE WORLD

THE MARVELLOUS SIGHTS THE TRAVELLER SEES IN SWITZERLAND—A CREVASSE 800 FEET DEEP ON THE GLACIER DU GÉANT

The Study of Town and Country at Home and Abroad.
Why, How, and Where to Go in Days of Peace.

EDUCATION THROUGH TRAVEL

FROM the earliest days when our forefathers began to study methods of education, they realised the need for education by travel. Shakespeare expressed the need in a sentence: "Home-keeping youths have ever homely wits." If that generalisation is taken as meaning that no one can be a cultured man of the world without seeing the world, it is, perhaps, too sweeping, for observation, reflection, science, and reading may conceivably educate a man fully, though they are exercised within the narrow sphere of rural life, provided he is endowed with much breadth and strength of mind. But such a man, though a possibility, remains a rarity. Without travel, he may be truly cultured; with travel, he would have attained a fuller development, and his powers would have expanded more freely under richer enjoyments.

Some Uses of Travel. Unless we travel we cannot hope to appreciate the influence of scenery on the minds of men. Though photography is useful in recalling what we have seen, it fails utterly to suggest the grandeur and beauty of the world to those who have not received direct impressions. Who, for example, can imagine the upper world of ice and snow? Unless we travel we cannot realise either the character or the economic conditions of people of other lands. We cannot form comparative opinions of the art of different regions and ages; nor can we come into vital touch with much of the world's most formative history. Reading of the past in a book is but a pale shadow of the history that may be felt on the scenes of its enactment. The increment of knowledge and experience from travel alters more or less insensibly our point of view, even of familiar things. Further, it may be placed to the credit of travel that it stimulates a practical knowledge of languages, and at the same time is one of the most refreshing forms of recreation.

Preparation for Travel. Travel, then, being so important, it is well that everyone should prepare for it in some measure, and map out his life so as to admit of it, sooner or later. All successful travel depends in a large degree on preparation. The traveller must know beforehand exactly where he is going, and what he ought to see in each place. Even if he goes abroad at first with a crowd, conducted by an agency, he should study, before starting, his own maps, railway guides, guide-books, and histories, and prepare himself for speaking enough of the language to "get along" alone if need be. No one travels truly who does not travel on his own account, and, from the first, independent travel should be aimed at by all who can hope to speak a little travellers' French.

Tickets. Tickets for the main lines are best taken beforehand through one of the agencies, but nothing is gained by booking a fixed route off the main lines. For example, anyone visiting France along the route Dieppe, Rouen, Lisieux, Caen, Coutances, Dinan, Morlaix, Quimper, Auray, Rennes, Le Mans, Chartres, Paris, and Dieppe, would get all the cheapness possible by taking a return ticket to Paris, and not using the outward section between Rouen and Paris. All the rest of the journey is simply the ordinary fare, and by not booking beforehand the traveller retains his freedom of movement.

Routes. In planning a travel-tour, the inexperienced traveller should avoid, above all things, the conceit of getting "off the beaten tracks." The tracks which are beaten are the best tracks. That is why they are "beaten." He sees there what is finest, and sees it easily.

As regards expenses, hotel charges have increased greatly in recent years, and no guide-book can be trusted, but *pension* charges are still reasonable, and the food and accommodation at good *pensions* compare favourably with the hotels which charge twice the *pension* prices.

England and Wales. A good deal may be said for travel in the British Islands before the Continent is visited extensively. By touring at home, much advantage, similar to that of foreign travel, can be gained. People who go year by year to one holiday resort are wasting many chances of experience, and may form habits of restfulness which unfit them for seeing any other place properly. Only the rambler learns how to know a district, whether he rambles on foot—much the best way—or by cycle, or by motor-car.

None can claim to know the British Islands adequately who has not *walked* the English Lake District, both through the passes and over the "tops," from Skiddaw to Coniston Old Man, and from Mardale to Wasdale; explored North Wales from Conway to Barmouth, peak by peak and stream by stream; traced the lovely valleys of the Upper and Lower Wye; followed the coast of Devonshire and the hinterland moors from Minehead to Ilfracombe; glanced at Clovelly, and tramped the Cornish coast past Hartland, Bude, Boscastle, and Tintagel to Padstow, Bedruthan, and Newquay; explored the Land's End region from St. Ives round to Penzance and the Lizard; sampled the wooded rivers of the south—the Fal, the Fowey, the Looe, the Tamar, and the Dart; crossed Dartmoor; compared the lovely little "combe" coves by Torquay with the sheltered nooks on the eastern side of the Exe—Budleigh Salterton, Sidmouth, and Bere—and the stern "ledges" of the Dorset coast; surveyed the Great Heath of the Hardy novels

from the Purbeck Hills; known the glades and copses of the New Forest; skirted the Isle of Wight; followed the great back of the North Downs; discovered that Kent is the real Garden of England; sailed on the lazy waters of inland Norfolk; felt the sobering influence of the wide Fenlands from some such ancient capital as Crowland; gazed over all central England from the worn but wooded granite core of Charnwood; tramped the dales and moorlands of Derbyshire and of Yorkshire, west, north, and east; crossed the back of the Pennines from High Teesdale or the Upper Tyne; and studied the historic cities and towns that are England's pride—London, Canterbury, Oxford, Cambridge, Winchester, Salisbury (with Stonehenge), Bath, Stratford-on-Avon, Norwich, Lincoln, York, and Whitby.

Scotland and England. At least an equal charm awaits the wanderer through the parts of Scotland associated with the personal memories of Burns and Scott; the lochs, salt and fresh, and the islands of the outer Clyde region; the still wilder mountain lands and islands northward of Oban; the lovely glens and spacious moors reached by the Highland railways; the incomparable valley of the Dee, leading up to the recesses of the Cairngorms; and the romantically placed centres of Scottish history—Edinburgh, Stirling, and Inverness.

No whit behind, and wearing a quite distinctive beauty, are well-nigh the whole coastal regions of Ireland—the graceful hills and sweet glens of Wicklow; the lovely reaches of the Blackwater; the enchanted route by Bandon and Glengariff to Killarney; the inlets of Kerry; the cliffs of Clare swept by the mighty Atlantic; the lovely sternness of Connemara, changing into the softness of Sligo, and again to the barren heights of Donegal; the noble coastline of Antrim, and the "Mountains of Mourne sweeping down to the sea." Who would linger holiday after holiday in a single seaside resort, when these glories of our islands, so varied in their enthralment, are waiting to delight us, and to offer us travel experiences scarcely to be surpassed by the enchanting foreign lands which beckon all the people of the world?

Belgium and Holland. When we have seen the British Islands reasonably well, or are prepared to alternate holiday rambles in the homelands with holidays abroad, where should we begin our Continental experiences? Many, lured by cheapness, organised travel, and the call of the mountains, go straight to Switzerland—to Lucerne, Grindelwald, Chamonix, or Zermatt. But it is not good management. After Switzerland, almost any other part of Europe is an anti-climax. There one does nothing but absorb, out of doors, scenic impressions; and that habit is almost antagonistic to the mood that should be dominant during the greater part of Continental travel. It is the mood of study—with gladness and lightness of spirit, but still study—that is most fitting; and Switzerland only casts over the senses the glamour of sheer enjoyment. Besides, Switzerland is on the way back from many places that should be seen and studied; and so in Switzerland invigoration may be suitably sought for a few days at a time *after* holidays elsewhere that were educationally remunerative but not physically stimulating.

The most natural and well-graded holiday to begin Continental travel with is a tour of Belgium and Holland. These countries are near, their internal distances are short, and living in Belgium is cheap, so that the total cost is low. The traveller has opportunities of testing his French, though English is fairly well known in the cities. Above all, Belgium is a great vestibule to the mediæval art of Northern Europe. It is not only the vestibule, but the chief court of the temple.

The right route to follow, so as to see the art treasures of Belgium in their proper sequence, is, first, Bruges, then Ghent, then Brussels, and, later, Malines and Antwerp. From Antwerp a tour of Holland may be made for the sake of its picturesque quaintness, the round including Delft, The Hague, Leyden, Haarlem, Amsterdam, and the Zuyder Zee, returning by Utrecht and Dordrecht to Brussels, from which, as a closing complement to the town studies of art and a storied past, a refreshing visit may be paid, by Namur and Dinant, to the romantic woodlands of the Ardennes.

Bruges, Brussels, Antwerp. In no part of Europe is travel more truly educative than in Belgium, if it be thoughtfully prepared for. Bruges is the town which shows best the rise of Flemish culture. It is the oldest and best preserved of the merchant centres which gave to early art and learning patronage and defence. Once it vied with Venice as the home of commerce. Its choicest treasures are its pictures by Memling in the Hospital of St. John, its Notre Dame, its city buildings, its picture gallery, and its quaint old houses. Anyone who cares nothing for the history of art should keep away from Belgium. Ghent is famous for its "Adoration," by the Van Eycks, in the internally fine Cathedral of St. Bavon, and for its Gothic Hôtel de Ville. Brussels has a wonderful Town Square and a noble cathedral. It also has art galleries which illustrate completely the paintings of the Flemish schools. Malines has a very beautiful cathedral and an air that tones the mind to the past. Antwerp, belonging to a later period than Bruges, is dominated by Rubens. It has a glorious cathedral and a unique eighteenth-century printers' museum—the Plantin-Moretus—which is one of the choicest historical memorials in Europe.

Touring in France. An alternative beginning for Continental travel, competing with Belgium, is a tour in France. The best route at first is that already outlined, from Rouen through Normandy and Brittany, and back to Paris, with a trip from Rouen down the Seine to Caudebec added during the return journey from Paris. Paris itself is certain to be visited often by those who go abroad, for it is an almost indispensable stopping-place going and returning, as it lies at just the right distance from London for a rest. What the visitor most needs to realise is that Paris is much more than a busy and cheerful modern city. It is a great historical centre, like London, and ministers

to the student as completely as to the fashionable spendthrift. Until historical Paris is known, the true Paris is unknown. The Champs Elysées and the shopping streets are no more Paris than Rotten Row and Regent Street are London.

If we group the Chamonix district with Switzerland, the best of France may be seen in three tours. Towns like Amiens and Rheims, on main lines, will fit in suitably, as resting-places, when journeys farther afield are beginning or ending. But Normandy with Brittany, the Loire district and Central France, and the Dauphiné, must be separately visited, each furnishing a full holiday round.

Through Brittany. The features of the north-western tour are the noble cathedrals of Normandy and the intimate associations between the early histories of the Dukedom and the English kingdom. Then, farther westwards, the characteristics of the Breton race, and the curious linking of their religion, finely expressed in mediæval cathedrals, with the earlier Nature-worship of vanished peoples. The cathedrals and abbeys of Rouen, Lisieux, Caen, Bayeux, Coutances, Mont St. Michel, Dol, Quimper, Angers, Le Mans, and Chartres make up a round which, architecturally and historically, is unequalled elsewhere. The French railways, too, have the happy peculiarity of arranging midday breaks of three or four hours, which allow the traveller to see one small cathedral town and reach another for the night's rest.

Central France. Another tour from Paris would include Orleans, Blois, Tours, Saumur, Poitiers, Angoulême, Limoges, Perigueux, Brive, Aurillac, Clermont, Nevers, and Bourges, thus combining the cathedrals and castles of Central France with the interesting volcanic mountains of the Auvergne. The ideal ending to this route, were it not somewhat long, would be to continue from Clermont-Ferrand southward to the splendid remains of antiquity at Nîmes, Arles, and Orange and the papal memories of Avignon, finishing with an invigorating visit to the Dauphiné Alps, with Grenoble and Chambéry as centres; or this latter extension may be taken as a separate holiday, with Dijon as a resting-place on the way to or from Paris.

Most of the other inviting districts of France, such as the Vosges, the Jura, the Riviera, and the resorts along the foothills of the Pyrenees, are on, or but a little way aside from, great "through" railways, and may be visited en route, as a change from more studious travel.

Up the Rhine. One of the travel-trips that should be treated as an approach to Switzerland is the little journey up the Rhine between Bonn and Mayence. To return by this route from Switzerland is to deprive the Rhine of all chance of distinction. The dullness of the stream before Cologne and Bonn is needed to prepare the mind for enjoyment of the pleasant scenery which follows, and between Coblentz and Bingen grows romantic. Part of the reputation of the Rhine depends upon the ease with which the river is seen—from the deck of a quiet steamer amply provided with creature comforts.

On the left bank of the Rhine, starting from either Remagen or Andernach, is the Eifel volcanic country, one of the most delightful of the quaint and simple areas of Europe. It richly repays a ten days' ramble. In recent years it has become very well served by hotels at reasonable rates. Before, it was too primitive for the average traveller.

A short railway journey beyond Mayence is Heidelberg; another short stage reaches Strassburg; a third, and we are at Freiburg and the borders of the Black Forest. These cities are all interesting, and the Forest is the most fascinating stretch of woodland in Europe. The popular route is through the Hollenthal to Titisee, and thence southward to the Rhine at Waldshut, but it is impossible to fail to find beauty in this land of blue mountains and woods. On reaching the Rhine, Schaffhausen (with the Falls of the Rhine) and Basle are close by on either hand; and this gentle holiday, with the Rhine as a guiding line, may be fitly closed at Lucerne, where the greater mountains are approached, and the upper snow-world becomes a presence in the distance.

The Quality of Swiss Scenery. So we have reached Switzerland, the bourne of all who travel to enjoy natural beauty. Unquestionably Switzerland is the most attractive country in the world, judged by grandeur, loveliness, and accessibility. Its only close competitor is Tyrol, which has a charm all its own, but lacks the alternations of mountain and lake, and of sweetness with strength. The lakes of Tyrol are only mountain tarns. The lakes of Switzerland brighten some of its broadest landscapes. Both lands have mountains of haunting outline, such as are rare elsewhere. Norway, for example, and the most vaunted parts of the Canadian Rockies have no peaks comparable in distinctive character with the Matterhorn, the Jungfrau, Mont Blanc, Monte Rosa (as seen from the south), and the Weisshorn, in the Western Alps, the Croda Rossa, Antelao, Drei Zinnen, and Ortler Spitz in Tyrol. The finest road-route in Europe is the Stelvio, which climbs to a point where Tyrol, Switzerland, and Italy meet, and so adjusts their rivalries. [See p. 5043.]

Beaten Paths Best. Popular travel has been singularly successful in reaching the finest mountain centres of Switzerland—Lucerne on the northern fringe, Grindelwald and Kandersteg in the centre, Chamonix (France) in the south-west, Zermatt nestling under the great circle of the southern mountain belt, Pontresina towards mid-east. But nobody sees this country as it should be seen who does not leave the railway and cross the chief passes by road, for the Albula and St. Gothard are the only passes that can be said to be superseded, or represented, by their rail routes. The Via Mala, Splugen, and Maloja Passes remain by far the finest route to the Engadine for all who wish to travel instead of merely getting there. The Simplon railway does not in any sense represent the Simplon Pass; and the new short railway cut into the Rhone Valley from the Oberland will never supersede the Gemmi or the

Grimsel Passes with the genuine Nature-lover who is not bound to rush. No one can understand what he sees when he gazes on a great array of mountain outlines until he has conquered lofty heights at a foot's pace, and knows what rocks and glaciers look like both near and far off. It is quite possible that to many an unobservant person who arrives at the Wengern Alp by train, the Eiger, Monk, and Jungfrau are only three white humps just over the way. This type of traveller never knows enough to be impressed.

The effects of travel in Switzerland, apart from stimulation by a health-giving climate, are solely sensuous. They remain only with the passionate lovers of the sublime mountains. But, to such, life in Switzerland is a dream visited by all that is delightful. There is little to study, or that links the present and the past. All the history of the land that is of great importance can be read in half an hour. The present is the most impressive of all periods, particularly from the points of view of industry, education, and defence. In Switzerland we simply enjoy.

The Rival of Switzerland. In many respects, Tyrol, the traditional enemy of Switzerland, is like her. The best way to Tyrol shows the traveller the industrial north of Switzerland—Zürich in particular—then it tunnels from the upper Rhine valley under the Arlberg, and descends to Innsbruck, the most beautifully placed considerable town in Europe. When one has passed beyond Switzerland all roads lead to Innsbruck. Near and far it is surrounded by beautiful districts that need several holidays for a hasty glance. To the north-east is the Austrian lake-district, the Salzkammergut beyond Salzburg, a lovely intermixture of lake and peak and wood; to the north, the romantic highfields of Bavaria have Berchtesgaden to the east and Ober-Ammergau to the west; south-westward lies the Engadine; and southward and south-eastward the abrupt, lightning-riven peaks of the Dolomites, in the midst of which are valley nooks of unsurpassed beauty. A good road from Toblach via Cortina to Campitello, Karer See, and Botzen now opens up the centre of this formerly inaccessible region. Southward from Innsbruck the Brenner Pass, the "German road" of the Romans, passes into Italy to Verona, while farther to the west the way out from the mountain-hemmed Tyrol is over the stupendous Stelvio, a summer route which climbs to more than 9000 feet. This beautiful country competes with Switzerland for the admiration of the lover of fine scenery. The southern slopes of the Tyrolean mountains, by the way, are Italian, and formed a friendly hinterland for Venice in the days of her greatness.

Some German Centres. The rural parts of Germany beyond the region of the Rhine that are attractive to visitors are the Hartz Mountains, between the middle courses of the Rivers Weser and Saale, and the Thüringen Forest, around the sources of those rivers. German cities that ought to be visited are Dresden, for its art treasures, and Munich, for its art treasures and modern institutions, but, above all, Nuremberg, one of the three or four European cities which retain a mediæval atmosphere in so large a measure as to impress the least receptive. Of the Germanic capitals, Berlin and Vienna, the first is a large, obtrusive place, showy and aggressive, with no distinction; the second is much finer, whether regarded from a historical point of view or as a repository of the products of human taste and knowledge.

Italian Scenery. Italy, of course, is the final goal of all who travel that they may know and feel. The scenic attractions of this fascinating land are great, from the Alps, whose summits make the frontier, and whose steepest sides often fall into Italy, and from the sweetly sheltered lakes which hold back the Alpine waters from the Italian plain, down to the fruit-garlanded coves of the rocky Italian Riviera, the gloriously green landscapes of the Tuscan valleys, and on to the wildly romantic precipices of the Amalfi coast in the south. But the real call to the traveller comes from the Italian past. Nowhere else is the sense of time and of human change so impressively aroused.

The Pageant of History. Rome, Florence, Venice—there you have the story of two thousand years made clear, between the old Empires of the East and our modern history.

Rome must begin the tale. The traveller who looks around him in Rome with any clearness of vision must see signs of at least seven epochs—first, the simplicity of Republican Rome from which all Roman virtues sprang; second, the magnificence of imperial Rome; third, the struggling emergence of Christianity; fourth, the chaos following barbaric destruction; fifth, the great revival of Christian art that came to Rome, largely from Florence; sixth, an age of neglect of the treasures of antiquity; seventh, the modern period of business energy, accompanied by a wise care for the past. In Florence, the glorious home of Italian artistic genius, one phase of this evolution is impressively seen, and in Venice another. Many other Italian towns play their parts, notably Pisa, which commemorates in marble the stemming of the onrush of the Mohammedan hosts across the Mediterranean.

The spoils brought home from Italy by the traveller—the harvests of the mind and heart, that is—are richer than those from elsewhere, because they combine much from Nature, since the land is beautiful; even more from art, for here was a direct inheritance from the art of Greece and a reflowering, in painting, into a loveliness the Greeks never knew; and withal there is an abundant ministration in Italian scenes to historical perception, serious thought, and religious impulse.

In the Mediterranean. Travel in other lands must be referred to even more compendiously. There are now many opportunities of visiting various parts of the Mediterranean where our civilisation was in a large degree evolved. The islanded shores of the Adriatic, so long held back from prosperity by turbulence

inland, can be traced to the sunny isles of Greece; but, except to the expert classical scholar, Greece, even from its very heart in Athens, does not exercise the influence over the imagination which exhales, as it were, from Rome. The reign of tangible power in the case of Greece was too short—a mere flash—though the influence of the Greek mind is everlasting. As with Palestine, so with Greece: the sights of today give but little help to the reverence that would interpret the glorious past.

The Birthplace of Civilisation. The only country within holiday reach, except Italy, that preserves adequately a feeling of a vanished civilisation is Egypt, but the Egyptian civilisation, though powerfully suggested by the ruins which have been so industriously uncovered, is alien to Western feeling in comparison with that of Rome. Many shrink from examining with care the deeper layer of history; and to the average traveller Egypt is primarily a land of a delightfully equable climate, refreshing to the jaded, and offering the air of the desert like a precious vintage. This practical view of Egypt shows the good sense of the average traveller; for while the world owes an incalculable debt to the masters of Egyptology, the travellers who have but a little knowledge of it are among the worst of travelled pests.

THE WINDINGS OF THE FORTH NEAR STIRLING

Unknown Spain. Spain is a country that cannot yet be truly seen by the casual traveller. A journey to the Pyrenean borders of Spain is delightful on the French side, and San Sebastian, just over the frontier, bids high for a first place among seaside resorts that are glorious for situation; but a journey by rail through Spain to Burgos, Madrid, Toledo, Cordova, Grenada, Seville—the usual route—only gives an absurdly casual impression of the country, for the traveller is surrounded all the while by international, and not Spanish, conditions. Such a journey through Spain is almost as artificial as a ride on a switchback railway at a fair. The truth is that Spanish food and accommodation debar the traveller from seeing the country as it is unless he will "rough it." So it is glanced at from a window in the most comfortable season, and the Moorish past is studied with interest, while the present is a sealed book.

The Northern Capitals. A sea journey that is very popular, and may be thoroughly recommended, is the round of the Northern capitals. This usually includes a call at the pleasantly situated city of Christiania; at Copenhagen, where the politeness and charm of the people hide the fact that popular sights are few; Stockholm, a city strewn in a forest beside many waters, and possessing a fine museum of national historic life; and then Petrograd, with a visit to Moscow. Of all travel in Europe outside the unsettled parts of the Balkan Peninsula, this experience of Russia is the freshest and most stimulating to the average British holiday-maker. Everything in Russia is strange, unexpected, delightful. The riches of Russian art treasures, as at the Hermitage in Petrograd, the magnificence of the cathedrals, the musical sonority of the worship, the religious sentiment of the people, their simple, kindly ways, the touch of Eastern colour, the feeling of being hemmed in between an almost barbaric splendour in religion and specialised wealth on the one hand, and a colossal commonplace in the kindly masses on the other hand—these and all other impressions are curious, new, unlooked-for, stimulating, and the effect of a Russian holiday is a fresh start to one's interest in life.

Sombre Norway. Some mention should be made of Norway—the easiest land to visit wholly by sea. The influence of Norway is precisely similar to that of Switzerland; that is, it is an interviewing of Nature in a fresh form. But Norway is sombre—always a little sombre. The long winter nights have settled upon the hearts of the people and made them quiet, almost inert, though very kind. Every voyager to Norway should make a point of going as far north as the Romsdal Fiord, as far south as Bukken Fiord, and of taking at least one land excursion. From Odda to Sand is perhaps the best.

The Peopled Mind. With all these travel-scenes awaiting us, at home and abroad, is it not strange that so many are content to see the same place again and again when the time for a holiday comes round? They have not realised that there is nothing so recreative as a *complete* change; that new scenes and ideas restore us mentally as well as stimulate us physically: and, further, that well-planned travel leaves with us a vast fund of impressions that will supply the mind with material long after travel may have become a burden.

JOHN DERRY.

TRAVEL CONCLUDED—END OF GROUP 2

The Work of Organising British Agriculture. Co-operative Societies and their Objects. The Province of the Board of Agriculture.

CO-OPERATION IN AGRICULTURE

Among the many advances which will always make the nineteenth century notable in history, the co-operative movement may claim a high place, and, being mainly an achievement of the working classes, it is bound to influence profoundly all democratic communities. Co-operation essentially consists in the substitution of "mutual aid" for selfish competition, and in our own country its inception was due to the energy and ability of Robert Owen, whose ideas crystallised into actions in 1821, but the great successes of the movement fall within the last sixty or seventy years. Although the early co-operators included agriculture in their purview, and regarded "community in land" as their goal, other forms of industry were the first to be organised; and it appears to be reserved for this generation to revolutionise agriculture, still "the first and most important industry," by the thorough application of co-operative methods. Some of these we will briefly consider.

The Organisation of Agriculture. It must be emphasised that the interests of *all* classes concerned with the land can be furthered by co-operation, but the best results cannot be expected until mutual trust replaces mutual distrust, the latter being furthered and fomented by our hateful system of party politics.

Agricultural co-operation did great things in such countries as Denmark, France, and Germany before this slow-moving nation perceived its possibilities. The extraordinary prosperity of Denmark, our most serious rival in the dairying and poultry industries, is almost entirely due to the adoption of thorough-going co-operative methods, associated with a genuine system of education (not "cram") sadly to seek in Britain. Sir Horace Plunkett and Father Finlay, students of Continental methods in the 'eighties, founded the Irish Agriculture Organisation Society (I.A.O.S.) in 1889, and this has done far more to make Ireland prosperous than many generations of politicians. The English Agricultural Organisation Society (A.O.S.), founded in 1901, has been forwarding the movement with great success in England and Wales, and the Scottish Agricultural Organisation Society (S.A.O.S.) was founded in 1905. Information and counsel are enthusiastically given by the secretaries of these societies, the respective addresses being—Plunkett House, Dublin; Queen Anne's Chambers, Tothill Street, Westminster, London, S.W.; and 5, St. Andrew's Square, Edinburgh.

A brief survey of the aims and objects of the A.O.S. will give some ideas as to the possibilities of agricultural co-operation.

The Idea of Co-operation. The bed-rock idea of the whole thing is based on the commonplace that men in a large way of business can buy, sell, or borrow on better terms than those whose transactions are on a small scale. From this it follows that a co-operative society of the latter, by trading jointly, is able to secure the best possible terms; and the small-holding movement is bound to fail, except in particular cases, unless this principle is followed.

Aims of the Agricultural Organisation Society. The A.O.S. is controlled by governors whose names inspire complete confidence, and it "exists for the purpose of advocating the principles of co-operation among agriculturalists, and of giving advice and assistance in the formation and organisation of properly registered co-operative agricultural societies in suitable districts throughout England and Wales," these being "entirely self-supporting and self-governed." "The A.O.S. does no trade and makes no profits," a most important statement, for the movement is purely patriotic, and presumably, therefore, no governor has "an axe to grind."

Purchase of Seeds and Implements. The objects of the local Agricultural Co-operative Societies are: *Object A:* "To purchase for their members (1) manures, seeds, feeding stuffs, implements, and the like, on wholesale terms from the manufacturers, importers, or wholesale merchants, a small profit being charged to cover management expenses; (2) to attempt to secure the purity of feeding stuffs, seeds, and manures, the guarantees for which are often misleading or insufficient for the information of the purchaser. Co-operative societies are better able to protect their members in their purchases, for even when the proper guarantees are given, farmers, as individuals, rarely have analyses made."

It must be distinctly understood that a co-operative society differs entirely from a joint-stock company, such as one of the West End London "stores," though these may be called "co-operative" in another sense. But a joint-stock company divides its profits among a limited number of shareholders, while the profits of a genuinely co-operative society are shared by the purchasers, who, in our case, are the farmers, small-holders, and so on, constituting the company.

Picking a case at random from the 1914 report of the A.O.S., we find that during 1913 the West Midland Farmers' Association, with a membership of 419, expended £61,947; and it is quite clear that the 419 members were able to get much better terms, purchasing collectively, than if each man had made his own purchases.

In certain cases a large society can, by forethought, escape from the loss entailed by rise in price of a popular article. A particular and deservedly popular make of binder twine (for use in the reaper-and-binder machine) was so much in demand that its price went up in a marked way. One of the larger societies went to another firm of twine manufacturers, and by ordering some tons in advance was able to secure an equally desirable article at a normal price.

The endeavour of co-operative societies to secure pure feeding stuffs, seeds, and manures is of the utmost practical importance, preventing large waste of money in the actual outlay and promoting good results in crop and stock production. Farming is so complex a business, and profits have been so cut down by colonial and foreign competition, that the business principles regulating other forms of

industry ought to be adopted. One such principle is the division of labour, the share of the farmer in that division being to make the most of his land for productive purposes; and here the British farmer is second to none. He can no doubt judge the value of feeding stuffs, seeds, and manures to a certain extent, but this can only be done in detail by other experts, and these are employed by his co-operative society to ensure that he gets what he pays for, and to protect him against the unjust adulterator who will be a permanent fixture so long as poor human nature remains what it is.

Milk Supplies. *Object B:* "To secure the best market for the sale of produce. (1) By organising the milk supply on a co-operative basis, so that a large proportion of the profits may be secured for the farmers."

Here, as generally, it is a question of eliminating the middlemen who absorb so large a proportion of the profits of agriculture, the aim being for milk to go direct from the producer to the consumer. Considering that various societies have succeeded in securing for their members an advance of from one farthing to a penny per gallon for whole milk, this particular direction of activity would appear to be well worth while.

Butter and Cheese Factories. (2) "By establishing co-operative butter and cheese factories in suitable districts."

The production, at a profit, of butter or cheese by the individual farmer is commonly out of the question, for it is highly skilled work, requiring special facilities. The co-operative factory, operating on a comparatively large scale, is able to buy milk from the farmer for what it may be worth, making from it products of uniform good quality. This is the secret of the Danish success in dairying, for the consumer wants uniform good quality, and gets it every time. Co-operative dairying has proved a conspicuous success in Ireland, and has proved its value in certain parts of Great Britain, where it is advancing steadily.

Egg and Poultry Depots. (3) "By establishing co-operative egg and poultry depots for sorting, grading, and packing."

Not so very long ago the "Irish egg" was proverbial for its doubtful qualities, and the trade was in the hands of middlemen, who collected eggs in a very unsystematic manner, and but little to the benefit of the producer. Co-operation has changed all this, for Irish eggs are now on the English market, properly sorted, graded, and packed, within three days of being laid, and the profits go to the producer. Similar methods are gradually being established in various parts of Great Britain, although progress is not very rapid.

Fruit Packing and Grading. (4) "By grading and packing fruit, in order to place it on the market in a fresh and attractive condition."

Our great fruit-growing areas are beginning to realise that increased profits result from proper grading and packing; and where this is done on co-operative lines, the profits, of course, belong to the growers. Attention is also being paid to the making of chip baskets and other receptacles for fruit.

Sale of Wool. (5) "By organising the disposal of wool, so that sheep-growers may have it properly classed and packed, and so secure good prices from the wool merchants."

This is a new and promising direction of activity, and the advantages are comparable to those given under preceding headings.

Bacon Factories and Pig Sales. (6) "By organising the bacon and pig industries for the benefit of the producers."

Efforts have been so far directed to the disposal of live pigs, the pioneer co-operative society being that of the Eastern Counties Farmers. In 1905 this society dealt with 5681 pigs, value £17,400; in 1913 with 23,082 pigs, value £120,938. Co-operative bacon factories may be expected to follow later.

Markets and Transport. (7) "By organising co-operative markets, to reduce the cost of disposal, and to break down the rings formed against the producer."

This important aim yet remains to be realised.

(8) "To reduce the cost of transport, by bulking consignments and by arranging terms with railway companies and carriers."

Co-operation on these lines is of obvious utility. A railway company, for example, will naturally give favourable terms when large consignments are in question.

Object C: "To open up remote districts by motor traction."

Comparatively little has so far been done in this direction, but in course of time there can be no doubt that motors will so supplement railways that all farmers will have a fair chance of selling their produce to advantage, and will thereby be stimulated to increase their output. Eggs and other products of considerable value in proportion to their bulk are particularly adapted for conveyance by motor; and it is sufficiently clear that co-operative methods are the only ones that can give the best results.

Stock-breeding. *Object D:* "To hire or buy pedigree stallions, bulls, etc., for the use of their members at reasonable rates."

Fortunately, this matter is now actively being taken up by the State, for the Board of Agriculture, aided by advances from the Development Fund, has initiated a Live Stock Improvement Scheme, from which great things are expected. The scheme is especially intended to benefit small farmers and small-holders, many of whom have in the past hardly realised the great importance of "quality" in stock.

Insurance. *Object E:* "To arrange for all kinds of agricultural insurance."

Increasingly useful work is being done by the Agricultural and General Co-operative Insurance Society; and "smaller local insurance societies or 'clubs' enable their members to insure economically their horses, cows, and pigs, by co-operating with one another."

Letting of Land. *Object F:* "To acquire land and sublet it to members in small holdings or allotments."

A number of societies have been formed to work under the Small Holdings and Allotments Act (1908), but here again the Board of Agriculture has shown considerable activity, and the special local work has been undertaken by county officers. Small holdings, at least those of agricultural nature, are pretty certain to be a dismal failure unless they can be grouped and managed on co-operative lines, each such group being controlled by a representative committee. It is only in this way that buying and selling can be conducted to advantage, the more expensive agricultural machinery employed, the dreary country winter enlivened, and the children of the small-holders secure the chance of suitable education.

Credit Societies. *Object G:* "To establish Agricultural Credit Societies."

Larger men can easily obtain money advances, while smaller cultivators, who need such advances more, are unable to do so. In other words, Land Banks, on the lines of the Raiffeisen and Schulze-Delitsch Banks established in Prussia about the middle of last century, are a crying necessity, although a number of the more reputable ordinary banks are willing to act in this capacity. The small farmer or small-holder ought, for example, to be able to secure at a reasonable rate the money necessary for the production of a crop, offering as security the value of that crop when harvested. We hear no more of dire distress among small cultivators in the West of Ireland, and this is because pecuniary advances have been rendered available on the lines indicated. Help on sound business lines, not charity, is what is needed.

Work of the Board of Agriculture. Quite apart from the co-operative societies, there are many organisations which exist solely to help the farmer, and some of these will now be passed in review. Readers wishing for further details will do well to consult the "British Year-book of Agriculture" (Vinton & Co., 5s. net), which is a perfect mine of information.

The Board of Agriculture was established in 1889, taking over various duties until then performed by other departments. It is now also responsible for Fisheries, the Ordnance Survey, and the Royal Botanic Gardens at Kew, but with these activities we are, of course, not concerned in this article. To Sir Thomas Elliott, Permanent Secretary from 1892 to 1913, agriculture owes a large debt of gratitude, and his pioneer work has been the making of the Board. Four branches or divisions of the Board have to do with agriculture.

The Animals Division. This is concerned with certain notifiable diseases of animals, and by an elaborate official machinery keeps them more or less in control.

The Intelligence Division. This branch administers the Acts dealing with the sale of food and drugs, fertilisers and feeding stuffs, destructive insects and pests, and so on, and also plays an important part in furthering education and research in agriculture and forestry. It publishes a valuable monthly journal at a cheap rate, and also a series of important leaflets on a great variety of subjects. Anyone interested in agriculture can, by sending a shilling to the Secretary of the Board (Whitehall Place, S.W.), secure the first 200 leaflets bound in two volumes, and subsequent leaflets gratis, and can enter his name on the list of those who receive, also gratis, further issues. Postage need not be prepaid, so that at no expense, except the initial shilling, those who will may greatly benefit. Advice on all agricultural matters is freely given.

The Land Division. This is mainly concerned with small holdings and allotments, and with the new Live Stock Improvement Scheme, under which work provincial live-stock officers, whose duty is to help farmers, especially small farmers, in every possible way.

The Statistical, Tithe, Commons, and Establishment Division. This branch collects and publishes a variety of important returns.

Similar duties are performed by the Board of Agriculture for Scotland and the Department of Agriculture and Technical Instruction for Ireland.

Provincial Schemes. An average English county maintains an expert staff, working under an agricultural organiser, and engaged in conducting classes for those on the land, and also in giving advice on routine matters. Arrangements are usually made whereby farmers can have analyses made of feeding stuffs, artificial manures, etc., at low prices. Some countries possess a farm institute or farm school for the benefit of those who are able to leave home for the purposes of receiving continuous instruction. England and Wales are now divided into twelve provinces, each with a Provincial Council for Agricultural Education, which correlates the activities of a group of counties, and is entrusted with directing—aided by a live-stock adviser—the Live Stock Improvement Scheme for its particular area. Each of the twelve provinces has a "collegiate centre," responsible for the higher forms of instruction, the giving of advice on difficult points, and the conduct of research. There are also certain institutions, notably the Rothamsted and Woburn Experimental Stations, which are engaged in research only, and have no local ties.

Scotland is divided into three provinces, for which Edinburgh, Glasgow, and Aberdeen Agricultural Colleges (and University Agricultural Departments) serve as centres, while Irish agriculture is organised by the central authority in Dublin.

Agricultural Societies and Institutions. These are exceedingly numerous, and promote a great variety of objects, many of local character. Three societies with wide aims, which hold important shows and give great advantages to their members by way of providing analyses and technical advice at a cheap rate, deserve special mention:

Bath and West and Southern Counties Society. Founded 1777. (Offices, 3, Pierrepont Street, Bath.)

Highland and Agricultural Society of Scotland. Founded 1784. (Offices, 3, George IV. Bridge, Edinburgh.)

Royal Agricultural Society of England. Founded 1838. (Offices, 16, Bedford Square, London, W.C.)

The Central and Associated Chambers of Agriculture. Founded 1865. (Offices, 1, Orchard Street, Westminster, S.W.)

The National Farmers' Union, founded 1908 (offices, 3, Wellington Street, Strand, London), endeavours "To combine the various Farmers' Unions in the country, with a view to the furtherance of the interests of farmers in a national sense." Only farmers in actual practice are admitted as members—a policy of somewhat doubtful wisdom.

We may fitly conclude this section by mentioning the Farmers' Club (2, Whitehall Court, London, S.W.), founded 1842, which not only provides a convenient centre for those connected with agriculture, but also has monthly meetings during the winter for the discussion of important agricultural questions.

Enough has now been said to indicate the possibilities embodied in agricultural co-operation. The whole thing is pithily summarised in the words of Mr. Nugent Harris, the eminently capable and inspiringly enthusiastic general secretary of the A.O.S.: "Our farmers must organise; there lies the future of English agriculture." J. R. AINSWORTH-DAVIS

THE EDUCATOR GUIDE TO KNOWLEDGE

A BIBLIOGRAPHY OF THOUSANDS OF BOOKS ON ALL SUBJECTS

If anybody would make me the greatest king that ever lived, with palaces and gardens, and fine dinners, and wines and coaches, and beautiful clothes, and hundreds of servants, on condition that I would not read books, I would not be a king—I would rather be a poor man in a garret with plenty of books than a king who did not love reading.

LORD MACAULAY

KNOWLEDGE grows from more to more, and the library of the busy man, however he may love books and buy them, cannot keep pace with it. Again and again we find ourselves wondering if there is a book on this subject or on that, and, if so, how we can get it. This supplement to the SELF-EDUCATOR is an attempt to meet this need.

IT does not claim to be complete; books pour out from the press so fast, and some pass out of print and are forgotten so soon, that no list can ever be complete. But at least it may be claimed to be the widest list of books ever published at so low a price, and perhaps it may claim to be as complete a list of its kind as has ever been brought within the reach of the general public. In some respects, too, it may be said to be unique; it is doubtful if there is to be found anywhere, for example, a more useful or more comprehensive chronology of English Literature, or a more helpful list of Anthologies, than will be found in these pages.

EVERY effort has been made to guard the bibliography from error, but with lists of thousands of books, issued by so many publishers in so many parts of the kingdom, it is beyond human hope that such a work can be perfect. Even the price of books is not always simple, for one book may be published in several ways at varying prices, or may have several volumes, all at different prices; and the discount system, one of the greatest absurdities ever born of foolishness, provides further confusion and complication.

IF it were possible to produce a work of this kind slowly, and with no regard for the cost of it, it would be possible to produce a work of which an editor might well be proud; but even a book, the greatest monument of human achievement on the earth, must be a commercial thing, and it has been found impossible here to be precise and definite on all points. It is not possible, for example, to indicate in all cases whether prices are net or not, and the prices are given here without this indication, on the ground that it is worth while indicating *the maximum price*, even though the actual price may be threepence in the shilling less. It is a sound rule to work upon that all books not over a shilling are published net, and that most books on serious subjects are also net, especially most technical books.

IN the few cases where neither publishers nor prices are given here the books are easily available from various sources; in some other cases, as in the Chronology of English Literature, prices are often not mentioned because the mention of the book in the chronology is secondary, the main reference to the work appearing elsewhere in the bibliography. A few out-of-print books have been included in the list because they may be valuable to students, and as a rule these books can be obtained from good libraries, but the general aim has been to confine the list to books that are readily available; and any bookseller can obtain probably ninety-nine books in a hundred in this list from the information contained in these pages.

LET KNOWLEDGE GROW FROM MORE TO MORE

THE COVER OF THE SELF EDUCATOR AS IT APPEARED IN FORTNIGHTLY PARTS

4000 BOOKS ON ALL SUBJECTS

A Bibliographical Companion to the Self-Educator

Nearly all these books, unless otherwise indicated, are readily available. The few out-of-print books included can be had from libraries.

The prices given are the maximum prices. On many books there will be a discount of threepence in the shilling, though this is not always stated.

Nearly all shilling books, and most technical books, are published net.

The subjects are grouped, generally, on the lines of the scheme of the Self-Educator.

Where the title and author only are given, the work is easily obtainable in various editions.

GEOGRAPHY

Embracing Physical, Political, and Commercial Geography.

The History section should also be consulted for books on countries

Geography. By J. W. Gregory. 305 pages. Illustrated. Blackie .. .. .. 6s. net
This book, by the Professor of Geology in Glasgow University, gives the most important facts concerning the structural geography of the earth, and the evolution of our present continents from older lands. The use of geological terms is avoided, but the geological horizons are defined and occasionally referred to. A delightful book for schools.

Elementary Lessons in Physical Geography. By Sir A. Geikie. 363 pages. Macmillan .. 4s. 6d.
A simple but systematic and interesting description of the familiar features of the surface of the earth. The earth as a planet; the air and its properties; the sea—its movements and offices; the land, and the distribution of the various forms of life.

Modern Geography. By Marion I. Newbigin. 248 pages. Williams & Norgate .. .. .. 1s.
Miss Newbigin, who has also done good work as a zoologist (see books on Animal Life), studies in this volume the leading questions of physical, biological, and sociological geography. It is an admirable piece of work, and contains a good bibliography.

The Earth: its Shape, Size, Weight, and Spin. By J. H. Poynting. Cambridge Univ. Press. 1s. net
Professor Poynting here explains, simply and without mathematical detail, how the shape and size of the earth have been determined, how its mass has been measured, and how we know that it rotates so as to be an almost perfect timekeeper. He also gives some account of the tidal action which reduces the earth's spin.

The Earth: Its Life and Death. By Alphonse Berget. Putnam .. .. .. 7s. net
A fine little book on an enthralling theme, telling the story of what is known of the birth and age of the earth, its form, magnitude, and mass, its everlasting movements, the force of gravity, the atmosphere, the "attack and the defence of the continents," and the earth's "Old Age and Death." The author asks the question whether the earth lives as things found on its surface live, and seeks to answer it.

The Romance of the Mighty Deep. By Agnes Giberne. 290 pages. Illustrated. Seeley. 5s.
A popular account of the ocean and the laws by which it is ruled, of its wonderful powers, and its strange inhabitants.

The Depths of the Ocean. By Sir John Murray and Dr. Johan Hjort. Illustrated. Macmillan. 28s. net.
A general account of the new science of the deep seas, based largely upon a recent voyage of exploration in the North Atlantic. Contains a sketch of the investigations of the "Challenger" and other expeditions; describes the depths and deposits of the ocean; its plant life; the deep-sea fishes, and general biology.

Modern Meteorology. By Frank Waldo. 460 pages. Illustrated. Walter Scott .. .. 3s. 6d.
An outline of the growth of the science of the weather, well worth bringing up to date in view of the considerable advances made by meteorologists since the book was written—in 1893.

Science of the Sea. Prepared by the "Challenger" Society. 452 pages. Illus. John Murray. 6s. net
An excellent handbook of practical oceanography for travellers, sailors, and yachtsmen, and admirable for the general reader. Gives the results of modern discoveries regarding the life and conditions of the deep seas—a new science established during the "Challenger" expedition. The various chapters are written by men of high authority.

The Alps in Nature and History. By W. A. B. Coolidge. 440 pages. Illus. Methuen. 7s. 6d. net
Offers the reader an account of the most interesting features presented by the Alps, based on the personal experience of over forty years' wanderings through every district of the great chain. The mountains are looked at from the physical side first; then the human history of the heights is told.

The Control of the Tropics. By Benjamin Kidd. 101 pages. Macmillan .. .. 3s.
The inheritance of the tropics is regarded as the great object of international rivalry in the future. The author denies that coloured races, left to themselves, possess the qualities for the development of the rich resources of the lands they have inherited; and holds that Europeans will realise that the tropics must be ruled from the temperate regions.

Descriptive Meteorology. By W. L. Moore. 344 pages. Illustrated. Appleton .. .. 12s. 6d.
A study of the known forms of energy that reach the earth from the sun, and of those parts of the earth that absorb, radiate, conduct, and reflect heat. A general introduction to the modern science of the weather.

Climate and Weather. By H. N. Dickson. 252 pages. Williams & Norgate .. .. 1s.
An excellent study of the atmosphere, illustrated by maps and diagrams; the influence of land and sea; the various climatic regions; climate and vegetation, and climate and man.

Sounding the Ocean of Air. By A. Lawrence Rotch. Illustrated. S.P.C.K. .. .. 2s. 6d. net
The kite and balloon researches carried out by Mr. Rotch, Director of the Blue Hill Meteorological Observatory, in the United States, have long been famous in the history of meteorology. The progress of aeronautics makes it essential that the movements of the upper air, now so little understood, should be fully investigated, and no better introduction to the study could be obtained than that given in this book.

Climate. By Robert de Courcy Ward. 372 pages. Illustrated. John Murray. .. .. 6s. net
A broad treatment of the question of climate, which, while not competing with meteorological textbooks, conveys special information in an interesting way, so that the book can be read by an intelligent person who has had no special training in meteorology.

The Ocean of Air. By Agnes Giberne. 334 pages. Illustrated. Seeley .. .. .. 5s.
An excellent account of meteorology for beginners. Very readable; any child over twelve would delight in it and learn much from it.

The Atmosphere. By A. J. Berry. 146 pages. Illustrated. Cambridge University Press. 1s. net
The history of the discovery of the properties of the constituents of the air is here told in an interesting way. The author has restricted himself to chemical and physical phenomena, and has omitted meteorology. The composition of the atmosphere at different heights is discussed, and also the probable atmospheres of earlier periods. The book is quite up to date, and includes reference to atmospheric radio-activity.

The Atmosphere. By E. J. Houston. 326 pages. Illustrated. Chambers .. .. 2s. 6d.
The book tells of the height and composition of the atmosphere, of sound-waves and echoes, of climate and weather-prediction, of the various kinds of storms, and of heat and light as far as they are involved in the science of the air.

Forecasting Weather. By W. N. Shaw. 380 pages. Illustrated. Constable .. .. 12s. 6d. net
The result of eleven years' experience in weather forecasting, by the Director of the British Meteorological Office. Explains the way in which synoptic charts are made, and how they are used in foretelling weather conditions. Chapters on gales and storm warnings, land and sea fogs, night frosts, colliery warnings, and forecasts for airmen.

The Aurora Borealis. By Alfred Angot. 264 pages. Illustrated. Kegan Paul .. .. 5s.
A sketch of the history of the subject, followed by an account of the forms of the Polar aurora; a description of its physical characters, and its extent, position, and frequency. The concluding chapters are concerned with the connection between the aurora and weather conditions, and with the magnetism of the earth, and the theory of its origin. Written in a clear way.

Discovery of the Source of the Nile. By John H. Speke. 477 pages. Dent .. .. 1s. net
Published in 1863, in the author's thirty-seventh year, this "Journal of the Discovery of the Source of the Nile" gives a vast mass of facts about the interior of Africa, and its peoples, animals, and plants, and is very readable. Though Speke's conclusions were doubted at the time, they have been proved correct.

Tropical Africa. By Henry Drummond. 242 pages. Illustrated. Hodder & Stoughton .. 3s. 6d.
One of the travel books that becomes literature through the freshness of the traveller's sight, and his power of investing whatever he writes with an incommunicable charm.

Island Life. By Alfred Russel Wallace. 584 pages. Illustrated. Macmillan .. .. .. 7s. 6d.
A most delightful and masterly study of the phenomena and cause of insular floras and faunas, with a revision and attempted solution of the problem of geological climates. The author is convinced that the distribution of the various species and groups of living things over the earth's surface, and their aggregation in definite assemblages in certain areas, is the direct result and outcome of a complex set of causes, biological and physical. These causes are clearly expounded.

Travels on the Amazon and Rio Negro. By Alfred Russel Wallace. 363 pages. Ward, Lock. 1s. net
Dr. Russel Wallace spent the four years 1848 to 1852 on the Amazon, being attracted thereto by Edwards's 'Travels on the Amazon." He has here recorded his experiences and observations of the native tribes, and also on the climate, geology, and natural history of the region.

The Opening Up of Africa. By Sir H. H. Johnston. 254 pages. Williams & Norgate .. .. 1s.
This excellent little historical summary of the development of the Dark Continent is well illustrated with maps. Many readers will be surprised to find how much was known of Africa before modern times. The work of Greeks, Romans, Moslems, Portuguese, and Dutch forms a story of absorbing interest.

Polar Exploration. By William S. Bruce. 254 pages. Williams & Norgate .. .. 1s.
Mr. Bruce, who has himself explored in the Arctic and Antarctic regions, and directs the Scottish Oceanographical Laboratory, Edinburgh, here deals not with the history of Polar adventure, but with the physical and biological conditions of Polar regions. Chapters are devoted to land ice, sea ice, plant and animal life, meteorology, aurora, magnetism, and other aspects of Polar geography.

Voyage of the "Beagle." By Charles Darwin. Darwin himself said: "The voyage of the 'Beagle' has been by far the most important event in my life, and has determined my whole career." Not only does it form an introduction, in spirit, to scientific study, but it is one of the most readable books of travel.

Realm of Nature. By Dr. H. R. Mill. Murray. 5s.
The object of this outline of physiography is to explain the methods by which our knowledge of Nature has been acquired and is being daily enlarged. To this end the interrelations of the various special sciences are shown, and the unity of science is suggested. A very valuable work, excellently illustrated by maps.

Conditions of Life in the Sea. By James Johnstone. Cambridge University Press .. .. 9s. net
An account of the main results of modern quantitative marine biological investigations, and the related results of hydrography and oceanography. The writer is attached to the Fisheries Laboratory of the University of Liverpool. He claims that his book is a summary of researches not yet presented adequately to English readers. It shows how, according to the latest investigations, the sea supports life in enormous quantities. Intensely interesting and, to most readers, original.

The Resources of the Sea. By Dr. W. C. McIntosh. Cambridge University Press .. .. 15s. net
The author puts into this book the results of certain critical tests of the effects of trawling. The general conclusion is that the allegations respecting the destruction caused by trawling are unfounded, and that Nature satisfactorily wards off man's attack, whatever form it takes. In short, the resources of the sea are practically inexhaustible. An interesting and able book.

PRICES OF BOOKS

In all cases the prices in this list are the maximum prices, and in many cases, whether indicated or not, there may be a discount of threepence in the shilling. Almost invariably shilling books, and nearly all technical works, are net.

ARTS AND CRAFTS

Embracing the History and Practice of Art and Its Varied Applications

History of Modern Painting. By Richard Muther. 4 vols. Dent .. .. 63s.
An attempt to show how painting has expressed the mind of the period in which it was produced. Profusely illustrated in black-and-white and colours.

Schools of Painting. By Mary Innes. Methuen. 5s. net
A very useful book, giving a description of the distinctive features of the works of groups of artists in different ages and lands, with brief biographies.

Outlines of the History of Art. By W. Lubke. 2 vols. Smith, Elder .. .. .. 36s. net
A standard work that has been thoroughly revised and brought up to date. Copiously illustrated.

Elementary History of Art, Architecture, Sculpture, and Painting. By Mrs. Arthur Bell. Low. 10s. 6d.
An excellent compendious general sketch of art from ancient to modern times.

A History of Art. By G. Carotti. 2 vols. Duckworth .. .. 5s. per vol.
This fine history of art by an Italian critic is in course of publication, under the English revision of Mrs. Arthur Strong. It is profusely illustrated, the first volume having 500 reproductions.

Bryan's Dictionary of Painters and Engravers. 5 vols. Bell .. .. 105s. net
A well-known comprehensive survey of art through biography. Encyclopædic in character.

Apollo. By S. Reinach. Heinemann .. 6s. net
A profusely illustrated catalogue of artistry, with brief biographies of artists. Contains an enormous amount of compressed information.

History of Painting. By Haldane Macfall. 8 vols. Jack .. .. 100s. net
A fine work, from both the literary and artistic points of view. It illustrates, through 200 plates and lucid criticism, the artistic genius of Europe.

A History of Ancient and Mediæval Architecture. By James Fergusson. 2 vols. John Murray. 56s.
This is the standard work on architecture, ancient, modern, and national. It has been carefully revised and is profusely illustrated.

History of the Modern Styles of Architecture. By James Fergusson. 2 vols. John Murray. 28s.
A continuation of Fergusson's great work, brought up to date, completing his survey of architecture.

A History of Architecture. By B. and B. F. Fletcher. Batsford .. .. 21s. net
A general survey, comprehensive and able, on more popular lines than the great work of Fergusson.

Sacred and Legendary Art. By Mrs. Jameson. Longmans .. .. 20s. net
One of the absolutely indispensable books, if the thoughts in the minds of the great early artists of Italy are to be understood. It shows the imaginative material on which the great artists worked.

The New Library of Art. Seeley .. 6s. net
A well-selected series of practical handbooks on various phases of art, by well-chosen writers.

The Principles of Greek Art. By Percy Gardner. Macmillan .. .. 10s. net
An examination of the principles of Greek art, to show their bearings on Greek literature.

Masters of Painting. Duckworth .. 3s. 6d. net
Six handsome volumes, with illustrations. The painters included are Raphael, Botticelli, G. F. Watts, Leonardo da Vinci, Holbein, and Rossetti.

The Library of Art. Duckworth .. .. 5s. net
A very valuable series, consisting of fourteen monographs on painters and sculptors, and eleven books on schools of painting as the characteristics of certain art periods. The writers are all competent.

A Popular Library of Art. Duckworth .. 2s. net
Twenty-one volumes—eighteen of them personal, and three on schools—by capable critics, describing Italian, English, French, and Flemish artists.

British Artists Series. Bell .. .. 3s. 6d. net
Six volumes, the subjects being the pre-Raphaelite painters, Burne-Jones, Rossetti, Gainsborough, Morland, and Turner.

Newnes' Library of Art. Newnes .. 3s. 6d. net
Finely illustrated volumes on painters of all nations.

The Art Galleries of Europe. Bell .. 6s. net
A useful series that covered nearly all the chief art galleries, but is now out of the publishers' catalogue except so far as the National Gallery and the Vatican are concerned.

Masterpieces in Colour. Jack. 1s. 6d. net each
Forty-eight monographs by competent critics, each book containing eight coloured pictures. The most representative series of the kind.

Great Engravers. Heinemann .. .. 2s. 6d. net
A dozen handsome books, each containing 64 illustrations. The subjects are Bartolozzi, Albrecht Dürer, Fragonard, Goya, Holbein, Hogarth, Mantegna, Marcantonio, John Raphael Smith, Rembrandt, Vandyck, and Watteau and Boucher.

Classics of Art. Methuen. Various prices, from 25s. net to 10s. 6d. net
Sixteen volumes of finely illustrated art criticism, by critics of international repute.

Illustrated Handbooks of Art. S.P.C.K. 2s. 6d. net
Nine volumes on schools of art and national characteristics, covering painting, architecture, and sculpture, under the editorship of Sir E. J. Poynter and Professor T. Roger Smith.

Great Masters in Painting and Sculpture. Bell. 3s. 6d.
Thirty-one illustrated monographs of the great artists of all times and lands, edited by Dr. G. C. Williamson. A most valuable series.

Gowans' Art Books. Many volumes. Gowans & Gray .. .. 1s. net per vol.
A marvellously cheap series. Each volume of the fifty-five published contains sixty photographs of the masterpieces of one of the great artists—Italian, Flemish, French, Spanish, or English.

Little Books on Art. 31 vols. Methuen, 2s. 6d. net.
A very useful and attractive series of books, dealing not only with individual painters and sculptors of all nations, but also with special art subjects, such as bookplates, enamels, manuscripts, and miniatures.

Six Centuries of Painting. By Randall Davies. Jack .. .. 10s. 6d. net
An amazing abundance of information and reproduced colouring. The painters are classified in Tuscan, Venetian, Spanish, Flemish, Dutch, German, French, and English schools, with a special chapter on the art of the nineteenth century. Fifty plates in colour illustrate the text. The text is chatty, but also judicial.

The Childhood of Art; or, the Ascent of Man. By H. G. Spearing. Ilustrated. Kegan Paul. 21s. net
A clear and interesting survey of human art, from the paintings of the primitive cave-men to the finest works of the Greeks, all interpreted as documents revealing the varying fortunes of man in his struggle for intellectual power and moral balance. The value of the book is enhanced by nearly 500 illustrations.

Progress of Art in the Nineteenth Century. By William and Elizabeth A. Sharp. Chambers. 5s. net. A masterly review of English, American, and Continental art, as developed during the nineteenth century. William Sharp was himself an artist in every fibre of his nature.

Art and Letters Library. Chatto & Windus. 7s. 6d. Seven volumes of stories of Italian, Flemish, English, French, Spanish, and German artists, with many coloured and half-tone plates.

Connoisseur's Library. Methuen .. ..25s. net Fifteen volumes, covering artistic work other than pictures and sculpture in marble. Handsome in style and capably presented. The subjects are English coloured books, English furniture, etchings, enamels, fine books, goldsmith's work, illuminated manuscripts, ivories, jewellery, mezzotints, miniatures, porcelain, seals, glass, and wood sculpture.

Ars Una—Species Mille. Heinemann .. 6s. net Six books dealing with the art of the British Isles, Spanish Peninsula, France, Egypt, Northern Italy, and Flanders. All the writers are men in official positions in the world of art.

Art Books for Students

DRAWING

Elements of Drawing. By John Ruskin. Illustrated. (Dent.) 1s.

The Practice and Science of Drawing. By Harold Speed. (Seeley.) 6s. net.

Human Anatomy for Art Students. By Sir Alfred Fripp and Ralph Thompson. (Seeley.) 7s. 6d. net.

The Art of Illustration. By Henry Blackburn. (W. H. Allen & Co.) 7s. 6d.

Modern Illustration. By Joseph Pennell. (Bell.) 7s. 6d.

Figure Drawing. By R. G. Hatton. (Chapman & Hall.) 7s. 6d.

Figure Composition. By R. G. Hatton. (Chapman & Hall.) 7s. 6d. net.

Nature's Laws and the Making of Pictures. By W. L. Wyllie, R.A. (Arnold.) 15s. net.

Light and Water. By Sir Montague Pollock. (Bell.) 10s. 6d. net.

Etching: A Practical Treatise. By Earl H. Reed. (Putnams.) 10s. 6d. net.

The Human Figure. By John H. Vanderpoel. (Batsford.) 8s. 6d. net.

The Theory and Practice of Perspective. By G. A. Storey, R.A. (Clarendon Press.) 10s. net.

PAINTING

The Practice of Oil Painting. By Solomon J. Solomon, R.A. (Seeley.) 6s. net.

Six Lectures on Painting, delivered to the Students of the Royal Academy. By George Clausen, R.A. (Methuen.) 3s. 6d.

Landscape Painting in Oil Colours. By Sir Alfred East, R.A. (Cassell.) 10s. 6d. net.

Landscape Painting in Water Colour. By J. MacWhirter, R.A. (Cassell.) 5s.

Marine Painting in Water Colour. By W. L. Wyllie, R.A. (Cassell.) 5s.

The Chemistry of Paints and Painting. By Sir. A. H. Church. (Seeley.) 6s.

Materials of the Painter's Craft. By A. P. Laurie, D.Sc. (Foulis.) 6s. net.

The Technique of Painting. By Chas. Moreau-Vauthier. (Heinemann.) 10s. 6d. net.

The Pigments and Mediums of the Old Masters. By A. P. Laurie, D.Sc. (Macmillan.) 8s. 6d. net.

Chevreul on Colour. Translated by C. Martel. (Bell.) 7s. 6d.

Leonardo da Vinci's Treatise on Painting. Translated by J. F. Rigaud, R.A. (Bell.) 5s.

The Practice of Water Colour Painting. By A. L. Baldry. (Macmillan.) 12s. net.

DESIGN

Bases of Design. By Walter Crane. (Bell.) 6s. net.

Line and Form. By Walter Crane. (Bell.) 6s. net.

Nature and Ornament. By Lewis F. Day. (Batsford.) 12s. 6d.

A Handbook of Ornament. By F. S. Meyer. Revised by Hugh Stannus. 3000 illustrations. (Batsford.) 12s. 6d.

The Principles of Design. By G. Woolliscroft Rhead. (Batsford.) 7s. 6d. net.

Modern Practical Design. By G. Woolliscroft Rhead. (Batsford.) 7s. 6d. net.

Treatment of Drapery in Art. By G. W. Rhead. (Bell.) 6s. net.

Heraldry for Craftsmen and Designers. By W. H. St. John Hope. (John Hogg.) 7s. 6d. net.

Complete Guide to Heraldry. By Arthur Charles Fox-Davies. (Jack.) 10s. 6d. net.

Manuscript and Inscription Letters for Schools and Classes. By E. Johnston. (John Hogg.) 3s. 6d. net.

Writing, Illuminating, and Lettering. By Edward Johnston. (John Hogg.) 6s. 6d. net.

Embroidery and Tapestry Weaving. By Mrs. A. H. Christie. (John Hogg.) 6s. net.

Japanese Encyclopædia for Design:

Book I. Containing over 1500 engraved, curious, and ingenious Geometric Patterns of Circles, Medallions, etc., with conventional details of Plants, Birds, Fans, Animals, etc.

Book II. Containing over 6000 Original Designs for Diaper Ornament, with Miniature Picturesque Sketches. (Batsford.) 2s. each vol.

Dress Designs. By Talbot Hughes. (John Hogg.) 7s. 6d. net.

SCULPTURE

Modelling and Sculpture. By A. Toft. (Seeley.) 6s. net.

Modelling: A Guide for Teachers and Students. By E. Lanteri. (Chapman & Hall.) 3 vols. 15s. each.

Talks on Art with Rodin. By Paul Gsell. (Hodder & Stoughton.) 16s.

The Sculpture and Art Student's Guide to the Proportions of the Human Figure. By Dr. G. Schadow. (Chapman & Hall.) 10s. 6d.

WOOD-CARVING

Practical Wood-carving. By Eleanor Rowe. (Batsford.) 7s. 6d. net.

Wood-carving. By Geo. Jack. (John Hogg.) 5s.

Ecclesiastical Woodwork. By T. Talbot Bury. (Batsford.) 8s. 6d. net.

Wood-carving. By C. G. Leyland. (Whittaker.) 4s.

Hints on Chip-carving. By Eleanor Rowe. (Batsford.) 1s. net.

METALWORK

Silverwork and Jewellery. By H. Wilson. (John Hogg.) 6s. 6d. net.

A Handbook of Art Smithing. By F. S. Meyer. (Batsford.) 5s. net.

Handcraft in Wood and Metalwork. By John Hooper and A. J. Shirley. (Batsford.) 7s. 6d. net.

Decorative Wrought Ironwork of 17th and 18th Centuries. 16 large lithographic plates, and 70 English examples of Gates, Screens, Grilles, Panels, Balustrading, etc. Measured and drawn by D. J. Ebbetts. (Batsford.) 10s. net.

The Armourer and His Craft. By Charles ffoulkes. (Methuen.) 42s. net.

Decorative Ironwork from XI. to XVIII. Centuries. By Charles ffoulkes. (Methuen.) 42s. net.
Repoussé Work for Amateurs. By L. L. Haslope. (Upcott Gill.) 1s. net.
Repoussé Metalwork. By A. C. Horth. (Methuen.) 2s. 6d.

General Works on Art

Modern Painters. (Student's edition.) By John Ruskin. 6 vols. (G. Allen.) 28s. 6d.
Discourses on Art. By Sir Joshua Reynolds. (Dent.) 1s. net.
Fine Arts. By G. Baldwin Brown. (Murray.) 6s. net.
Ideals in Art. By Walter Crane. (Bell.) 10s. 6d. net.
Lectures on Art. By John Ruskin. (Allen.) 3s. 6d.
Progress of Art in the Nineteenth Century. By Wm. Sharp. (Chambers.) 5s. net.
A Short History of Art. By F. C. Turner. (G Allen.) 3s. 6d.
How to Look at Pictures. By R. C. Witt. (Bell.) 5s. net.
A Text Book of the History of Painting. By J. C. Van Dyke. (Longmans.) 6s.
A Concise History of Painting. By Mrs. C. Heaton. (Bell,) 5s.
Impressionist Painting. By Wynford Dewhurst. (Newnes.) 25s. net.
Lectures on Painting. By George Clausen. (Methuen.) 6s net.

PHYSIOLOGY

The Human Mechanism. By Theodore Hough and William T. Sedgwick. Illustrated. Ginn. 8s. 6d.
The physiology of the human body is fully treated in its relation to hygiene, sanitation, and the general regulation of its surroundings. A scientific and practical work.

The Circulation of the Blood. By William Harvey.
This famous work, which revolutionised medical science, was printed in 1628 in Latin; the present translation was made 220 years later.

Lessons in Elementary Physiology. By Thomas H. Huxley. Macmillan. .. .. .. 4s. 6d.
A short, clear, businesslike description of the organs and build and activities of the human body. Surveys the general field of anatomical science, and deals with the main facts of the processes of life.

A Textbook of Physiology. By Sir Michael Foster. Four vols. Macmillan .. .. .. 39s.
A classical work on the structure and functions of the body, by the famous leader of the Cambridge School of Physiology. It covers the entire field, and, though clearly and methodically written, it is rather too large for popular reading, though extremely useful for general reference and study.

Manual of Human Physiology. By Leonard Hill. 496 pages. Illustrated. Arnold .. .. 6s.
Designed to give the general reader some insight into the wonderful complexity of structure and function which, taken together, compose a living man. Technical terms avoided as far as possible.

Principles of Physiology. By J. G. McKendrick. 242 pages. Williams & Norgate .. 1s. net
This popular review of the principles of physiology, by a well-known authority who was lately professor in Glasgow University, is designed for readers with no scientific training.

The Human Body. By Arthur Keith. 256 pages. Williams & Norgate .. .. .. 1s. net
This book, by an eminent member of the Royal College of Surgeons, treats of the history of the human body rather than of its structure and mechanism. The body and its senses are considered in relation to the problem of the antiquity and genealogy of man, and the author summarises our present knowledge.

Comparative Physiology. By Louis Agassiz. English translation by Thomas Wright. Bell .. .. 5s. An epitome of the leading principles of the science of zoology, in popular language, but treated scientifically. Though written in the middle of last century, this book still remains one of the best manuals of the subject.

A Handbook of Physiology. By W. D. Halliburton. Illustrated. John Murray .. .. 15s. net A student's textbook of the very highest quality, by the Professor of Physiology at King's College, London. The work has been tested by time, and its 700 illustration, including coloured plates, give it a double value.

General Physiology of Muscles and Nerves. By J. Rosenthal. 324 pages. Kegan Paul .. 5s. The first connected account of the general structure of muscles and nerves, a subject interesting to the specialist, the man of science, and the general reader of cultivated tastes.

The Natural History of Digestion. By A. L. Gillespie. 427 pages. Illustrated. Walter Scott .. 6s. A description of the general laws governing digestive processes in all living bodies—plants as well as animals. Prefaced by an account of ancient theories of digestion, and closing with an examination of stimulants and foods, the book in its leading chapters discusses every phase of digestion and the action of the digestive organs. Its appeal is made both to the student and the general reader.

The Growth of the Brain. By H. H. Donaldson. 365 pages. Illustrated. Walter Scott 3s. 6d. A scientific work for the parent and the teacher, showing the comparative insignificance of formal education. It is suggested that the powers of the nervous system are all-important to the welfare of the higher animals, and that it is necessary to search out their growth and changes. This the author has attempted.

The Brain and its Functions. By J. Luys. 327 pages. Kegan Paul .. .. 5s. In the first part the writer treats of the anatomy of the brain by new methods of investigation that he discovered. In the second part he deals with the general properties of the nervous elements, the evolution of memory, dreams, the genesis of personality, ideas and sense impressions. The book is thirty-two years old, but worth reading.

Deaf Mutism. By Dr. James Kerr Love. 369 pages. Illustrated. Maclehose .. .. .. 9s. net An important work on deaf-mutes, produced in answer to the need for a careful study of the subject from a medical point of view. Besides discussing fully the origin of the disability in speech and hearing, the work treats of the education of deaf-mutes, and surveys the various systems.

Colour-Blindness and Colour-Perception. By F. W. Edridge-Green. Kegan Paul .. .. 5s. Observations based on the examination of 116 colour-blind persons and numerous recorded cases. A practical book, based on work done for the Board of Trade. Attributes colour-blindness to diminution in the visual range, and gives instances of acquired colour-blindness. About one in five persons, according to the writer, has a diminished perception of colour, men being worse than women.

PRICES OF BOOKS

In all cases the prices in this list are the maximum prices, and in many cases, whether indicated or not, there may be a discount of threepence in the shilling. Almost invariably shilling books, and nearly all technical works, are net.

The Brain as an Organ of Mind. By H. Charlton Bastian. 708 pages. Illustrated. Kegan Paul. 5s. After discussing generally the uses and elements of a nervous system, Dr. Bastian considers the nervous system in invertebrates; then the brain of the vertebrates and intelligence in lower animals; and, lastly, brain and intelligence in man. He mentions that he has sought to embody in one book some details concerning all the roots from which the complex science of mind is derived, in order to show its many-sided origin.

HEALTH

See also under Bacteriology

The Hygiene of Mind. By Sir T. S. Clouston. 284 pages. Illustrated. Methuen .. .. 7s. 6d. net This book aims at giving in popular language some of the most important facts that have been ascertained with regard to the mind, and considers the conclusions from those facts in relation to mental betterment through physiological, psychological, and medical means.

Control of Body and Mind. By Frances Gulick Jewett. 269 pages. Illustrated. Ginn. 2s. 6d. Emphasis is laid on the care and cultivation of the special senses; on the relation of health to efficiency, mental clearness, and memory; on the influence which worry, fear, anger, hope, and joy exert over circulation, respiration, and digestion; on the power which alcohol and narcotics have to damage the nervous system and to destroy character.

Functional Nerve Diseases. By A. T. Schofield. 324 pages. Methuen .. .. 7s. 6d. net Deals with the nervous disorders that are "sweeping over civilised society like a plague." Attributes them to the perpetual hustle and competition of modern life, and regards them as mental phenomena rather than physical. Seeing that the mind takes a large share in the causation of many of these nerve diseases, the author argues that the mind should play a considerable part in their cure.

Responsibility in Mental Disease. By Henry Maudsley. 313 pages. Kegan Paul .. .. .. 5s. Discusses how insane persons differ from sane persons; the insane temperament; kinship between madness and various diseases; the different forms of mental derangement; the law in regard to insanity, and the prevention of insanity. A standard work by a high authority on the subject.

Hygiene of Nerves and Mind in Health and Disease. By August Forel. 343 pages. John Murray. 6s. net As a psychologist, especially in the fields of instinct and hypnotism, Professor Forel has a world-wide reputation. His position as director of a Swiss asylum has given him abundant opportunities for the investigation of mental disease. The results are seen in this work. Dr. Forel hold that hygienic rules whose grounds are not understood may easily do harm. Here he tries to give such a conception of popular hygiene as will enable an intelligent layman, with a fair education, to govern his life so as to avoid diseases as far as possible for himself, his fellow-men, and his offspring.

The Dawn of the Health Age. By Benjamin Moore, M.A., D.Sc. Churchill .. .. .. 3s. 6d. net An admirable and convincing volume, intended to demonstrate the necessity for entirely remodelling the present system of medical service in the interests of the whole community. The author pleads eloquently for the establishment of a national medical service, which, he maintains, is the only satisfactory service for rich and poor alike, both being attacked equally by one set of disease agents.

The Health of the School Child. By W. Leslie Mackenzie. 127 pages. Methuen .. 2s. 6d.
A useful study of what may be done through the medical inspection of school children. The experience of the author has been gained in Scotland, and he is also acquainted with German organisation of school inspection from a medical point of view. A most careful sketch of a most hopeful movement.

School Hygiene : the Laws of Health in Relation to School Life. By Arthur Newsholme and W. C. C. Pakes. 310 pages. Illustrated. Allen & Unwin. 3s.
Intended for teachers, school managers, and other persons interested in the health of school children. Deals with the site and surroundings, lighting and ventilating of schools, the diet, dress, physical education of scholars, and has valuable chapters on communicable diseases for the guidance of teachers.

Infancy. By T. N. Kelynack. Methodist Publishing Company .. .. 1s. net
A practical little handbook, by a well-known physician, giving advice to mothers and to those who are in charge of such institutions as schools for mothers, crêches, milk depots, etc. A brief statement of the laws relating to infant life and of the action of municipal bodies is included. The whole is in clear and simple language.

Adolescence. By G. Stanley Hall. Two vols. Appleton .. .. 31s. 6d. net
One of the most significant books of the present age, that has only just begun to reach the consciousness of thinkers and educationists in this country. Dr. Stanley Hall, who has great influence in American education, is the first writer to appreciate adequately the enormous importance of the period of adolescence, and to discuss it in all its phrases, comprising its relations to physiology, anthropology, sociology, sex, crime, religion, and education.

Health and Disease. By Leslie Mackenzie. 252 pages. Williams & Norgate .. .. .. 1s. net
Dr. Leslie Mackenzie, medical member of the Local Government Board for Scotland, discusses a wide range of health subjects, including death rates, infections, antitoxins, immunity, tuberculosis, plague, disease and destitution, the evolution of the health movement. Able, popular, and concise.

The Problem of Age, Growth, and Disease. By Charles Minot. 280 pages. John Murray. 6s. net
This book is based on lectures delivered at the Lowell Institute in 1907. It traces life through all its stages, from its inception to its apparent individual disappearance. Dr. Minot belongs to the school of scientists who hold that an agnostic position is the only possible and defensible one for a man who is loyal to the spirit of research, but he does not give the grounds for taking up this position. The work is of great but controversial interest. For example, the author ventures on the most astonishing statement that "few men after twenty-five are able to learn much."

Handbook of Practical Hygiene. By D. H. Bergey. 164 pages. Williams & Norgate .. 6s. 6d. net
A most convenient handbook for the guidance of students in the sanitary analysis of air, water, soil, and the principal food materials, and in testing the ventilation of buildings.

A Manual of Pathology. By Sidney Martin. Illustrated. John Murray .. .. .. 15s. net
A comprehensive survey of the science of general pathology, illustrated with micro-photographs, which has been declared "superior to any other work of the kind in the English language." Intended for students.

The New Hygiene. By Elie Metchnikoff. 104 pages. Heinemann .. .. 2s. 6d.
Three lectures delivered under the auspices of the Royal Institute of Public Health, with introduction by Sir E. Ray Lankester. They deal with the prevention of infectious diseases.

The Care of the Body. By F. Cavanagh. 292 pages. Methuen .. .. 7s. 6d. net
A discussion of the general principles and daily practice of health. Deals with length and conditions of sleep, cold and warm baths, exercise, fatigue and massage, the clothing, skin, hair, teeth, eyesight, and habits. A clearly written book on commonsense ways of life.

The Chemistry of Life and Health. By C. W. Kimmins. Illustrated. Methuen .. 2s. 6d.
This book is intended to give a concise and simple account of the various scientific laws and processes necessary to the proper understanding of the subject of hygiene. In it are described the chemical processes which affect the atmosphere; the structure of the body; the composition of water and of food substances. Ventilation, prevention of infection and of disease, and the proper cooking of food, are treated on a scientific basis.

Infection and Immunity. By George M. Sternberg. 293 pages. John Murray .. .. 6s. net
An attempt to study the main facts with reference to infection and immunity, with the practical object of indicating the measures necessary for the prevention of infectious diseases. The work is intended for non-medical readers, and technical terms are, as far as possible, avoided. Dr. Sternberg confines himself to what he regards as well-established facts, and does not enter upon questions raised by such remedies as "antitoxins" and German chemical specifics.

Sleep. By Marie de Manaceine. 341 pages. Illustrated. Walter Scott .. .. .. 3s. 6d.
A valuable consideration of the "physiology, pathology, hygiene, and psychology" of sleep, with a good bibliography, and interesting examples of dreams and complex personality.

Sleep and Sleeplessness. By Haydn Brown. 160 pages. Hutchinson .. .. .. 2s. 6d.
Very important advice on a little understood subject, to sufferers from insomnia. Will be extremely helpful in all such cases.

Milk and the Public Health. By W. G. Savage. 594 pages. Illustrated. Macmillan .. 10s. net
An attempt to measure and assess the dangers of milk, and show how they can either be removed or diminished. Deals with bacteriology of milk and human disease; the examination of milk, and public health control of the milk supply; education of the milk trade by the rejection of dirty milk; and the necessity for continual bacteriological examinations, because nothing can take their place.

Drugs and the Drug Habit. By H. Saintsbury. 307 pages. Illustrated. Methuen .. 7s. 6d. net
An eminent London physician discourses of drugs in their normal or medical use, and again in their habitual abuse by victims of unhealthy habits. Interesting and readable for those whom the subject attracts; specially valuable to medical students.

Pasteur and After Pasteur. By Stephen Paget. Black .. .. 3s. 6d. net
An outline of the life of Pasteur, with descriptions of the many means for the prevention and expulsion of disease which have been developed out of Pasteur's work. Statistics are given that should be known to all anti-vaccinationists.

Food and the Principles of Dietetics. By Robert Hutchison. 635 pages. Illustrated. Arnold. 16s. net
Designed for students and doctors, but likely to be interesting to any person desiring to acquire some knowledge of foods and the difficult problems of nutrition. Patent and proprietary foods are examined and discussed on their merits, and certain dietetic cures and systems are criticised. Written on the whole in plain English; a work of authority.

Air and Health. By R. C. Macfie. 340 pages. Methuen .. .. 7s. 6d. net
An able work, dealing with the physical and chemical properties of air, particularly with reference to health and disease. The physiology of respiration is considered in its practical bearings, and chapters are devoted to the questions of climate, dust, fogs, germs, epidemics, etc. The discussion of ventilation is interesting.

Alcohol and the Human Body. By Sir Victor Horsley and Mary D. Sturge. Macmillan .. .. 1s. net
A wonderful little book, constituting an armoury of unchallengeable facts as to the effects of alcohol on health. There is a chapter by Dr. Arthur Newsholme, Chief Medical Officer of the Local Government Board, dealing with the influence of alcohol on the national health. A book for all who wish to know the real truth about alcohol.

Alcoholism: a Chapter in Social Pathology. By W. C. Sullivan, M.D. Nisbet. ... ... 3s. 6d. net
Gives in a clear, concise form a summary of the main facts of the drink question, especially in regard to the connection of alcoholism with industrial conditions. Traces a fifth of the suicides of the country to constant intemperance, and three-fifths of the homicidal crime to the same cause. Holds that chronic intoxication is not due to convivial drinking, but to the use of alcohol as a stimulant to muscular work.

The Drink Problem of Today. Edited by T. N. Kelynack. 300 pages. Methuen .. 7s. 6d. net
A survey of the main problems of modern life from many points of view. All the writers speak with authority. Many points of interest are raised, and the individual contributors have not hesitated to express their views on matters on which a disagreement of opinion exists; but, throughout, a truly scientific presentation of the subject is attained.

The Conquest of Consumption. By A. Latham and C. H. Garland. 159 pages. Fisher Unwin. 1s. net
A résumé of the knowledge we have of the cause and prevention of consumption, with a sketch of a national scheme for preventing the spread of the malady, and providing anti-tuberculosis dispensaries. The only adequate remedy for consumption, in the view of the authors, is efficient sanitorium treatment.

Prevention of Tuberculosis. By Arthur Newsholme. 429 pages. Illustrated. Methuen .. 10s. 6d. net
A thorough study of the whole subject, with good bibliography. Its three parts deal respectively with the causation of tuberculosis; the means by which the mortality from this disease has already been reduced; and future preventive measures for the reduction and annihilation of tuberculosis.

The Alcohol Factor. By George Blaiklock. P. S. King .. .. 1s. net
Written for the National Temperance League, this publication deals with alcohol first in relation to the child, then to adolescents, and lastly to adults. The evidence is taken largely from reports, and proves alcohol injurious to physical, mental, and moral health, and economic well-being.

The Geographical Distribution of Disease. By Alfred Haviland. George Allen & Unwin.. 15s.
The author thinks he has discovered a close association of certain types of scenery with certain types of disease, and he seeks to point out where certain diseases thrive, and where they do not thrive, and to study the reason why. Thus, rheumatism should avoid valleys, cancer should avoid all clayey soils, and consumption should hide from the prevailing winds. By means of maps and arguments the author develops these views, for the profit of physician and patient alike.

Bacteria and Their Products. By Dr. G. Sims Woodhead. Walter Scott .. .. 3s. 6d.
Gives an account of the main facts of bacteriology, and the life-history of bacteria and allied organisms, with a discussion of the more important theories as to the part played by them in Nature's economy, especially in relation to the commoner fermentative, putrefactive, and disease processes. Diseases discussed include cholera, typhoid fever, tuberculosis, leprosy, anthrax, lockjaw, diphtheria, and hydrophobia. An admirable summary.

AGRICULTURE

Embracing Cultivation of the Earth, Poultry, Live-stock, Dairying, Forestry, Gardening.

The Natural History Section should also be consulted.

Agriculture. By William Somerville. 251 pages. Williams & Norgate .. .. .. 1s. net
An excellent handbook, by the Oxford Professor of Rural Economy, dealing with the formation, properties, and main types of soil; the amelioration of land; the principles of manuring, including all the different kinds of fertilisers; the rotation of crops, and seed. Bibliography.

Agriculture for Beginners. By C. W. Burkett, F. L. Stevens, and D. H. Hill. Ginn .. 3s. 6d.
The authors of this book believe in training children from an early age to love and understand the fundamental principles of farming. These principles are here presented in a simple and attractive manner, for the purpose of school-teaching of agriculture.

A First Book of Forestry. By Filbert Roth. 291 pages. Illustrated. Ginn .. .. 3s. 6d.
An attempt is being made in America to make the principles of forestry more widely understood in schools and country homes, and this book, by the Chief of the United States Division of Forestry, is well designed for this purpose.

Forestry for Woodmen. By C. O. Hanson. 222 pages. Illustrated. Clarendon Press. 5s. net
A thoroughly practical book on a much neglected subject. Mr. Hanson has a full knowledge of woodcraft. Taking Schlich's "Manual of Forestry" as his basis, he has produced a book which covers scientically the whole range of the woodman's work, in language easy to understand.

A Textbook of Agricultural Botany. By F. V. Theobald. 536 pages. Illustrated. Blackwood. 7s. 6d.
Written for students in agricultural colleges, and farmers. It considers primarily the life histories and habits of animals met with in farm and garden, particularly those which affect, for good or evil, the stock and crops of the cultivator of the soil.

Agricultural Geology. By J. E. Marr. 318 pages. Illustrated. Maps. Methuen .. .. .. 6s.
Prepared for students' reading for examinations in agriculture; but, in spite of its scholastic tone, interesting to anyone who loves the country-side.

Agricultural Zoology. By J. Ritzema Bos. Translated by J. R. Ainsworth-Davis. 312 pages. Illustrated. Methuen .. .. 3s. 6d.
Clear descriptions, well illustrated, of the members of the animal kingdom which are harmful or helpful to the farmer, with suggestions as to methods for getting rid of his foes. The book is intended for use in agricultural colleges, and also for the private use of the practical farmer.

Soil Fertility and Fertilisers. By J. E. Halligan. 397 pages. Illustrated. Williams & Norgate. 14s. 6d.
This treatise on fertilisers of all kinds is intended for the use of farmers, agricultural and horticultural students, manufacturers, and others. The language is as free from technical terms as it was possible to make it. Fertiliser formulas for various crops are given. A book of reference for the practical farmer and student rather than a book to read.

Our British Trees, and How to Know Them. By F. G. Heath. 492 pages. Illus. Hutchinson. 5s. net
An admirable pocket-manual, enabling the observer to identify all species. There are 250 excellent illustrations, chiefly from photographs.

The Principles of Horticulture. By Wilfred Mark Webb. 136 pages. Illustrated. Blackie. 2s. net
Intended to form an introduction to the theoretical side of horticulture, and written primarily for those engaged in its practice, and for the help of students for the Royal Horticultural Society's examination. Annotated diagrams are used to avoid long descriptions, and are admirably clear.

Rural Denmark and Its Lessons. By H. Rider Haggard. 325 pages. Longmans .. 3s. 6d.
An inspiriting examination of the causes of the remarkable prosperity of the small-holders and farmers of Denmark. Two or three far-seeing men managed to induce the Danish peasantry to co-operate in marketing their produce, with the result that they are now one of the most flourishing classes of men in Europe.

Queen-Rearing in England. By F. W. L. Sladen. 56 pages. Illustrated. Houlston .. .. 1s.
A pamphlet dealing with bees, not princesses. It is an excellent practical manual on the breeding of good queens.

Book of Poultry. By Lewis Wright. Revised and edited by S. H. Lewer. Cassell .. 21s. net
This famous standard work has been brought up to date in accordance with the latest poultry club standards. As an authority on the various breeds of fowls, ducks, geese, swans, turkeys, and the best methods of rearing, feeding, exhibiting, and marketing, the book is unequalled.

Our Friend the Horse. By F. T. Barton. 276 pages. Illustrated. Dean .. .. 6s.
A practical guide to all breeds of horses, English and foreign ponies, asses, and mules; to the anatomy of the horse; to conformation; teeth and age; stables and stable-management; foods and feeding; horsemanship and horse-training; diseases, castration, treatment in sickness, and to the buying and selling of horses. The whole is written in a clear, brief, and systematic style, very convenient for reference.

Plant Diseases. By Werner F. Bruck. English translation by J. R. Ainsworth-Davis. 152 pages. Illustrated. Blackie .. .. .. 2s. net
This excellent little treatise is of great practical use. It is distinguised from most other books on the same subject in that it treats chiefly of the effects upon the plant rather than of the character and life histories of pests.

Story of a Grain of Wheat. By W. C. Edgar. 195 pages. Illus. Hodder & Stoughton. 1s. net
A popular account of the wheat-berry and wheat-growing, especially of the great Canadian wheat-fields and their apparently exhaustless sources of food, including also the possibilities in Argentina and in the United States. The wheat-berry itself is analytically described, and the various processes of milling reviewed.

The Book of the Farm. Edited by James Macdonald. 3 vols. Blackwood .. .. 63s. net
A standard work, dealing exhaustively with every branch of agriculture, under the general headings of land and its equipment, farm crops, and live-stock. More than 700 illustrations.

The Food of Some British Wild Birds. By W. E. Collinge. Dulau .. .. 4s. net
An interesting study of the food of birds as shown by the contents of their crops after they have been killed. Farmers, market gardeners, and naturalists are alike concerned in its accusations and apologies. The writer is not too favourable to the birds.

The Development of British Forestry. By A. C. Forbes. Edward Arnold .. .. 10s. 6d. net
A general review of the whole problem of afforestation as it should appear to the landowner and the practical forester. The author holds that a re-adjustment between agriculture and forestry is necessary, and argues his case very cogently. A sound and suggestive book.

The New Earth. By W. S. Harwood. Macmillan. 7s. 6d. net
The sub-title describes this book, with truth, as "a recital of the triumphs of modern agriculture in America." The work done by men of whom Luther Burbank is the type is, as the author says, "of commanding economic importance" in a "tremendously practical realm." The book has a fascination fully commensurate with the importance of its subject, which is the growing, for the use of man, of much more food than could ever be hoped for from the same ground a few generations ago.

Physical Properties of Soil. By Robert Warington. Clarendon Press .. .. 6s.
The contents of this book were first made public in lectures at Oxford, the author being the Professor of Rural Economy. An attempt was made to show how soils have been studied experimentally, chiefly in America, their physical constitution determined largely, and the relations between the soil and water, heat, and the movements of salts examined. An admirable effort to interest cultivators of the soil in the materials they use.

The Fertility of the Soil. By E. J. Russell. Cambridge University Press .. .. .. 1s. net
This book is a reproduction, in the Cambridge Manual Series, of the substance of lecturettes, by the Director of the Rothamsted Experiment Station, on how the soil may be made and kept fertile. An excellent example of scientific lucidity.

The Forester. By John Nisbet. 2 vols. Blackwood .. .. 42s. net
A standard work on British forestry and arboriculture for landlords, land agents and foresters, by an expert scientist and writer. Splendidly illustrated.

The Elements of British Forestry. By John Nisbet. Blackwood .. .. 5s. 6d. net
A practical manual for forest apprentices and students in agricultural colleges and universities, by a highly competent writer. Many illustrations.

Farm and Garden Insects. By W. Somerville. (Macmillan.) 1s.
Text-book of Agricultural Zoology. By F. V. Theobald. (Blackwood.) 8s. 6d.
Diseases of Plants. By H. Marshall Ward. (S.P.C.K.) 2s. 6d.
Diseases of Cultivated Plants and Trees. By G. Massee. (Duckworth.) 7s. 6d.
Small-holder's Handbook. By W. M. Elkington. (Upcott Gill.) 3s. 6d. net.
The Book of the Rothamsted Experiments. By A. D. Hall. (Murray.) 10s. 6d. net.
Co-operation in Agriculture. By G. H. Powell. (Macmillan.) 6s. 6d. net.
Chemistry of the Farm. By R. Warington. (Vinton.) 2s. 6d.
Manual of Agricultural Chemistry. By H. Ingle. (Scott, Greenwood.) 7s. 6d. net.
Maize: Its History, Cultivation, Handling, and Uses. By J. Burtt-Davy. (Longmans.) 25s. net.
Book of the Potato. By T. W. Sanders. (Collingridge.) 2s. 6d. net.
Fertilisers and Manures. By A. D. Hall. (Murray.) 5s. net.
Artificial Manures. By G. Ville and Sir W. Crookes. (Longmans.) 10s. 6d. net.
Soil Conditions and Plant Growth. By E. J. Russell. (Longmans.) 5s. net.
Birds Useful and Birds Harmful. By O. Herman and J. A. Owen. (Manchester Univ. Press.) 6s.
The Food of some British Birds. By R. Newstead. (Board of Agriculture and Fisheries.) 4d. net.
Farm, Garden, and Birds: How to Protect Grain, Fruit, and Other Crops without Destruction of Bird Life. Royal Society for the Protection of Birds. (Witherby.) 1s.
Commercial Gardening. (Gresham Publishing Co.) 4 vols. £1 16s.
Culture of Vegetables and Flowers. By Sutton & Sons. (Simpkin, Marshall.) 5s.
New Creations in Plant Life. By W. S. Harwood. (Macmillan.) 7s. 6d. net.
Injurious and Useful Insects. By L. C. Miall. (Bell.) 3s. 6d.
Fruit Farming. By C. H. Hooper. (Lockwood Press.) 3s. 6d.
Chemistry of the Garden. By H. H. Cousins. (Macmillan.) 1s.
Fruit and Its Cultivation. By T. W. Sanders. (Collingridge.) 6s. net.
Practical Fruit Culture. By J. Cheal. (Bell.) 2s. 6d.
Vegetables and their Cultivation. By T. W. Sanders, (Collingridge.) 5s. net.
A Manual of Injurious Insects. By W. E. Collinge. (Midland Educational Co.) 12s. 6d. net.
Manual of Injurious Insects and Methods of Prevention. By E. A. Ormerod. (Simpkin, Marshall.) 5s.

Poultry

Poultry-keeping as an Industry for Farmers and Cottagers. By E. Brown. (Arnold.) 6s. net.
Poultry for Prizes and Profit. By J. Long and W. M. Elkington. (Upcott Gill.) 6s. net.
Races of Domestic Poultry. By E. Brown. (Arnold.) 6s. net.
Poultry Diseases and their Treatment. By B. F. Kaupp. (Baillière, Tindall & Cox.) 5s. net.

Live-stock

The Feeding of Crops and Stock. By A. D. Hall. (Murray.) 5s. net.
Farm Foods. By E. von Wolff. Translated by H. H. Cousins. (Gurney & Jackson.) 8s. 6d.
The Feeding of Animals. By W. H. Jordan. (Macmillan.) 6s. 6d. net.
The Book of the Goat. By H. S. Holmes Pegler. (Upcott Gill.) 6s. net.
The Goat: Its Use and Management. By J. T. Bird and T. W. Sanders. (Collingridge.) 1s. 6d.
Horses, Past and Present. By Sir W. Gilbey. (Vinton.) 2s.
The Horse: Its Origin and Development, combined with Stable Practice. By R. F. Meysey Thompson. (Arnold.) 15s. net.
Book of the Pig. By J. Long. (Upcott Gill.) 6s. 6d.
Pigs, Breeds, and Management. "Live-stock" Handbook No. 5. By Sanders Spencer and J. Wortley Axe. (Vinton.) 3s. 6d. net.
Sheep, their Management and Breeding. By J. H. Muir. (Collingridge.) 1s. net.

Dairying

Dairy Chemistry. By H. D. Richmond. (Griffin.) 15s.
Milk Analysis. By J. A. Wanklyn. (Kegan Paul.) 5s.
Milk: Its Nature and Composition. A Handbook on the Chemistry and Bacteriology of Milk, Butter, and Cheese. By C. M. Aikman. (Black.) 3s. 6d. net.
Cows, Cowhouses, and Milk. By G. Mayall. (Baillière, Tindall & Cox.) 2s. 6d. net.
Successful Dairy Work. By A. T. Matthews. (Rebman.) 2s. 6d. net.
Modern Dairy-farming. By H. L. Puxley. (Upcott Gill.) 3s. 6d. net.
The Book of Dairying. By W. Fleischmann. (Blackie.) 10s. 6d.
The Home Dairy and Its Management. By E. A. Maidment. (Simpkin, Marshall.) 3s. 6d.
Milk, Its Production and Uses. By E. F. Willoughby (Griffin.) 6s. net.
Milk, Cheese, and Butter: A Practical Handbook on their Properties and the Processes of their Production. By J. Oliver. (Lockwood.) 7s. 6d.

Forestry

Economics of Forestry. By B. E. Fernow. (Spon.) 7s. 6d.
Timbers, and How to Know Them. By R. Hartig. Translated by W. Somerville. (Douglas.) 2s.
Our Forests and Woodlands. By J. Nisbet. (Dent.) 3s. 6d.
Manual of Injurious Insects. By Miss E. A. Ormerod. (Simpkin, Marshall.) 5s.
Manual of Forestry. 5 vols. I., Forest Policy in the British Empire, 6s.; II., Sylviculture, 9s.; and III., Forest Management, by W. Schlich, 9s. IV., Forest Protection, 12s.; V., Forest Utilisation, by W. R. Fisher, 12s. (Bradbury, Agnew.)
Timber, and Some of Its Diseases. By H. M. Ward. (Macmillan.) 6s.
Practical Forestry. By C. E. Curtis. (Crosby, Lockwood.) 3s. 6d.
English Estate Forestry. By A. C. Forbes. (Arnold.) 12s. 6d.
Practice of Forestry. By P. T. Maw. (Fisher Unwin.) 17s.
Law of Forestry in Great Britain and Ireland. By B. W. Adkin. ("Estates Gazette.") 10s.
Forest Entomology. By A. T. Gillanders. (Blackwood.) 15s.
Principles of Handling Woodlands. By H. S. Graves. (Chapman & Hall.) 6s. 6d. net.
The New Forestry. By J. Simpson. (Pawson & Brailsford.) 15s. net.
British Forest Trees and their Sylvicultural Characteristics and Treatment. By J. Nisbet. (Macmillan.) 6s. net.
Complete Yield Table for British Woodlands. By P. T. Maw. (Crosby, Lockwood.) 7s. 6d. net.

CHEMISTRY

Embracing the Theory and Practice of Chemistry in its Manifold Applications

See also Physics and Electricity

The New Chemistry. By Josiah Parsons Cooke. 400 pages. Kegan Paul .. .. 5s. Originally delivered as Lowell Lectures in 1871, the contents of this book were revised in 1884, and at that date formed a succinct and interesting summary of chemistry in its latest phases.

Chemical Research in its Bearings on National Welfare. By Emil Fischer. S.P.C.K. .. 1s. 6d. An impassioned plea for pure scientific chemical research, by one of the greatest of living chemists. Fischer points out the value of the great German industries that have been built on modern chemistry, and shows how England suffered by taking a narrow view of chemistry.

The Principles of Chemistry. By D. Mendeléeff. Two vols. Illustrated. Longmans .. 32s. One of the great classics of science, by the Newton of modern chemistry, discoverer of the periodic law in the relation of the elements of the universe. It was in writing this book, which aims at presenting the generalisations rather than the facts of chemical research, that the famous Russian man of science made his great discovery. Begins with simple facts and ends in magnificent generalisation.

The Scientific Foundations of Analytical Chemistry. By William Ostwald. Macmillan .. 6s. net An elementary work on the art of breaking up compounds into their elements and determining their nature; deals with the newly discovered knowledge and laws that now permit the theory of analytical reactions to be formed. A standard work, by a master of modern science.

Chemistry. By Sir W. A. Tilden. 108 pages. Illustrated. Dent .. .. .. 1s. net Attempts to explain the fundamental principles of chemistry to a reader entirely ignorant of the subject. An excellent elementary introduction by a first-rate authority.

Chemistry in Space. By Van't Hoff. Clarendon Press .. .. 4s. 6d. The book in which Van't Hoff "solved, to a certain extent, and for carbon compounds only, the problem as to the position of the atoms in the molecule." Ten years earlier he had introduced his theory in a pamphlet in Dutch. It was now formally set forth and argued, and since has been made the basis of organic chemistry, and has secured the Nobel Prize for originality and usefulness.

The Chemical History of a Candle. By Michael Faraday. 113 pages. Illus. Hutchinson. 10d. net Famous popular lectures by the great chemist. With introduction by Sir W. Crookes.

Physical Chemistry: its Bearings on Biology and Medicine. By James C. Philip. Arnold. 7s. 6d. net A series of chemical lectures to students of biology. Gives an outline of the modern discoveries of chemical processes of living tissues. Colloids and solutions and similar phenomena are clearly and accurately explained.

The Chemistry of the Radio-Elements. By Frederick Soddy. Longmans .. .. 5s. 6d. net A summarised account of recent progress on the main lines of research in radio-activity. Gives a general description of radio-activity, and the periods of average life of radio-active substances, with a classification of the new kind of elements. It deals in detail with the latest researches on radium, uranium, thorium, and similar forms of matter.

Elementary Chemistry. By F. B. Emery. 629 pages. Illustrated. Williams & Norgate .. 8s. 6d. net An excellent introduction to the subject, of the school-book type. Deserves special mention as a laboratory manual, giving due place to metallurgy.

An Introduction to Chemistry and Physics. By W. H. Perkin and B. Lean. Macmillan .. 3s. 6d. Intended as a manual for students. Deals with birth of chemistry; measurements of mass, temperature, and volume; preparation of the common acids and alkalis, and formation of salts. In the second part are explained the study of fire and air; the rusting of iron; the discovery of the metals; the composition of water and properties of gases, and the transformation of matter.

Chemistry. By Raphael Meldola. 247 pages. Williams & Norgate .. .. 1s. net Deals in a popular way with the principles of chemical science and its manifold relations to other branches of knowledge. Comprehensive and modern.

The Chemistry of Fire. By M. M. P. Muir. 163 pages. Illustrated. Methuen .. .. 2s. 6d. Sets forth in a simple way the chief principles of chemistry, by the study of the burning of a candle.

Outlines of Physical Chemistry. By George Senter. 387 pages. Illustrated. Methuen .. .. 5s. An elementary introduction to the science, but the writer assumes that the student has some knowledge of chemistry and physics. Deals in considerable detail with the branches of the subject that usually present most difficulty to the beginner, such as the theory of solutions, the principles of chemical equilibrium, and electro-motive force. Electro-chemistry is fully treated. Suitable for electrical engineers.

Recent Advances in Physical and Inorganic Chemistry. By Alfred W. Stewart. Longmans. 7s. 6d. net Deals with researches that have been carried out in the last twenty years. The chief aim of the author was to avoid, as far as possible, themes that have been fully dealt with in textbooks, so as to attain a novelty in the subject-matter. Treats of experimental chemical geology, radio-activity, the rare earths, and the fixation of nitrogen.

The Gases of the Atmosphere: the History of their Discovery. By Sir William Ramsay. 308 pages. Illustrated. Macmillan .. .. .. 6s. net Having taken a leading part in the discovery of the rarer elements of the common air, the author relates the interesting and instructive discovery of exygen and nitrogen and the other gases in the atmosphere in which we live. A standard work.

Modern Organic Chemistry. By C. A. Keane. 503 pages. Illustrated. Walter Scott .. .. 6s. An attempt to lay down stepping-stones to the general principles and technicalities of organic chemistry, and to illustrate the methods and applications of the science by simple and typical examples.

Beyond the Atom. By J. Cox. Cambridge University Press .. .. 1s. net An attempt to tell in a short compass the romantic story of the modern discoveries which have led men to divide atoms into immeasurably smaller forms.

A Textbook of Inorganic Chemistry. By G. S. Newth. 724 pages. Illus. Longmans .. 6s. 6d. Contains a sketch of the fundamental principles and theories upon which the science of modern chemistry is built. This is followed by a study of the four typical elements—hydrogen, oxygen, nitrogen, and carbon—and their important compounds. In the last part of the book the elements

are treated in a systematic manner, according to the periodic law.

Natural Sources of Energy. By A. H. Gibson. Cambridge University Press .. .. 1s. net
The natural sources discussed include fossil fuels, solar heat, vegetation, the earth's internal heat, water power, tidal power, and wind power. The author concludes that from these and other sources the human race will be supplied with energy for all its conceivable activities during an enormous period.

The Chemistry of Commerce. By Robert Kennedy Duncan. Harpers .. .. .. 7s. 6d. net
A series of miscellaneous chapters of much interest, showing new applications of science. Among the subjects are the fixation of nitrogen, rare earths, high temperatures in relation to industry, industrial alcohol, microbe inoculation, and cellulose. The author writes interestingly for "educated lay folks," and the book is amply illustrated.

APPLIED CHEMISTRY

GENERAL TREATISES

Chemistry for Engineers and Manufacturers. By B. Blount and A. G. Bloxam. (Griffin.) Vol. I. 14s. Vol II., 16s
Manual of Chemical Technology By R. O. Wagner and Sir W. Crookes. (Churchill.) 32s.
Chemical Technology. By C. E. Groves and W. Thorp. (Churchill.)
Vol I., Fuel. By E. J. Mills and F. J. Rowna. 30s. Vol. II., Lighting. By W. Y. Dent and others. 20s. Vol. III., Gas Lighting. By C. Hunt. 18s.
A Dictionary of Applied Chemistry. By T. E. Thorpe. (Longmans.) 3 vols. Vols. I. and II., 41s. each. Vol. III., 63s.
Industrial and Manufacturing Chemistry. By G. Martin. (Lockwood.) 21s.

CHEMICAL ANALYSIS

Handbook of Technical Gas Analysis. By C. Winkler. (Gurney & Jackson.) 10s. 6d.
Lubrication and Lubricants. By L. Archbutt and R. M. Deeley. (Griffin.) 25s. net.
Laboratory Book of Mineral Oil Testing. By J. A. Hicks. (Griffin.) 2s. 6d. net.
Painters' Laboratory Guide. By G. H. Hurst. (Griffin.) 5s.
Select Methods in Chemical Analysis. By Sir W. Crookes. (Longmans.) 21s. net.
Methods of Gas Analysis. By W. Hempel. (Macmillan.) 10s. net.
Analytical Chemistry. By A. Menschutkin. (Macmillan.) 17s. net.
Quantitative Analysis. By F. Clowes and J. B. Coleman. (Churchill.) 10s.
Quantitative Analysis. By R. Fresenius. (Churchill.) Vol. I., 15s. Vol. II., parts 1—3, 2s. 6d. each.
Laboratory Teaching. By A. G. Bloxam. (Churchill.) 6s. 6d.
Volumetric Analysis. By F. Sutton. (Churchill). 18s. 6d.
Commercial Organic Analysis. By A. H. Allen. (Churchill.) 4 vols.
Vol. I., Alcohols, Starch, Sugars, etc., 18s.
Vol. II., Part 1, Oils, Fats, and Glycerin. 14s.
Vol. II., Part 2, Petroleum, Coal-tar Products. 14s.
Vol. II., Part 3. Phenols, Aromatic Acids, Resins and Essential Oils. 20s.
Vol. III., Part 1. Tannins, Dyes, Colouring Matters and Inks. 18s.

Vol. III., Part 2. Amines, Nitrogenous Bases, Antipyretics, and Alkaloids. 18s.
Vol. III., Part 3. Vegetable Alkaloids, Bitter Principles, Cyanogen Derivations. 16s.
Vol. IV., Proteins and Albuminous Substances. 18s.
Technical Methods of Chemical Analysis. By Lunge and Keane. (Gurney & Jackson.) 3 vols. Vol. I., £2 12s. 6d. Vol. II., £3 3s. Vol. III., £3 3s. net.

ACIDS AND ALKALIES

Sulphuric Acid and Alkali. By G. Lunge. (Gurney & Jackson.) Vol. I., £3 3s. Vol. II., £2 2s. Vol. III., £1 10s.
Coar-tar and Ammonia. By G. Lunge. (Gurney & Jackson.) £2 2s.
Alkali-Makers' Handbook. By Lunge and Hurter. (Whittaker.) 10s. 6d.
Ammonia and its Compounds. By Dr. J. Grossman. (Harper.) 2s. 6d. net.
Manufacture of Sulphate of Ammonia. By G. T. Calvert. (Allan.) 7s. 6d. net.

OILS, FATS, WAXES, RESINS, SOAP, CANDLES, AND GLYCERIN

Chemical Technology of Oils and Waxes. By Dr. J. Lewkowitsch. (Macmillan.) 3 vols. Vol. I., 25s. net. Vol. II., 25s. net. Vol. III., 20s. net
Laboratory Companion to Fats and Oils Industries. By Dr. J. Lewkowitsch. (Macmillan.) 6s. net.
Analysis of Oils, etc. By A. C. Wright. (Lockwood.) 9s. net.
Oils, Fats, and Waxes. By C. R. A. Wright and C. A. Mitchell. (Griffin.) 25s. net.
Soaps: A Practical Manual of Manufacture. By G. H. Hurst. (Scott, Greenwood). 12s. 6d. net.
Glycerine: Its Production, Uses, and Examination. By S. W. Koppe. (Scott, Greenwood.) 7s. 6d. net.
Lubricating Oils, Fats, and Greases. By G. H. Hurst. (Scott, Greenwood.) 10s. 6d. net.
Modern Soaps, Candles, and Glycerine. By L. L. Lamborn. (Lockwood.) 30s. net.
Art of Soap-making. By A. Watt. (Lockwood.) 7s. 6d.
Soap Manufacture. By W. L. Gadd. (Bell.) 5s.
Chemistry of the Oil Industries. By J. E. South combe. (Constable.) 7s. 6d. net.
Fatty Foods. By Bolton & Reuis. (Churchill) 10s. 6d.

PAINTS AND POLISHES

Manufacture of Lubricants, Shoe Polishes, and Leather Dressings. By R. Brunner. (Greenwood.) 7s. 6d. net.
Manufacture of Paint. By J. Cruikshank Smith. (Greenwood.) 10s. 6d. net.
Manufacture of Lake Pigments. By F. H. Jennison. (Greenwood.) 7s. 6d. net.
Painters' Colours, Oils, and Varnishes. By Hurst and Heaton. (Griffin.) 10s. 6d. net.
Industrial and Artistic Technology of Paint and Varnish. By A. H. Sabin. (Chapman & Hall.) 12s. 6d.
The Chemistry and Technology of Mixed Paints. By Max Toch. (Lockwood.) 12s. 6d. net.
Paint and Colour Mixing. By A. S. Jennings. (Spon.) 5s. net.
Manufacture of Varnishes. By Livache and MacIntosh. (Greenwood.) 3 vols. Vol. I., 7s. 6d. net. Vol. II., 10s. 6d. net. Vol. III., 12s. 6d. net.
A Treatise on Colour Manufacture. By Zerr, Ruben Camp, and Mayer. (Griffin.) 30s. net.

GLUES AND ADHESIVES

Glue and Glue Testing. By S. Rideal. (Greenwood.) 10s. 6d. net.

Sealing-Waxes, Wafers, and other Adhesives. By H. C. Standage. (Greenwood.) 5s. net.
Glue, Gelatine, and Allied Products. By T. Lambert. (Griffin.) 5s. net.
Cements, Pastes, Glues, and Gums. By H. C. Standage. (Lockwood.) 2s. 6d. net.
Agglutinants of All Kinds for All Purposes. By H. C. Standage. (Constable.) 6s. net.

INKS

Ink Manufacture. By S. Lehner. (Greenwood.) 5s.
The Manufacture of Ink. By C. A. Mitchell and T. C. Hepworth. (Griffin.) 7s. 6d. net.
Oil Colours and Printers' Inks. By L. E. Andes. (Greenwood.) 5s. net.

TAR AND WOOD DISTILLATION

Chemistry of Coal-tar Colouring. By Benedikt. (Bell.) 6s. 6d.
Synthetic Dyestuffs. By J. C. Cain and J. F. Thorpe. (Griffin.) 16s. net.

FERTILISERS AND MANURES

A Treatise on Manures. By A. B. Griffiths. (Whittaker.) 6s. net.
Manufacture of Chemical Manures. By J. Fritsch. Scott, Greenwood). 10s. 6d.
Fertilisers. By E. B. Vorhees. (Macmillan.) 5s. 6d.
Bone Products and Manures. By T. Lambert. (Greenwood.) 7s. 6d. net.
Fertilisers and Manures. By A. D. Hall. (Murray.) 5s. net.
Artificial Manures. By M. Georges Ville. (Longmans.) 10s. 6d. net.
See also under "Acids and Alkalies" and "Agriculture."

CELLULOSE AND PAPER-MAKING

Cellulose. By C. F. Cross, E. J. Bevan, and C. Beadle. (Longmans.) 12s.
Researches on Cellulose. Parts I. and II. By C. F. Cross and E. J. Bevan. (Longmans.) 6s. each.
Practical Paper-making. By George Clapperton. (Lockwood.) 5s.
Paper and Its Uses. By E. A. Dawe. (Lockwood.) 4s. 6d. net.
Estimation of Moisture in Pulp. By Otto Winkler. (Clayton Beadle & Stevens.) 2s.
C.B.S. Units, or Standard Paper Tests. By C. F. Cross, E. J. Bevan, Clayton Beadle, and R. W. Sindall. (Spon.) 2s. 6d.
Six Lectures on Paper Manufacture. By Clayton Beadle. (Croxley Institute.) 3s.
Sampling of Wood Pulp. By R. W. Sindall. (Becker.) 2s.
Leunig's Tables of Sizes of Papers. By F. Leunig. (Mardon & Hall.) 1s.
Chapters on Paper-making. By Clayton Beadle. (Lockwood.) Vols. I. to V., 5s. net each vol.
Fibrous Constituents of Paper. By Clayton Beadle. (Newnes.) 15s.
Paper Technology. By R. W. Sindall. (Griffin.) 12s. 6d.
The Paper Trade. By A. Dykes Spicer. (Methuen.) 12s. 6d.
The Paper-mill Chemist. By H. P. Stevens. (Greenwood.) 7s. 6d.
Wood Pulp and Its Uses. By C. F. Cross. (Constable.) 6s. net.

GENERAL

Elements of Electro-Chemistry. By M. Le Blanc. (Macmillan.) 6s.
Electro-Chemistry. By R. A. Lehfeldt. (Longmans.) 2 vols. 5s. each.
Microscopy of the Starches. By H. Galt. (Ballière, Tindall & Cox.) 3s. 6d. net. See also General Treatises under "Applied Chemistry."
Utilisation of Wood Waste. By E. Hubbard (Greenwood.) 5s. net. See also General Treatises.
Celluloid; Its Raw Material, Manufacture, Properties, and Uses. By Dr. Fr. Böckmann. (Scott, Greenwood.) 5s. net.
Celluloid. Translated from French of Masselin, Roberts, and Cillard by Hodgson. (Griffin) 25s. net
Water Softening and Purification. By Harold Collet. (Spon.) 5s. net.
Water Supplies: their Purification, Filtration, and Sterilisation. By S. and E. Rideal. (Lockwood.) 7s. 6d. net.

WASTE PRODUCTS

Utilisation of Waste Products. By T. Koller. (Greenwood.) 7s. 6d. net. See also under "Wood Distillation."
Coal-tar Distillation. By D. R. Warnes. (Allan.) 7s. 6d. net. See also under "Acids and Alkalies" and General Treatises.

DYEING

A Manual of Dyeing. By Knecht, Rawson, and Löwenthal. (Griffin.) 2 vols. 45s. net.
A Practical Manual of Wool Dyeing. By C. Bolton. (Heywood.) 12s. 6d. net.
The Dyeing of Cotton Fabrics. By Franklin Beech. (Scott, Greenwood.) 7s. 6d. net.
The Dyeing of Woollen Fabrics. By Franklin Beech. (Scott, Greenwood.) 7s. 6d. net.
Principles of Dyeing. By G. S. Fraps. (Macmillan.) 7s. net.
Dictionary of Dyes, Mordants, and other Compounds used in Dyeing and Calico Printing. By Rawson, Gardner, and Laycock. (Griffin.) 16s. net.
The Chemistry of Dyestuffs. By Georg von Georgievics. (Scott, Greenwood.) 10s. 6d. net.
Systematic Survey of the Organic Colouring Matters. By A. G. Green. (Macmillan.) 21s.
Dyers' Materials. By Paul Heerman. (Scott, Greenwood.) 5s. net.
Aniline Black, and its Application in Dyeing and Printing. By E. Noelting and A. Lehne. (Heywood.) 12s. 6d. net.
Silk Dyeing, Printing, and Finishing. By G. H. Hurst. (Scott, Greenwood.) 7s. 6d. net.
Colour Matching on Textiles. By David Paterson. (Scott, Greenwood.) 7s. 6d. net.
Textile Colour Mixing. By David Paterson. (Scott, Greenwood.) 7s. 6d. net.
Dyeing and Cleaning. By Frank J. Farrell. (Griffin.) 5s. net.
Treatment of Effluent from Dyehouses. By J. H. Garner. (Society of Dyers and Colourists.) 2s. 6d.
The Art of Dyeing and Staining Marble, Artificial Stone, Bone, Horn, Ivory, and Wood, and of Imitating all sorts of Wood. By D. H. Soxhlet. (Scott, Greenwood.) 5s. net.
Textile Fibres: Their Physical, Microscopical and Chemical Properties. By J. M. Matthews. (Chapman & Hall.) 17s. net.
The Chemical Technology of Textile Fibres: Their Origin, Structure, Preparation, Washing, Bleaching, Dyeing, Printing, and Dressing. By Dr. Georg von Georgievics. (Scott, Greenwood.) 10s. 6d. net.
Colour in Woven Design. By Roberts Beaumont. (Whittaker.) 18s. net.
Colour. By G. H. Hurst. (Scott, Greenwood). 7s. 6d. net.

HISTORY

Embracing the Ancient and the Modern World

General History

A History of Modern Liberty. By James Mackinnon. Longmans. 3 vols. .. 15s. each
This important work, planned in eight volumes, has been brought down to the year 1647 in the first three vols. Professor Mackinnon combines in his writing dignity with lucidity, while expressing his profound sense of the vital importance of the spirit of liberty.

The Fifteen Decisive Battles of the World. By Sir Edward Creasy. Macmillan. .. 2s. 6d.
Though the selection of decisive battles by the author would not now satisfy any student of history, the book gives a useful series of historical pictures that have an attractive panoramic effect, and it is written with such fine verve that it has given many young readers a taste for history.

Critical and Historical Essays. By Lord Macaulay. Longmans. .. .. .. 6s. and 2s. 6d.
No writer has approached Macaulay as a populariser of history. The very defects of his style—its bold and persistent contrasts, for example, and its eagerly partisan portraiture—wake up the most sluggish from indifference. He was a "bonnie fighter" with the pen, and even as a dogmatist is a historian to be reckoned with. The Essays are a classic that will hold their place.

Introduction to Historical Studies. By C. V. Langlois and C. Seignobos. Duckworth. 5s. net.
A preliminary work, translated from the French, on the true methods of historical study. Appeals to the genuine student.

Flags of the World. By W. J. Gordon. Warne. 6s.
The only popular book on the flags of all nations that appears to give what is wanted. A most comprehensive collection, with hundreds of pictures, embracing every kind of flag, and the story of their associations.

Lectures on Modern History. By Lord Acton. 381 pp. Macmillan .. .. .. 10s. net
Lord Acton is the historian who may be said to have founded the modern English historical school, with impartiality as its ideal. The prefix contains his lecture on the Study of History, and in an Appendix his letter of instructions to the contributors to the "Cambridge Modern History" is given. This book reveals the true spirit of historical inquiry. The lecture on the Study of History is also published separately, with copious notes, at half a-crown.

The Influence of Sea-Power upon History. By A. T. Mahan. Low .. .. .. 21s. net
One of the master-books of modern literature, calling the attention of the whole world to great tendencies that formerly only appealed to military and naval experts. Mahan takes quite a distinctive position in American literature.

History of Civilisation. By Henry T. Buckle. Various editions. Cheapest by Routledge. 5s. net
A most interesting theory of historical development. To be used for its thought-provoking suggestions rather than for uncritical acceptance.

A General Sketch of Political History from the Earliest Times. By A. D. Innes. Rivingtons. 3s. 6d.
A very useful survey, on the broadest lines, of historical developments in all times and countries.

A general scheme of history, showing how racial and national movements influence each other.

Gesta Christi. By C. Loring Bruce. Hodder & Stoughton .. ..6s. net
A valuable record of the influence of Christianity on the development of the world, treating each field of activity separately.

Myths and Legends of the Middle Ages. By H. A. Guerber. Illustrated. Harrap .. 7s. 6d. net
The Middle Ages were times when fancy was unrestrained, and naturally expressed itself in poetical conceptions and stories. Here a great array of these stories is marshalled from the literatures of all nations. The narratives are retold with vigour and the illustrations are admirably apt.

Ancient World

The Dawn of History. By J. L. Myres. 256 pp. Williams & Norgate. .. .. .. 1s. net
One of the most striking volumes of the Home University Library. A remarkable compendium of knowledge, quite up to date.

The Dawn of Civilisation and Chaldæa. By Sir Gaston C. Maspero. S.P.C.K. .. 21s. net
The first part of Maspero's "History of the Ancient Peoples of the Classic East." It includes the early history of Egypt and Chaldea. The author has a knowledge of the East that is unsurpassed.

The Struggle of the Nations. By Sir Gaston C. Maspero. S.P.C.K. .. .. .. 21s. net.
The second part of the author's colossal "History of the Ancient Peoples of the Classic East." It covers the later period of Egyptian history, under Theban dynasties, and the rise of Assyrian power.

The Passing of the Empires. By Sir Gaston C. Maspero. S.P.C.K. .. .. .. 21s. net
The last section of Maspero's History of the Ancient East. It follows the rise and fall of the Mesopotamian and Persian Powers from the overthrow of Babylon to the conquests of Alexander, and, though much more information has been gathered since the book was written, it remains the standard work for the period pictured.

The Ancient History of the Near East. By H. R. Hall. Methuen .. .. .. 15s. net
An admirable summary of the knowledge deposited in such works as Maspero's on the early history of the East, with the addition of more recent knowledge gained from excavatory research.

A History of Sumer and Akkad. By L. W. King. Chatto & Windus .. .. .. 18s. net
The first part of a comprehensive history of ancient Babylonia, written by one of the world's leading experts in Mesopotamian history and literature. It reveals a language and civilisation that had become overlaid by the dust of Time.

History of Babylonia and Assyria. By R. W. Rogers. 2 vols. Luzac .. .. £1 net
A convenient summary of the history of Babylonia and Assyria, brought well up to date, and superseding histories written before modern research had decided many problems of the buried Empires.

The Land of the Hittites. By J. Garstang. Constable. .. .. 12s. 6d. net
A book which gathers together what is known and what is surmised about the Hittites of Central Asia Minor, a people whose place in the world is gradually being fixed by research and the controversies that follow research.

The Ancient East. By D. G. Hogarth. 256 pp. Williams & Norgate. .. .. .. 1s. net
A series of pictures of the East, at intervals of two hundred years, beginning with 1000 B.C., by the Keeper of the Ashmolean Museum, Oxford. Great additions have been made in recent years to our knowledge of the East, and new perspectives are not only possible but necessary. Mr. Hogarth is in touch with all this new learning from archæological sources, and is very happy in his expositions.

A History of Egypt from the Earliest Times to the Persian Conquest. By James H. Breasted. 663 pp. Hodder & Stoughton .. .. .. 20s. net
An up-to-date history of Egypt, written in an interesting style by the Professor of Egyptology of Chicago University. Admirably illustrated.

Egypt and Western Asia in the Light of Recent Discoveries. By L. W. King and H. R. Hall. S.P.C.K. .. .. 10s. net
A volume written by historians and excavators of great experience, and serving to bring up to date the kind of information given to the world in the great Eastern history by Maspero. Necessary for the student of newly won knowledge.

History of Egypt from the Earliest Times. By W. M. Flinders Petrie. 6 vols. Methuen. 6s. each
The standard history of the Nile Valley as it can now be mapped out through the discoveries of excavators and a comparison of the story told by their disinterred relics with written records.

History of Greece. By George Grote. 12 vols. Dent. .. .. 1s. net. each vol.
One of the world's most ambitious books, Grote's "Greece" had the trying fate of dealing freely, in its earlier portions, with questions on which information was scanty at the time of writing, and now is comparatively abundant. Grote had to make inferences on points that are now settled by knowledge, owing to the evidence disinterred by archæology. The result is that the earlier part of his work is superseded to a considerable extent. The latter part is still of permanent value.

Greek Life and Thought. By J. P. Mahaffy. 771 pages. Macmillan .. .. .. 12s. 6d.
A semi-popular exposition of the influence of Greece on the world, after Alexander's conquests until the supersession of Greek thought by Roman power.

A History of Greece to the Death of Alexander the Great. By J. B. Bury. 932 pages. Illustrated. Macmillan. .. .. 8s. 6d.
A final manual of Greek history by the Regius Professor of Modern History at Cambridge. Equally learned and attractive.

The Oldest Code of Laws in the World. By C. H. W. Johns. 88 pages. T. & T. Clark .. 1s. 6d. net
A complete text of the legal code of Hammurbia, King of Babylon, about 2000 B.C. The discovery of this code was hailed as the greatest event in Biblical archæology for many years. Dr. Johns is one of the highest living authorities in this branch of knowledge.

Outlines of Roman History. By H. F. Pelham. 554 pages. Rivingtons. .. .. 6s.
A singularly clear and well-arranged handbook, which a rival writer has described as masterly.

PRICES OF BOOKS

In all cases the prices in this list are the maximum prices, and in many cases, whether indicated or not, there may be a discount of threepence in the shilling. Almost invariably shilling books, and nearly all technical works, are net.

A History of the Ancient World. By Hutton Webster. Harrap .. .. .. 6s. net
An admirable general sketch of the history of the world to the fall of Rome, with an abundance of illustrations and maps that force the reading matter on the attention of the student.

Plutarch's Lives. Dryden's translation. 3 vols. Dent .. .. 3s. net
The most popular historical work that has reached us from antiquity.

A History of the Roman Empire. By John B. Bury. 646 pages. Illustrated. Murray. .. 7s. 6d.
This handbook, by the first living authority, ends with the death of Marcus Aurelius. A definitive survey, sound and attractive.

Social Life at Rome in the Age of Cicero. By W. Warde Fowler. Macmillan .. 10s. net
The author of this book has a very graphic pen. He tells, with Cicero's correspondence as his guide, how people lived in Rome in the great days of old. A picturesque book, written with insight and sympathy.

The City-State of the Greeks and Romans. By W. Warde Fowler. 350 pages. Macmillan .. 5s.
A sketch of the localised organisation of the Greek and Roman peoples before the days of the Empire. Scholarly and vigorous.

The History of Rome. By Theodor Mommsen. Five vols. Macmillan. .. .. .. 37s. 6d.
An unrivalled work, with Cæsar as its hero. Shows "a true insight into the relative importance of things," and "paints with astonishing vigour the great political struggle that accompanied the fall of the republic." This edition includes two of Mommsen's books.

The Decline and Fall of the Roman Empire. By Edward Gibbon. Edited by Dr. Bury. Illustrated. 7 vols. Methuen. .. .. .. 73s. 6d. net
Cheap editions by various publishers.
A stupendous history, written with fine dignity. The life-work of a clever man with few positive opinions, and those reflecting the eighteenth century tone of polite thought. In style it "passes with a proud precision, like a Roman legion through a troubled country." One of the world's most memorable books.

Ionia and the East. By D. G. Hogarth. Clarendon, Press .. .. 4s. 6d. net
A discussion of the new evidence respecting the beginnings of historic Greece, written by the learned Keeper of the Ashmolean Museum at Oxford. Necessary for the student of newly won knowledge.

Crete the Forerunner of Greece. By Mr. and Mrs. Hawes. Harper. .. .. .. 2s. 6d. net
A summary of the knowledge gained in quite recent years respecting the Minoan Age in Crete. The writers have personal knowledge of the methods and results of research.

Epochs of Ancient History. Edited by Sir G. W. Cox and C. Sankey. 10 vols. Longmans. 2s. 6d. each.
Besides the editors, the writers of volumes in this useful series of school histories, relating to Greece and Rome, include Dr. Charles Merivale and R. Bosworth Smith. The closing date is A.D. 180.

European History

A General Sketch of European History. By Edward A. Freeman. 375 pages. Macmillan .. 3s. 6d.
A popular book for secondary schools, bringing

along abreast, in broad outline, the stories of the different European lands, and showing their relation to each other, and the interaction of influences.

European History. An Outline of its Development. By George B. Adams. 605 pages. Illustrated. Macmillan .. .. 6s. net
A valuable textbook by the Professor of History in Yale University. Extensive bibliography.

Periods of European History. Rivington 8 vols. 6s.
An excellent series, ranging from A.D. 476 to the end of the nineteenth century. Written by Oxford men, among whom are Professor Oman, Tout, Lodge, Morse Stephens, W. Alison Phillips, and Arthur Hassall, tutor of Christ Church. These volumes are authoritative students' handbooks.

Medieval Europe. By H. W. C. Davis. 256 pages. Williams & Norgate .. .. .. 1s. net
An admirable historical summary from the fall of the Western Roman Empire to about 1250. The author keeps in mind social and commercial as well as racial and political developments.

The Holy Roman Empire. By Viscount Bryce. 506 pages. Macmillan .. .. .. 7s. 6d.
The best work on the period and area covered—from 962 to 1806, in East-Central Europe. A brilliant book, that stands alone. It deals with events and characters of which the average British reader knows but little.

The Medieval Empire. By Herbert A. L. Fisher. 673 pages. 2 vols. Macmillan .. 21s. net
A book which covers much the same ground as Bryce's "Holy Roman Empire." Dr. Fisher, who is Vice-Chancellor of Sheffield University, writes with fine compression yet vigorous movement.

History of Europe during the Middle Ages. By Henry Hallam. Murray .. .. .. 7s. 6d.
Hallam's "View of the State of Europe during the Middle Ages" is described by Leslie Stephen as "probably the first English History which, without being merely antiquarian, set an example of genuine study from original sources."

Cambridge Modern History. Edited by Sir A. W. Ward, Dr. G. W. Prothero, and Stanley Leathes. 12 vols. Cambridge Univ. Press 150s. the set; 16s. per vol.
This great work, planned by Lord Acton, begins with the Renaissance and reaches the present day. It is written by a large and carefully chosen staff of contributors, and incorporates the results of the most recent historical researches. There are two additional volumes, of tables, maps, and index, costing 41s. (to subscribers 25s.). It is being followed by the Cambridge Mediæval History, in eight volumes, price £6 net, planned by J. B. Bury, and now in preparation. Two volumes are ready. The splendid historical work issuing from Cambridge is largely due to the influence of the late Lord Acton.

Epochs of Church History. Edited by Mandell Creighton. 12 vols. Longmans .. 2s. 6d. each
A well-written series of manuals on the story of the Church in its wider meaning. The most memorable periods, in England and abroad, are covered, the writers including some well-known experts, such as Dr. A. W. Ward (on the Counter-Reformation), Reginald L. Poole (the Wycliffe Period), the Rev. W. Hunt, and the Rev. W. R. W. Stephens. The outlook is broad enough to embrace the Greek Church as well as the Roman and English Churches, the Evanglical Movement, and University History.

A History of the Papacy. By Mandell Creighton. 6 vols. Longmans .. .. .. 5s. each net
The period covered by this important work is from 1378 to 1527. The book is the most considerable production of a historian who was conspicuous for his impartiality and his industrious mastery of the facts bearing on his subject.

The Papacy and Modern Times. By Wm. Barry. 256 pages. Williams & Norgate .. 1s. net
This book is a sketch of the political phase of the Church of Rome; that is, the relation of the Church to Temporal Power and Suzerainty over Kings. The author calls it "a chapter in the history of spiritual freedom." Apparently he holds that the Church should rule by faith and not by force.

A History of Modern Europe. By C. A. Fyffe. 1088 pages. Maps. Cassell .. .. 10s. 6d.
A book in very wide use in newspaper offices. It gives a lucid sketch of European changes between the French Revolution and about 1880. There is no book on quite the same lines, and it ought to be brought up to date.

The Development of the European Nations. By J. Holland Rose. Maps. Constable .. 7s. 6d. net
The period covered by this book is 1870 to 1900. Dr. Rose is a clear, succinct writer, with well-balanced judgment, and cleverly carries on the story of Europe from the point where histories usually end to the beginning of modern changes.

Governments and Parties in Continental Europe. By A. Lawrence Lowell. 2 vols. Longmans 21s.
An exceedingly interesting summary of European developments of government, by the President of Harvard University. It shows Europe as seen from without by a specially capable observer.

Epochs of Modern History. Edited by E. E. Morris, J. S. Phillpotts, and C. Colbeck. 19 vols. Longmans .. .. 2s. 6d. each
A useful set of textbooks, which includes Continental events and movements in so far as they are linked with English history. The writers include Dean Church, Dr. Creighton, Sir Geo. Cox, Dr. Stubbs, James Gairdner, Frederic Seebohm, Dr. S. R. Gardiner and Mrs. Gardiner, Justin McCarthy, and Mr. F. W. Longman.

Europe—Countries

The French Revolution. By Thomas Carlyle. Edited by J. Holland Rose. 3 vols. Illustrated. Bell. 21s. net. Many cheap editions.
A picturesque and emotional story that needs the accompaniment of a record of facts.

The French Revolution. By Hilaire Belloc. 256 pages. Maps. Williams & Norgate .. 1s. net
A clever unravelling of the tangled skein of the French Revolution, showing how and why its varying phases followed.

The Rise of the Dutch Republic. By John L. Motley. 942 pages. Routledge .. .. 3s. 6d.
A classical work, dealing with a turning-point in European history, and written with great charm by an enthusiastic student of Dutch life.

Turkey and Its People. By Sir Edwin Pears. Methuen .. .. 12s. 6d. net
No other Englishman knows Turkey as well as Sir Edwin Pears knows it, and he has the power of telling clearly what he knows. This work is a discussion of the country up to date; that is, it includes the pretended modernisation of the Government of the country under the disastrous influence of the "Young Turks." The complicated religious position of the country is fully explained. A book of unique value.

The United Netherlands. By John L. Motley. 2674 pages. 4 vols. Murray .. .. 6s. each vol.
A continuation of Motley's "Rise of the Dutch Republic." Displays wide learning and great labour, but lacks the movement of the earlier work.

France. By John E. C. Bodley. 703 pages. Macmillan .. .. .. 10s. net
A book of high value on the political position and methods of government in France, treated as an ultimate outcome of the Revolution. Quite a distinctive work.

The Civilisation of the Renaissance of Italy. By Jacob Burckhardt. 573 pages. Allen .. 10s. 6d.
A sound book on the effects on the individual, society, and the State, of the Renaissance.

The History of Florence. By Niccolo Machiavelli. 443 pages. Routledge.. .. .. 2s.
A memorable story of Florentine development and life, by one of the acutest of Italian intellects. Florence as seen from within during one of the most interesting periods of her history.

History of the Italian Republics in the Middle Ages. By J. C. L. Sismondi. Routledge .. 5s. net
A work of great interest to all who visit Italy and seek to penetrate to the sources of its artistic power.

History of the Reign of Ferdinand and Isabella. By W. H. Prescott. Routledge .. .. 3s. 6d.
A vigorous example of historical writing that paints broad effects yet depends on careful study of details. Though much new material is now available, the book remains of permanent value.

History of the Reign of Philip the Second. By W. H. Prescott. Routledge .. .. 3s. 6d.
The last work of the picturesque American historian, written when his sight had failed, but showing no loss of power to mirror the past through the mind's eye. A picture of Spain moving towards decline.

Serbia : Her People, History, and Aspirations. By Woislav M. Petrovitch. Harrap .. 3s. 6d. net
An authoritative and popular history of the Serbian people up to the Great War, with chapters on national beliefs and customs. The author is Attaché to the Serbian Legation in London.

Spain : Its Greatness and Decay, 1479–1788. By Major Martin A. S. Hume. Cambridge University Press .. .. 6s. net
A brilliant sketch of Spanish history, by a writer who has a fine grasp of the principles that underlie national greatness, and a fascinating style. Spain is the victim of an unsound political economy. The story told here is sad, but highly salutary

Stories from Dutch History. By Arthur H. Dawson. Harrap .. .. 3s. 6d. net
A simple narration of some of the outstanding features of Dutch history, which have an abiding interest for all liberty-loving people. The author chiefly follows Motley.

The Story of the Crusades. By E. M. Wilmot-Buxton. Harrap .. .. .. 3s. 6d. net
A swiftly sketched account of the Crusades, beginning with the career of Mahomet and extending to the fall of Constantinople. Sixteen illustrations. The writer shows energy and breadth.

Napoleon. By Herbert A. L. Fisher. 256 pages. Williams & Norgate .. .. .. 1s. net
A brilliantly successful sketch within a small compass of the most striking career of modern times. This book attains the ideal of what a popular history should be. It is the outcome of wide knowledge, a temperate judgment, and rare insight, and is written with compelling charm.

The Union of Italy, 1815–1900. By W. J. Stillman. Cambridge University Press .. .. 4s. 6d. net
The writer of this book knew Italy well, and loved her warmly, but he wrote his book at a time when she seemed laggard in fulfilment of her national destiny, and so the book strikes a pessimistic note. If this qualification is borne in mind, the summary of Italian history is valuable, but already Italy is dispelling rapidly the author's fears.

British Isles

Introduction to the Study of English History. By S. R. Gardiner and J. B. Mullingar. 487 pages. Kegan Paul .. .. 7s. 6d. net
A highly useful book for students from a bibliographical point of view. The developments of English history are traced in periods, and the books are mentioned that must be studied for a full knowledge of each epoch or important event. A footpath guide for the historical wayfarer.

The Student's History of England. By S. R. Gardiner. Numerous illustrations. Longmans .. 12s.
A most careful and impartial historical compendium —the best of its kind. The illustrations are admirably chosen, and cover not only portraiture and architecture, but the everyday activities of the people of each period.

The History of England. By A. F. Pollard. 256 pages. Williams & Norgate .. .. 1s. net
The best brief sketch of our country's history that has ever been written. Of more value than many cartloads of ponderous tomes.

History of England. By David Hume. Revised by J. S. Brewer. 2 vols. Murray .. .. 7s. 6d.
The interest of Hume's History comes largely from its place in the story of modern historical writing. It was the first broad survey of the country's condition, and the first that escaped from the evil of ponderosity. But its intense partisanship has left it a permanent warning, and not at all a guide.

A History of England. By Dr. J. Franck Bright. 5 vols. Longmans.
Mediæval Monarchy, 4s. 6d. ; Personal Monarchy, 5s. ; Constitutional Monarchy, 7s. 6d. ; Growth of Democracy, 6s. ; Imperial Reaction, 4s. 6d.
A general history from the coming of the English to the end of the nineteenth century. Careful and trustworthy, rather than brilliant. The writer was Master of University College, Oxford.

A Short History of the English People. By John Richard Green. 886 pages. Maps. Macmillan 8s. 6d.
The most popular modern history of England in a single volume, and deservedly so. It pictures the changing life of the people, instead of confining itself to drum and sceptre scenes. Delightfully written. Largely based on original research.

History of the English People. By John Richard Green. 8 vols. Macmillan .. 4s. net each vol.
An expansion of Green's popular Short History, and sustaining all the qualities which have made that book a standard work.

The Making of England. By John Richard Green. 475 pages. 2 vols. Maps. Macmillan.. 8s. net
Describes the coming of the English, and their organisation of the country according to Teutonic ideals. Vivid, flowing, picturesque.

The Expansion of England. By Sir J. R. Seeley. 367 pages. Macmillan .. .. .. 4s. net
The book which first caused the British people to realise the significance of its Colonial Empire and Imperial standing in the world. Original and brilliant.

A History of the British Nation. By Arthur D. Innes. Illustrations and maps. Jack.. 3s. 6d. net
A well-written narration of the country's story, on popular lines, amply illustrated.

Epochs of English History. Edited by Dr. Mandell Creighton. 8 parts in 1 vol. Longmans .. 5s.
A very sound school history, written by well-known historical students under the editorship of the late Bishop of London. It can be obtained in parts, or periods, divided at the dates 1066, 1216, 1485, 1603, 1688, 1784, and 1820, and finishing at 1897.

Historical Introductions to the "Rolls Series." By William Stubbs. Longmans .. .. 12s. 6d. net
The Rolls Series are the most valuable of all English publications of historical documents. Dr. William Stubbs, sometime Bishop of Oxford, the contributor of these Introductions, was not a lively writer, but was a dragon for facts—the bed-rock of history.

The English Constitution. By Walter Bagehot. 382 pages. Nelson .. .. .. 1s. net
A book marked by fine balance and insight, and written with incisive power. It shows the flowering of English history into Constitutional forms.

The Constitutional History of England. By F. W. Maitland. Cambridge University Press .. 12s. 6d.
This book is described by Sir Courtenay Ilbert, in his work on Parliament, as "the most brilliant and suggestive account that has yet been written of the development of English Constitutional history."

Constitutional History of England. By Dr. William Stubbs. 3 vols. Clarendon Press .. .. 36s.
A work that remains unsuperseded, according to Professor Tout. Stubbs "moves easily under a mass of learning, with accuracy, precision, and insight." The book closes with the year 1485. The author was enormously conscientious and laborious, but subject to powerful prepossessions, and much under the influence of German scholarship.

Constitutional History of England since the Accession of George III. By the Right Hon. Sir Thomas Erskine May. 3 vols. Longmans .. 27s. 6d. net
Originally in two volumes, and treating of the period 1760 to 1860, a third volume by Mr. Francis Holland has brought the work down to 1910. Sir Thomas Erskine May was Clerk to the House of Commons, and, as a great authority on Parliamentary procedure, turned naturally to the discussion of Constitutional History.

The Political History of England. Edited by Dr. W. Hunt and Reginald Lane Poole. 12 vols. Longmans .. .. .. 7s. 6d. net per vol.
A work of high value, written by extremely able specialists. One of the best historical series in the language. The writers and periods are: To 1066, Dr. Thomas Hodgkin; to 1216, George Burton Adam (Yale); to 1377, T. F. Tout (Manchester); to 1485, C. Oman (Oxford); to 1547, H. A. L. Fisher (Sheffield); to 1603, A. F. Pollard (London); to 1660, F. C. Montague (University College, London); to 1702, Richard Lodge (Edinburgh); to 1760, J. S. Leadam; to 1801, William Hunt; to 1837, G. C. Brodrick and J. K. Fotheringham; to 1901, Sidney Low and Lloyd C. Sanders. Most of these writers are, or have been, Professors of History, and they represent the highest modern type of historical inquirer.

History of the English Church. Edited by Stephens and Hunt. 9 vols. Macmillan .. 7s. 6d. each vol.
The best general History of the Church of England. It is based on a study of original authorities, and is written by authors of admitted standing in the world of historical research.

Constitutional History of England. By Henry Hallam. John Murray .. .. 7s. 6d.
A work of lasting merit, studiously impartial. It covers the period that includes on the one hand the reign of Henry VII., and on the other hand George II.

A Short History of the Catholic Church in England. By F. A. Gasquet. Catholic Truth Society .. 3d.
A reading of our country's history by the most able modern Catholic historian.

The Church of England. By Canon E. W. Watson. 256 pages. Williams & Norgate .. .. 1s. net
A rapid sketch of the Church of England as it has undergone permutations and developments along the centuries.

History of Religion in England. By Dr. J. Stoughton. 8 vols. Hodder & Stoughton £3
Deals with the subject with ability and moderation from the Nonconformist point of view.

The Sailors Whom Nelson Led. By Edward Fraser. Methuen .. .. 5s. net
A description of how Nelson's sailors won their battles, using the words of the officers and men who fought, or were eye-witnesses of what took place.

The Northmen in Britain. By Eleanor Hull. Harrap .. .. 3s. 6d. net
The story of the invasion of England by the Northmen is here told for the most part as it may be read or imagined by the light thrown on the sea-rovers from the Norwegian and Icelandic sagas.

History of England. Edited by C. Oman. 7 vols. Methuen .. .. .. 10s. 6d. net each
The writers of this important historical series are: Before the Normans—Charles Oman; Under the Normans—H. W. C. Davis; In the Later Middle Ages—Kenneth H. Vickers; Under the Tudors—A. D. Innes; Under the Stuarts—G. M. Trevelyan; Under the Hanoverians—C. G. Robertson; Since Waterloo—J. A. R. Marriott. The whole work is an Oxford product.

Wesley and His Century. By Dr. W. H. Fitchett. Smith, Elder .. .. 6s. net
Dr. Fitchett has the knack of picturesque writing. He can rivet attention by his first sentence. He does so in this brilliant study of Wesley in the midst of the eighteenth century. The book is a worthy monument of one of the most influential men of the modern world—"the little, long-nosed, long-chinned peremptory man who died in 1791, and left behind him nothing but a good library of books and the Methodist Church."

The Roman Era in Britain. By John Ward. Methuen .. .. 7s. 6d. net
A very able survey of the period named, as it may be studied from its "remains." The subjects specially discussed are roads, military remains, houses, public buildings and baths, religious buildings, sepulchral remains, pottery, utensils and implements, dress, toilet, and coins. The many illustrations, diagrams, and maps are well chosen and most helpful.

Sea Life in Nelson's Time. By John Masefield. Methuen .. .. 3s. 6d. net
A close and detailed study of life aboard ship in Nelson's day, as it presents itself to a lover of the sea who is also a man of genius.

A Short History of the Norman Conquest. By E. A. Freeman. Clarendon Press .. .. 2s. 6d.
A study by a historian who was a lover of research and accuracy, and who could write with vivid power, but who sometimes gave his work an appearance of baldness by his close adherence to Saxon English.

Anglo-Saxon Freedom. By James K. Hosmer. Walter Scott .. .. 7s. 6d.
The full title is descriptive of the scope of this book: "A short history of Anglo-Saxon freedom, the polity of the English-speaking race, outlined in its inception, development, diffusion, and present condition." The writer, a professor in Washington University, makes a strong point—indeed, his main point—of the solidarity of the great English-speaking nations, in stock, and in the spirit of their social and political institutions. An able survey.

The Domesday Inquest. By Adolphus Ballard. Methuen .. .. 7s. 6d. net
The Domesday Book was compiled to answer certain definite questions which must be borne in mind to understand it aright. These questions are made the foundation of this book, each being taken as the subject of a different chapter. The author knows thoroughly the best literature on his subject and has written a book of high value.

London Before the Conquest. By W. R. Lethaby. Macmillan .. .. 7s. 6d. net
There is no complete picture of London topography in the earliest times, and the popular views, the author of this book holds, are confused and misleading. He has therefore taken steps, in a series of notes, to clear the ground of manifest error and to prepare the way for an understanding of London as it really was. He has done useful work by way of clearance rather than of construction.

The Conquest of England. By John Richard Green. 2 vols. Maps. Macmillan .. .. 8s. net
The last work of the author. It traces the national story from Egbert to the Norman Conquest. Mrs. Green completed the book.

Domesday Book and Beyond. By F. W. Maitland. 540 pages. Maps. Cambridge Univ. Press 15s.
An example of the learned but illuminative work of the late Professor Maitland, a historian whose perception amounted to genius.

Feudal England. By J. H. Round. 603 pages. Allen & Unwin .. .. 12s. 6d.
An important work for advanced students by one of the most original and capable historians.

English Wayfaring Life in the Middle Ages. By J. J. Jusserand. 451 pages. Fisher Unwin 2s. 6d.
A delightful book of the road, picturing the conditions and accompaniments of travel, as seen through the researches of a distinguished modern French writer and diplomat.

The History of Edward the Third. By James MacKinnon. 645 pages. Longmans .. 18s.
A notable history of one of the longest and most eventful reigns in the annals of England, written with careful reference to Scottish and French, as well as English, points of view.

Hero Myths and Legends of the British Race. By M. J. Ebbutt. Illustrated. Harrap 7s. 6d. net
The stories of legendary British heroes from Beowulf to Robin Hood are here brightly retold, and beautifully and copiously illustrated by brilliant artists. A charming book.

In Feudal Times. By E. M. Tappan. Harrap 5s.
A bright and well-illustrated picture of the manner of life and habits of thought of the people who lived between the eight and fifteenth centuries. The writer chooses the customs most characteristic of the times described, and traces each custom when it was at its height. The illustrations are largely taken from contemporary manuscripts. An attractive and informing book.

English Monastic Life. By Cardinal Gasquet. Methuen .. .. 7s. 6d. net
A full description of the mediæval monastic life by the ablest Catholic historian of our day. The illustrations are numerous and genuinely illustrative. A complete list of English religious houses is given.

English Monasteries. By A. H. Thompson. Cambridge University Press .. .. .. 1s. net
A brief account of the monastic life of the English religious orders, forming an excellent groundwork of knowledge for anyone visiting the ruins of English monasteries.

Old Country Life. By S. Baring Gould. Methuen 6s.
No one knows the country life of England better than the Rev. Sabine Baring Gould, and in this book he is at his best in passing it before our eyes in review. Old county families, country houses, country parsons, country roads, types of servants, village bards and musicians, are some of the subjects of easy and appreciative chat; and the numerous illustrations are delightful, whether they portray old things or old people.

England in the Age of Wycliffe. By G. M. Trevelyan. 396 pages. Maps. Longmans .. .. 6s. net
A social and religious survey of England at the time when thought began to stir after the numbness of the Middle Ages. Sound work, and popular.

England Under the Stuarts. By G. M. Trevelyan. 582 pages. Maps. Methuen .. 10s. 6d. net
A comparison of the social structure and common thought of England with that of Continental peoples of the same period, as an explanation of how the modern system of government in England was begun, and gave a lead to the world. A thoughtful and suggestive work.

Town Life in the Fifteenth Century. By Mrs. J. R. Green. 2 vols. Macmillan .. .. 20s. net
A valuable contribution, from original researches, to the preservation for posterity of the ordinary life of the past. Mrs. Green served an apprenticeship to historical inquiry while helping her husband in his famous works.

The Reign of Henry VII. By A. F. Pollard. 3 vols. Longmans .. .. 10s. 6d. net each
The extremely important reign of Henry VII. is here presented from contemporary sources, with narrative extracts, selected, arranged, and introduced by one of the most competent historians.

History of the Great Civil War. By S. R. Gardiner. 4 vols. 54 maps and plans. Longmans 20s. net
The inclusive dates of the period under survey are 1642–1649. The book is a fine example of historical writing based on original research, and shaped by fairness of mind and the faculty of wise selection.

History of the Commonwealth and Protectorate. By S. R. Gardiner. 4 vols. Longmans .. 20s. net
The last work of a historian of unsurpassed industry and fairness, with a fine power of lucid exposition.

History of England from the Accession of James II. By Lord Macaulay. 2 vols. Longmans .. 5s.
The brilliant fragment in which Macaulay showed how fascinating historical writing might be made. Everyone now sees the literary artifices by which the historian worked up his effects, and knows that his bias must be constantly allowed for; but, none the less, the history is a great book.

The Union of England and Scotland. By James MacKinnon. 542 pages. Longmans 10s. 6d. net
An original book of much value, tracing the Union of Scotland and England as it appeals primarily to Scottish observation—a useful corrective.

History of England in the Eighteenth Century. By W. E. H. Lecky. 12 vols. Longmans. 2s. 6d. each. Lecky's method is to discuss historical events with special reference to their lasting interest, rather than to present them in a plain, informational form. His mellowed judgment expressed itself with a graceful dignity. No true student of the eighteenth century can afford to neglect his work.

The English in Ireland in the Eighteenth Century. By J. A. Froude. 3 vols. Longmans .. 10s. 6d. An illuminative sketch of one of the most sorrowful periods of Irish history, by an observer whose attitude is that of complete detachment from modern controversial prejudices.

A Journal of the Reigns of George IV., William IV., and Victoria. By Charles C. F. Greville. 8 vols. Longmans .. .. .. 3s. 6d. each vol. Greville was Clerk to the Council, and had many opportunities of seeing the inside working of politics. His Diary, kept for the forty years ending in 1860, was edited by the Editor of the "Edinburgh Review." Greville had a happy facility in sketching a portrait in words. He was clever without a purpose.

History of England from 1815 to 1838. By Sir Spencer Walpole. 6 vols. Longmans. 6s. each Has been said to "fill with distinguished merit a vacant space in the history of our country." Four further volumes, under the title "The History of Twenty-Five Years," deal with the years 1856 to 1880.

A History of Our Own Times. By Justin McCarthy. 5 vols. Chatto .. .. 6s. each vol. A pleasantly written narrative of the first sixty years of the reign of Queen Victoria. Invaluable as a readable introduction to modern politics. Saturated throughout with Irish amiability. A condensed edition is published in one volume at 2s. 6d.

A History of Modern England. By Herbert Paul. 5 vols. Macmillan. .. 8s. 6d. net per vol. The period covered by this incisively written History is from 1846 to 1894. The tone of the book is that of well-weighed judgment, and not of glorified journalism.

A Short History of the Scottish People. By D. Macmillan. Hodder & Stoughton. 10s. 6d. net. A good general History of Scotland, glancing broadly over the whole subject.

History of Scotland to 1910. By P. Hume Brown. Cambridge University Press .. 13s. 6d, net. Covers Scottish history from the earliest times to the year 1910. A careful and temperate survey, drawing facts from the most recently discovered knowledge. The author is the Historiographer-Royal for Scotland.

Asia

The Indian Empire: Its History, People, and Products. By Sir W. W. Hunter. Smith, Elder. 28s. A comprehensive survey of the past and present of our Asiatic compatriots, by the writer who has perhaps known the country better than any other British historian.

The Indian Mutiny of 1857. By G. B. Malleson. 435 pages. Illustrations. Seeley .. 5s. An excellent summary account of the great Mutiny, its causes, course, and results.

The Story of Old Japan. By J. H. Longford. 409 pages. Chapman .. .. 6s. A useful compendium of Japanese history, by a writer who has a thorough personal knowledge of the land, people, and language.

The Civilisation of China. By Herbert A. Giles. 253 pages. Williams & Norgate .. .. 1s. net In this work the Professor of Chinese at Cambridge, who was formally British consul at Mingpo, gives a most interesting account of the Chinese people, their customs, beliefs, laws, and family life, showing the real nature of a great people, and dissolving many false ideas still to some extent prevalent.

Africa

The Opening Up of Africa. By Sir H. H. Johnston. 256 pages. Williams & Norgate .. .. 1s. net A remarkable example of compression of information, ethnographical, historical, and, to a less extent, modern. The subject is peculiarly the writer's own. In every chapter the book shows personal knowledge.

History of the Colonisation of Africa. By Sir H. H. Johnston. Maps. Cambridge Univ. Press. 8s. net. A larger and more elaborate summary of the movements of peoples on Africa than that given in Sir Harry Johnston's Home University Library volume.

The Moorish Empire. By Budgett Meakin. 599 pages. Illus. Allen & Unwin .. .. .. 15s. The writer of this historical epitome was the editor of a newspaper published in Morocco, and travelled extensively in the lands held by the Moors. The style is popular, but there is considerable evidence of research in the book.

The Making of Modern Egypt. By Sir Auckland Colvin. Nelson .. .. 1s. net An account of the regeneration of Egypt by British justice in governing the country. An interesting introduction to later developments.

Modern Egypt. By Lord Cromer. Map. Macmillan .. .. 7s. 6d. net In this volume the British Agent who was most intimately concerned in bringing just government to the Egyptian people tells the history of the country for the twenty years that preceded his retirement, and traces the beneficent effects of British rule. The world has never known a more striking instance of the possible influence of systems of government on national prosperity.

America

History of the Conquest of Mexico. By W. H. Prescott. 3 vols. Bell. .. .. 10s. 6d. This was the second of Prescott's four great Histories. His style of writing lends itself to a romantic narration. The story is told once for all. In Everyman's Library the cost of the book is 2s.

History of the Conquest of Peru. By W. H. Prescott. 480 pages. Routledge .. .. .. 3s. 6d. The third great work of the American historian. Careful research provides the material for brilliant narration.

The American Revolution. By Sir George O. Trevelyan. 4 vols. Longmans. 5s. net each vol. Sir George Trevelyan has shown again and again that the spirit of his uncle Macaulay has descended on him as an enthusiastic historian, while his style as a writer avoids the Macaulay mannerisms. This sketch of the American Revolution will retain a classical value. The book is completed in two volumes, 7s. 6d. each net, under the title "George the Third and Charles Fox."

The South American Republics. By Thomas C. Dawson. 1067 pp. 2 vols. Putnams .. 12s. In this book a subject on which the Old World is generally ignorant—the history and development of the countries of South America—is very usefully illuminated.

CIVIL ENGINEERING

SURVEYING

Surveying and Levelling Instruments. By W. F. Stanley. (Spon.) 7s. 6d. net.
Land Surveying and Levelling. By A. T. Walmisley. (Spon.) 6s. net.
Surveying and Surveying Instruments. By G. A. T. Middleton. (Spon.) 5s.
Practical Surveying. By G. W. Usill and A. Beazeley. (Lockwood.) 7s. 6d. net.
Field Work and Instruments. By A. T. Walmisley. (Spon.) 5s. net.
A Treatise on Surveying. By G. T. Middleton, O. Chadwick, and Col. J. du T. Bogle. Two vols. (Spon.) 10s. 6d. each.
Surveying. By J. Whitelaw. (Lockwood.) 10s. 6d. net.
Preliminary Survey and Estimates. By T. G. Gribble. (Longmans.) 7s. 6d.
A Handbook of Theodolite Surveying and Levelling. By Prof. J. Park. (Griffin.) 10s. 6d. net.
A Handbook of Formulæ, Tables, and Memoranda for Architectural Surveyors. By J. T. Hurst. (Spon.) 5s. net.

VARIETIES OF CONSTRUCTION

A Manual of Civil Engineering. By Prof. Rankine. (Griffin.) 16s.
Civil Engineering as Applied in Construction. By L. F. Vernon-Harcourt. (Longmans.) 16s. net.
Engineering Construction in Steel and Timber. By W. H. Warren. (Longmans.) 18s. net.
Civil Engineering Types and Devices. By T. W. Barber. (Lockwood.) 8s. 6d. net.
Strains in Ironwork. By H. Adams. (Spon.) 5s.
The Stresses in Framed Structures. By A. J. du Bois. (Chapman & Hall.) 42s. net.
Stresses in Simple Trusses. By M. Merriman and H. S. Jacoby. (Chapman & Hall.) 10s. 6d. net.
Graphic Statics. By M. Merriman and H. S. Jacoby. (Chapman & Hall.) 10s. 6d. net.
Higher Structures. By M. Merriman and H. S. Jacoby. (Chapman & Hall.) 10s. 6d. net.
The Design of Structures. By S. Anglin. (Griffin.) 16s.
A Practical Treatise on Bridge Construction. By T. Claxton Fidler. (Griffin.) 30s.
An Introduction to the Design of Beams. By W. H. Atherton. (Griffin.) 6s. net.
Strength of Materials. By A. Jamieson. (Griffin.) 5s.
Theory of Structures. By A. Jamieson. (Griffin.) 5s.

REINFORCED CONCRETE

Reinforced Concrete Construction in Theory and Practice. By H. Adams and E. R. Matthews. (Longmans.) 10s. 6d. net.
Reinforced Concrete. By C. F. Marsh and W. Dunn. (Constable.) 31s. 6d. net.
Reinforced Concrete Design Simplified. By J. C. Gammon. (Lockwood.) 10s. 6d. net.
Manual of Reinforced Concrete and Concrete Block Construction. By C. F. Marsh and W. Dunn. (Constable.) 7s. 6d. net.
Concrete-Steel. By W. N. Twelvetrees. (Spon.) 6s.
Concrete Steel Buildings. By W. N. Twelvetrees. (Spon.) 12s. net.
Practical Design of Reinforced Concrete: Beams and Columns. By W. N. Twelvetrees. (Spon.) 6s. net.
Treatise on Concrete, Plain and Reinforced. By F. W. Taylor and S. E. Thompson. (Chapman & Hall.) 21s. net.
Concrete, Plain and Reinforced. By J. S. Trautwine. (Chapman & Hall.) 8s. 6d. net.
Calcareous Cements. By G. R. Redgrave and C. Spackman. (Griffin.) 15s. net.
Portland Cement. By D. B. Butler. (Spon.) 16s.

ROADS

Road Making and Maintenance. By T. Aitken. (Griffin.) 21s. net.
Modern Road Construction. By F. Wood. (Griffin.) 4s. 6d. net.
Dustless Roads. Tar Macadam. By J. W. Smith. (Griffin.) 10s. 6d. net.
The Making of Highroads. By A. F. Carey. (Lockwood.) 2s. 6d. net.
Roads: Construction and Maintenance. By A. Greenwell and J. V. Elsden. (Whittaker.) 5s. net.

BRIDGES

The Design of Simple Steel Bridges. By P. O. G. Usborne. (Constable.) 12s. 6d. net.
Bridge Design. By M. Merriman and H. S. Jacoby. (Chapman & Hall.) 10s. 6d. net.
The Anatomy of Bridge Work. By W. H. Thorpe. (Spon.) 6s. net.
Steel Bridge Designing. By M. B. Wells. (Spon.) 12s. 6d. net.
A Practical Treatise on Bridge Construction. By T. C. Fidler. (Griffin.) 30s.
Reinforced Concrete Bridges. By F. Rings. (Constable.) 21s. net.

RAILWAYS AND TRAMWAYS

Railway Construction. By W. H. Mills. (Longmans.) 18s. net.
Railway Appliances. By Sir J. W. Barry. (Longmans.) 4s. 6d. net.
Electric Railway Engineering. By F. H. Parshall and H. M. Hobart. (Constable.) 42s. net.
Single-phase Electric Railways. By E. Austin. (Constable.) 21s. net.
Overhead Transmission Lines and Distributing Circuits. By B. F. Kapper. (Constable.) 16s. net.
Electric Traction. By J. H. Rider. (Spon.) 10s. 6d. net.
The Inspection of Railway Material. By G. R. Bodmer. (Whittaker.) 4s. 6d. net.
Tunnelling. By C. Prelini. (Lockwood.) 16s. net.
Tunnel Shields and the use of Compressed Air in Subaqueous Works. By W. F. Copperthwaite. (Constable.) 31s. 6d. net.
Light Railways at Home and Abroad. By W. H. Cole. (Griffin.) 16s.
Midland Railway. By F. S. Williams. (Bentley.) 12s.
The Railways of England. By W. M. Ackworth. (Murray.) 12s.

WATER SUPPLY

Rainfall Reservoirs and Water Supply. By Sir A. R. Binnie. (Constable.) 8s. 6d. net.
Water and Its Purification. By S. Rideal. (Lockwood.) 9s. net.
Water Supplies, their Purification, Filtration, and Sterilization. By S. Rideal and E. R. Rideal. (Lockwood.) 7s. 6d. net.
Reservoirs for Irrigation, Water Power, and Domestic Water Supply. By J. D. Schuyler. (Chapman & Hall.) 25s. 6d. net.
Manual of Irrigation Engineering. By H. M. Wilson. (Chapman & Hall.) 17s. net.
Irrigation: its Principles and Practice. By Sir H. Brown. (Constable.) 16s. net.

SEWERAGE

Sanitary Engineering with Respect to Water Supply and Sewage Disposal. By L. F. Vernon-Harcourt. (Longmans.) 14s. net.
Sewerage of Sea Coast Towns. By H. C. Adams. (Lockwood.) 5s. net.

Sewage and Bacterial Treatment of Sewage. By S. Rideal. (Sanitary Publishing Co.) 16s.
Modern Methods of Sewage Purification. By G. B. Kershaw. (Griffin.) 21s. net.
Practical Sanitation. By G. Reid. (Griffin.) 6s.
Sanitary Engineering. By F. Wood. (Griffin.) 8s. 6d. net.
Sewerage Systems. By H. S. Watson. (Lockwood.) 10s. 6d. net.

REFUSE

Modern Destructor Practice. By W. F. Goodrich. (Griffin.) 15s. net.
A Text Book on Trade Waste Waters. By H. M. Wilson and H. T. Calvert. (Griffin.) 18s. net.
Trades Waste. By W. Naylor. (Griffin.) 21s. net.
Smoke Prevention and Fuel Economy. By J. B. C. Kershaw and W. H. Booth. (Constable.) 6s. net.

HYDRAULICS

Hydraulic Machinery. By R. G. Blaine. (Spon.) 10s. 6d. net.
Water or Hydraulic Motors. By P. R. Björling. (Spon.) 9s.
Practical Hydraulics. By T. Box. (Spon.) 5s. net.
A Treatise on Hydraulics. By M. Merriman. (Chapman & Hall.) 17s. net.
Hydraulics. By A. Jamieson. (Griffin.) 5s.
Pipes and Tubes. By P. R. Björling. (Whittaker.) 3s. 6d. net.
Hydraulic Motors and Turbines. By G. R. Bodmer. (Whittaker.) 12s. 6d. net.
Calculations in Hydraulic Engineering. By T. C. Fidler. Two vols. (Longmans.) 6s. 6d. and 7s. 6d.
Hydraulics. By S. Dunkerley. Two vols. (Longmans.) 10s. 6d. net each.
Hydraulic Power and Hydraulic Machinery. By H. Robinson. (Griffin.) 25s. net.
Hydraulic Rams. By J. W. Clarke. (Batsford.) 3s.
A Practical Manual of Tides and Waves. By W. H. Wheeler. (Longmans.) 7s. 6d. net.
Tidal Rivers. By W. H. Wheeler. (Longmans.) 16s.
Coast Erosion and Protection. By E. R. Matthews. (Griffin.) 10s 6d. net.

PUMPS

Pumps. By P. R. Björling. (Spon.) 7s. 6d. net.
Practical Handbook on Pump Construction. By P. R. Bjorling. (Spon.) 3s. 6d. net.
Pumps and Pumping Machinery. By F. Colyer. 2 vols. (Spon.) 10s. 6d. net each.
Pump Details. By P. R. Björling. (Spon.) 7s. 6d.
Pumps and Pump Motors. By P. R. Björling. 2 vols. (Spon.) 30s. net.
Pumping Machinery. By H. Davey. (Griffin.) 21s.

HARBOURS AND DOCKS

Principles and Practice of Harbour Construction. By W. Shield. (Longmans.) 15s. net.
Dock Engineering. By B. Cunningham. (Griffin.) 30s. net.
Harbour Engineering. By B. Cunningham. (Griffin.) 16s. net.
The Dock and Harbour Engineer's Reference Book. By B. Cunningham. (Griffin.) 7s. 6d. net.

TRANSIT

Embracing Aviation, Shipbuilding, and Motoring.

(See under Civil Engineering for Railways.)

Motors and Motoring. By Prof. Spooner. (Jack.) 2s.
Motoring for the Moderate Incomes. By H. R. Reynolds. (Arnold.) 1s.
Text-Book of Motor-Car Engineering. By H. R. Reynolds. 2 vols. (Constable.) 16s.
Petrol Motors and Motor-Cars. By T. Hyler White. (Longmans.) 4s. 6d. net.
Practical Motor-Car Repairing. By E. W. Walford. (Percival Marshall & Co.) 1s. net.
Motor Cyclists' Handbook. By "Phœnix." (P. Marshall & Co.) 2s. net.
Motor Pocket-book. By M. O'Gorman. (Constable.) 7s. 6d. net.
Electric Lighting and Starting for Motor-Cars. By Harold H. K. Cross. (Crosby, Lockwood.) 3s. 6d.
Motor-Car Construction. By R. W. A. Brewer. (Crosby, Lockwood.) 5s.
Carburation. By R. W. A. Brewer. (Crosby, Lockwood.) 5s.
Practical Design of Motor Cars. By James Gunn. (Arnold.) 10s. 6d.
A Manual of Petrol Motors and Motor-Cars. By F. Strickland. (Charles Griffin.) 18s.
Electrical Ignition. By M. A. Codd. (Spon.) 3s.
Dernhardt-Scholmann Technical Dictionary in Six Languages—Motor Vehicles. (Constable.) 12s.
Motor Manual. (Temple Press.) 1s. 6d.
Motor Bodies & Chassis. By J. H. Butler. (Harper.) 6s.

AVIATION

The Aeroplane. By T. Hubbard, J. H. Ledeboer, and C. C. Turner. (Longmans.) 2s. 6d. net.
The Mechanics of the Aeroplane. By Commander Duchêne. (Longmans.) 7s. 6d. net.
Flying. By G. Hamel and C. C. Turner. (Longmans.) 2s. 6d. net.
The Aeroplane Portfolio. Nine sheets of scaled drawings of leading machines, with descriptions. (P. Marshall & Co.) 1s. net.
Aerial Flight. By F. W. Lanchester. 2 vols. (Constable.) 42s. net.
Art of Aviation. By C. W. A. Brewer. (Lockwood.) 5s. net.

SHIPBUILDING

Naval Architecture. By T. H. Watson. (Griffin.) 15s. net.
War Ships. By E. L. Attwood. (Griffin.) 10s. 6d.
Textbook of Theoretical Naval Architecture. By E. L. Attwood. (Griffin.) 7s. 6d. net.
Practical Shipbuilding. By A. C. Holmes. 2 vols. (Griffin.) 30s. net.
Cold Storage, Heating, and Ventilating on Board Ship. By S. F. Walker. (Constable.) 8s. net.
Naval Architects' and Shipbuilders' Pocket-book. By C. Mackrow. (Lockwood.) 12s. 6d. net.
Civil Engineers' Pocket-book. By J. C. Trautwine. (Chapman & Hall.) 21s. net.
A New Civil Engineers' Pocket-book. Edited by M. Merriman. (Chapman & Hall.) 21s. net.

ENGLISH LITERATURE

Books of all Periods, with a Comprehensive Chronology and a List of Anthologies.

History of English Literature. By H. A. Taine. 4 vols. Chatto and Windus .. .. 8s. net
A very readable work, but written to prove and illustrate certain preconceived ideas. The author, for example, attributes certain qualities to the English people, and then goes to the books of the race to find proofs of the presence of these qualities. His criticism consequently has an air of criticism for a purpose, and does not always arise naturally.

A Short History of English Literature. By George Saintsbury. Macmillan .. .. .. 8s. 6d.
This standard work shows the literature of our country in relation to the contemporary history of the nation and world.

The Cambridge History of English Literature. 16 vols. Cambridge University Press. £6 the set. This is the most ambitious book on English literature ever published. It aims at the discussion of each period, and each distinctive movement in each period, by a writer who has devoted special study to the subject. Nothwithstanding palpable inequality in the styles of men who know and can write clearly, and men who know and tell their story with a woolly indefiniteness, and in spite of some overlapping, the work as a whole reaches a very high level of ability and interest. It is not intended for beginners, but for readers who know the general trend of the national literature. There is an almost exhaustive bibliography, laying the literatures of the modern world under contribution,

History of English Literature. By Andrew Lang. Longmans .. .. 6s.
A readable sketch of the story of English literature, beginning with Beowulf and ending with Lecky. Both biographical and critical. Strong in the romantic periods.

History of English Poetry. By W. J. Courthope. 6 vols. Macmillan .. .. 60s.
This is the standard history of English verse—the most ambitious work of its kind, and it cannot be neglected by the reader whose study is thorough and consecutive.

The English Poets. Edited by Thomas H. Ward. 4 vols. Macmillan .. .. 31s.
The best of the extended selections of English verse. The general introduction is by Matthew Arnold, and the chapters of criticisms reach a high standard of interest and value.

Chambers's Cyclopædia of English Literature. 3 vols. Chambers .. .. .. 31s. 6d. net.
This invaluable book, edited by Dr. David Patrick, and written by many able critics, sketches periods of literature in articles, gives the lives of all prominent authors, and a critical estimate of their writings, and includes many illustrative extracts from the works of standard writers. It is by far the best book of its kind. The illustrations include a large gallery of portraits.

English Literature. By Stopford Brooke. Macmillan .. .. 3s. 6d. and 1s.
Quite the best general sketch of English literature from the first till 1832. The writer is himself a poet, and a delightful prose stylist. His criticisms are judiciously sympathetic. Originally this book was published as a Literature "Primer," and in the same series is an excellent compendium of Shakespearian criticism by Professor Dowden, and one equally good on Chaucer by Professor Pollard.

A School History of English Literature. By Elizabeth Lee. 3 vols. Blackie .. .. 1s. 6d.
A biographical account of writers of English, with admirably chosen brief extracts and some criticism. The best of the books written for secondary school use. It combines abundant facts with an appreciation of the spirit of the best literature.

Early English Literature. By Stopford Brooke. Two vols. Macmillan .. .. 20s. net
This brilliant book brings along the story of Anglo-Saxon literature to the reign of Alfred. It contains charming verse translations of the fragments of Anglo-Saxon poems that have been preserved—translations that only a poet could have made.

Early English Literature. By B. T. Brink. Translated by H. M. Kennedy. 2 vols. Bell. 3s. 6d. each
A scholarly work, which advanced students will do well to consult. A standard book.

A History of English Criticism. By George Saintsbury. Blackwood .. .. .. 7s. 6d. net
This is an adapted reprint of the English part of Professor Saintsbury's "History of Criticism and Literary Taste in Europe," a standard work.

English Literature from the Norman Conquest to Chaucer. By W. H. Schofield. Macmillan. 7s. 6d.
One of the most able and best-systematised studies of the literature of the period, and of subsequent times, into which mediæval styles were continued.

English Literature from the Beginning to the Conquest. By Stopford Brooke. Macmillan. 7s. 6d.
An invaluable sketch of Anglo-Saxon literature by a fine critic who is an expert Anglo-Saxon scholar. The book on its subject.

A History of Elizabethan Literature. By George Saintsbury. Macmillan .. .. 7s. 6d.
A very able review of the Elizabethan period by a writer who specially delights in its exuberance.

The English Novel in the Time of Shakespeare. By J. J. Jusserand. Fisher Unwin .. 7s. 6d.
M. Jusserand brings forward the evidence that before Shakespeare, and contemporaneously with him, books were being written in English that might properly be called novels. Most of the early dramatists wrote such books.

Essays on Mediæval Literature. By W. P. Ker. Macmillan .. .. 5s. net
Illuminating discussion by an author who is master of his period and has the advantage of a forceful style not unrelieved by humour.

Poets and Poetry. By John Bailey. Clarendon Press .. .. 5s.
A book that introduced to the world of letters one of the strongest, breeziest, and sanest of critics.

Handbooks of English Literature. Edited by J. W. Hales. 11 vols. Bell .. .. 3s. 6d. each
A very useful series under experienced editorship. Nine Ages are covered, namely, the Chaucerian and Transition Ages, in three vols., by F. J. Snell Shakespeare, two vols., by Thomas Seccombe and J. W. Allen—exceptionally well done; Milton, by J. H. B. Masterman; Dryden, by Dr. Richard Garnett; Pope, by John Dennis; Johnson, by Thomas Seccombe; Wordsworth, by C. H. Herford; and Tennyson, by Hugh Walker.

Essays in Criticism. By Matthew Arnold. 2 vols. Macmillan, 4s. each; Dent, 1s. each.
Matthew Arnold did much to establish the art of critical appreciation towards the close of the Victorian period, and these volumes conserve his influence and illustrate his style. His English subjects include Milton, Gray, Keats, Wordsworth, Byron, and Shelley.

A Guide to the Best Historical Novels and Tales. By Jonathan Nield. Elkin Matthews 8s. net.
The historical tales are arranged in chronological order, and are commented on judiciously and with interest. An old book that well deserves to keep its place.

Hours in a Library. By Sir Leslie Stephen. 3 vols, Smith, Elder .. .. .. 3s. 6d. per vol.
The essays that make up these volumes cover a very wide range of literary subjects. Defoe, Richardson, Hawthorne, Scott, De Quincey, Johnson, Crabbe, Hazlitt, Disraeli, C. Brontë, Kingsley, Godwin, Shelley, Gray, Sterne, G. Eliot, Carlyle, and Coleridge are among the writers dealt with. Stephen never hesitated to put the warts and freckles into his pictures.

Essays. By Augustine Birrell. 2 vols. Duckworth .. .. 2s. 6d. net. each.
The charming literary essays, originally published by Mr. Augustine Birrell as "Obiter Dicta," in two series, and as "Men, Women, and Books" and "Res Judicatæ," in two more volumes, are now issued by Messrs. Duckworth, in two volumes, at half-a-crown each. All Birrell's criticisms are suggestive and stimulating as well as amusing.

Shakespeare Personally. By David Masson. Smith, Elder .. .. 6s. net
For thirty years Professor David Masson lectured on Shakespeare as part of his professorial work. In this volume his daughter brings his lectures together. The general effect of the book is to suggest that we know more about Shakespeare than is commonly understood to be known, and that his individuality may be pretty accurately divined. A suggestive study.

Poets and Poetry of the Nineteenth Century. 12 vols. Routledge .. .. .. 1s. 6d. net
Autobiographical sketches and criticisms of all the best-known poets and poetesses of the century, with selections from their works. It is more fully representative than any other selection from the writers of the period included, and fills a distinct place of its own, but the form of the volumes is faulty, and the absence of a general index, or of numbers or dates to volumes, makes the work difficult to consult.

Principles of Biography. By Sir Sidney Lee. 54 pages. Cambridge University Press .. 1s. 6d. net
A lecture by the Editor of the "Dictionary of National Biography" on the writing of biography. The lecturer examines the methods that lead to success and those that lead to failure.

Studies of a Biographer. By Sir Leslie Stephen. 4 vols. Duckworth .. .. 2s. 6d. net each
Essays on the lines of "Hours in a Library." Johnson, Gibbon, Arthur Young, Wordsworth, Scott, Matthew Arnold, Jowett, O. W. Holmes, Tennyson, Browning, Ruskin, Bagehot, Huxley, Froude, Shakespeare, Southey, Milton, Emerson, Trollope, and Stevenson are the chief characters in a delightful book.

Literary Studies. By Walter Bagehot. 3 vols. Longmans, 3s. 6d. each; 2 vols., Dent, 1s. each.
A man of powerful original mind and fearless utterance, Walter Bagehot was as eminent in the literary world as in finance and politics. His criticisms keep the reader constantly expectant by their wealth of thought. Hartley Coleridge, Shakespeare, Gibbon, Shelley, Macaulay, are notable subjects in these volumes.

English Prose. Edited by Sir Henry Craik. 5 vols. Macmillan .. .. 38s. 6d.
The standard "selection" book for English prose passages. To each period there is an introduction.

Milton. By Sir Walter Raleigh. Arnold .. 6s.
A luminous criticism by a writer always fascinating.

Milton's Prosody. By Robert Bridges. Frowde. 5s. net
An examination of Milton's writing by the Poet-Laureate in a strain that is a revelation to many. It is an appreciation by a poet of a poet who felt beyond all other English poets the melody of words.

Six Essays on Johnson. By Sir Walter Raleigh. Clarendon Press .. .. 5s. net
The student of Johnson's writings cannot afford to neglect these brilliant sketches of Johnson and his work by a great critic.

The English Novel. By Sir Walter Raleigh. John Murray .. .. 2s.
A critical and historical study of English fiction before Scott. Fresh and thought-provoking.

Studies in the Literary Relations of England and Germany in the Sixteenth Century. By C. H. Herford. Cambridge University Press .. .. 9s.
A careful study, in high repute among critics who make a special study of the period.

The Mabinogion: Welsh Romances. 374 pages. Illustrated. Nutt .. .. .. 1s. 6d. net
This is the most attractive edition of the Welsh mediæval poetic cycle. The translator is Lady Charlotte Guest.

Critical Miscellanies. By Viscount Morley. 4 vols. Macmillan. 3 vols, 4s. net each; one, 7s. 6d. net
Fine examples of responsible criticism, written in a style that makes literature. The subjects include Carlyle, Byron, Macaulay, Emerson, Mill, George Eliot, W. R. Greg, Machiavelli, and Lecky. In volume three is a lecture on Popular Culture, the most eloquent of Morley's writings.

Studies in Literature. By Viscount Morley. 347 pages. Macmillan .. .. .. 4s. net
This volume includes a valuable address on "The Study of Literature." It also reprints the fine introduction to Macmillan's edition of Wordsworth.

My Study Windows and the English Poets. By James Russell Lowell. Walter Scott. 1s. net each
Not only was Lowell a poet of varied power—from passionate imagination to the broadest humour—but he was a critic of most luminous mind, with a remarkable command of expressive metaphor. His essay on Chaucer is masterly. Some of his judgments have been hotly challenged, partly because he has patience with the pedantry that would find literature in what is generally unreadable.

The Principles of Criticism. By W. Basil Worsfold. 264 pages. Allen & Unwin. .. 3s. 6d. net
A wide survey of literature, ancient and modern, with extracts, with a view to assist in the formation of sound judgment in the reader.

Judgment in Literature. By W. Basil Worsfold. 105 pages. Dent .. .. 1s. net
A useful little book, dividing literature into styles and methods, and guidance in forming opinions.

Studies in Poetry. By Stopford A. Brooke. 2 vols. Duckworth .. .. .. 2s. 6d. each net
Dr. Stopford Brooke's first volume contains essays on Blake, Scott, Shelley, and Keats; and his second volume, under the title "A Study of Four Poets," estimates Clough, Arnold, Rossetti, and William Morris. Everything written in literature by this polished critic deserves attention, alike because of what is said and how it is said.

Style. By Sir Walter Raleigh. 129 pages. Arnold. 5s.
A brilliant discussion of a subject that almost evades definition. Professor Raleigh's definition of style is "the gesture of the mind."

The Breakfast Table Series. By Oliver Wendell Holmes. Many editions, publishers, and prices.
Holmes's "Autocrat of the Breakfast Table," "Professor at the Breakfast Table," and "Poet at the Breakfast Table" appear quite properly in every cheap list of classics. It has been said that no books afford a better test of literary feeling. They were written in the order given above, and it is the true order of their literary value. The tale element, delicately developed, is strongest in the "Professor." In the "Poet" the writing thins into expansiveness.

The Making of English. By H. Bradley. Macmillan .. .. 4s. 6d.
A sketch of changes that have taken place in the language, the sources of its expansion, and the changes in words. Learned, though readable.

Literatures of the World. Edited by Edmund Gosse. 14 vols. Heinemann .. .. 6s. each vol.
The chief literatures of the world are succinctly reviewed and their distinctive features explained by well-known critics. The literatures included are Ancient Greece (by Dr. Gilbert Murray), French (by Edward Dowden), German, English (by Edmund Gosse), Italian (by Dr. Garnett), Japanese, Bohemian, Russian, Sanskrit, Chinese (by H. A. Giles), Hungarian, American (by W. P. Trent), and Arabic.

The Library of Literary History. 10 vols. Fisher Unwin .. .. .. 12s. 6d. net each.
In this series the literatures of India, Ireland, America, Persia (2 vols.), Scotland, the Arabs, France, Russia, and Rome are outlined by experienced writers. The volume on India, by R. W. Frazer, is especially good.

Periods of European Literature. Edited by George Saintsbury. 12 vols. Blackwood. 5s. net each.
An excellent series, tracing the literary developments of Europe in historical sequence. Professor Saintsbury himself writes three of the volumes, including "The Later Nineteenth Century." Other writers are Professor W. P. Ker, F. J. Snell, Professor G. Gregory Smith, David Hannay, Professor H. J. C. Grierson, Professor Oliver Elton, Professor J. H. Miller, Professor C. E. Vaughan, and T. S. Omond.

Shakespeare's Predecessors in the English Drama. By J. Addington Symonds. Smith, Elder. 7s. 6d.
An extremely able writer traces the growth of the drama in England from miracle plays, etc., through the "University Wits," and writers younger than Shakespeare, up to its culmination in him.

English Miracle Plays, Moralities, and Interludes. By Alfred W. Pollard. Clarendon Press. 7s. 6d.
A most valuable book on the plays that preceded the rise of the regular British drama, with interesting specimens and explanations. Professor Pollard is a master of the period concerned.

Specimens of English Dramatists. By Charles Lamb. 2 vols. Dent .. .. 3s. 6d. each.
A charming selection by a writer who, in a lighter way, did almost as much towards securing appreciation of the historical English drama as Coleridge and Hazlitt did in a more formal manner.

Shakespeare: a Critical Study of his Mind and Art. By Edward Dowden. Kegan Paul. .. 12s.
A successful attempt to trace the gradual growth of Shakespeare's power as a dramatist. The sequence of the plays shows, according to Dowden, a mental drama in the poet of surprising interest—a view now generally accepted.

A Study of Shakespeare. By Algernon C. Swinburne. 309 pages. Chatto .. .. 8s.
A delightful general survey of Shakespeare's expanding genius by a writer who was as certainly a master of prose as of verse.

Shakespeare's Heroines. By Mrs. Jameson. 351 pages. Bell .. .. 1s. net.
One of the best examples of the helpful criticism of a past generation. Feminine character is judged with a woman's keen insight.

Characters of Shakespeare's Plays. By W. Hazlitt. Macmillan .. .. .. 3s. 6d. net.
One of the most suggestive of the books elucidating Shakespeare. Holds its own in the midst of criticism.

A History of English Dramatic Literature. By Sir A. W. Ward. 3 vols. Macmillan .. 36s. net
This is the standard work on the English drama. The story closes with the reign of Queen Anne.

Autobiographies and Biographies that are Literature or Literary History.
Charlotte Brontë. By Mrs. Gaskell. Smith, Elder. 2s. 6d.
Byron. By Thomas Moore. Murray. 7s. 6d.
Thomas Carlyle. By J. A. Froude. Longmans. 14s.
Dickens. By John Forster. Chapman. 2s. 6d.
George Eliot. By J. W. Cross. Blackwood. 7s. 6d.

Scott. By J. G. Lockhart. Black. 5s.
Shakespeare. By Sir Sidney Lee. Smith, Elder. 2s. 6d.
Autobiography. Herbert Spencer. Williams. 12s. 6d
Tennyson. By his son. Macmillan. 6s.
Wolsey. By George Cavendish. Routledge. 1s.

Useful Series of Books on Literature

Golden Treasury Series. Macmillan 2s. 6d. net
This handsome series, named originally from Palgrave's delightfully chosen "Golden Treasury of the Best Songs and Lyrical Poems in the English Language," now extended to a second series, and a children's selection, includes some notable selections from the poets.

The Silver Library. Longmans .. .. 3s. 6d.
This extensive library includes, among works of varying literary value, a number that hold a place in literary history,

The Globe Library. 20 vols. Macmillan. 3s. 6d.
This Library, which includes both poetry and prose, is most ably edited and introduced.

Temple Classics. 96 authors. Dent. 1s. 6d. net.
This attractive series includes examples of a very wide range of literature, both in time and country. A feature is the inclusion of Indian epics and poems. The Welsh "Mabinogion" is one of the volumes, and there are many books not found usually in such lists.

English Men of Letters. Old Series. 39 vols. Macmillan. .. .. 1s. 6d.
This is by far the best series of critical literary biographies ever issued. The writers are all authors of mark, working under the general editorship of Viscount Morley. The new series issued more recently receives separate mention.

English Men of Letters. New Series. 26 vols. Macmillan. .. .. 2s. net
The new series of the Men of Letters fully sustains the high standard of the earlier issue. The Shakespeare, Ruskin, and Browning are specially brilliant examples of appreciative criticism.

Modern English Writers. By various authors. 7 vols. Blackwood. .. .. .. 2s. 6d.
The seven writers whose personalities and literary productions are examined in this series are M. Arnold, by George Saintsbury; R. L. Stevenson, by L. C. Cornford; Ruskin, by Mrs. Meynell; Tennyson, by Andrew Lang; Huxley, by Edward Clodd; Thackeray, by Charles Whibley; and Browning, by C. H. Herford.

The Warwick Library. Edited by C. H. Herford. 8 vols. Blackie .. .. 2s. 6d. Each volume deals with the development of some special literary form in English literature, gives specimens, and includes a critical introductions.

Great Writers. Walter Scott. 45 vols. .. 1s. net. These biographies are written for the most part by very capable critics of literature, including Mr. Birrell, Goldwin Smith, William Sharp, Dr. Richard Garnett, Edmund Gosse, Oscar Browning, Austin Dobson, W. L. Courtney, H. W. Nevinson, R. B. Haldane, and Hall Caine.

The Scott Library. Walter Scott. 130 vols. 1s. net. No praise is too high for this well-selected, well-printed series of classical prose writings. Here are some of the books not so readily available in other series: Letters of Burns, Byron, and Lord Chesterfield; examples of Heine's prose (three vols.); Essays of Hume, Leigh Hunt, Dr. Johnson, Cowley, Lowell, Newman, Sainte-Beuve, Schopenhauer, Renan, and Thoreau; Milton's Prose, Malory's "Morte d'Arthur," and Landor's "Imaginary Conversations." From every point of view the series is good and sound at the price.

Temple Dramatists. 30 vols. Dent .. 1s. net. The English authors represented in this series are Marlowe and Fletcher, each by two plays, and Beaumont and Fletcher, Dekker, Farquhar, Greene, Heywood, Kyd, Jonson, Massinger, Otway, Peele, Ford, Udall, and Webster by one. A modern section includes Sheridan, Goldsmith, and Shelley. Three pseudo-Shakespearian plays, "Arden of Faversham," "Edward III.," and "The Two Noble Kinsmen," are included. The plays selected are admirable, including any that once had a great vogue and should be read as a test of passing taste.

Mermaid Series. The Best Plays of the Old Dramatists. 27 vols. Fisher Unwin .. .. 3s. 6d. This unique series, in which the old text is literally reproduced, has engaged the services of many editors, including Swinburne, J. A. Symonds, G. Saintsbury, J. St. Leo Strachey, Wm. Archer, C. H. Herford, Havelock Ellis, Ernest Rhys, Arthur Symons, Edmund Gosse, and G. A. Aitkin. The dramatists presented include Beaumont and Fletcher, Chapman, Congreve, Dekker, Dryden, Farquhar, Ford, Greene, Heywood, Ben Jonson, Marlowe, Massinger, Middleton, Otway, Shadwell, Shirley, Steele, Vanburgh, Webster, and Wycherley. It is the best edition of the dramatists who surrounded Shakespeare and led on into the ultimate decline of the theatre under the Restoration of the Stuarts.

Canterbury Poets. Walter Scott. 109 vols. .. .. 1s. The strong point about these handy little volumes is that they include some poets and selections not readily and cheaply obtainable elsewhere. The weak point is that they are selections, not complete works. Besides the greatest poets, such writers are included as Wm. Blake, Thomas Chatterton, Sydney Dobell, James Hogg, Robert Herrick, Henry Kirke White, Edgar Allan Poe, Wm. Praed, Allan Ramsay, Alexander Smith, and James Thomson. The volume "Sonnets of the Century" has an excellent introductory article on the Sonnet.

Oxford Poets. Clarendon Press .. .. 3s. 6d. The cheapest edition of the poets ever published. About 40 volumes. Nearly all the poets are given in a complete form, carefully edited, with an introduction in some cases. The poets included are M. Arnold, Blake, R. Bridges, E. B. Browning, Robert Browning, W. C. Bryant, Burns, Byron, Campbell, Chaucer, Coleridge, Cowper, Dryden, Emerson, Goldsmith, Mrs. Hemans, Geo. Herbert, Tom Hood, Jean Ingelow, Keats, Keble, Longfellow, Lowell, Milton, Moore, Wm. Morris, Poe, Adelaide Procter, Rossetti, Scott, Shakespeare, Shelley, Southey, Spencer, Tennyson, Thomson, Whittier, and Wordsworth. There are also half a dozen Anthologies of verse and prose in the series.

Useful Series of Books on General Subjects

Eversley Series. Various authors. Macmillan. 4s. net. In this attractive series, bound for the library, are Matthew Arnold's criticisms, poems, discoveries, and lectures, in eight vols.; the works of John Richard Green, in 12 vols.; Huxley's works, in 12 vols.; Kingsley's novels and poems, in 11 vols.; Viscount Morley's works, in 18 vols.; and Wordsworth's poetical works and the Journal of his sister Dorothy, in 10 vols. All these books have a place in the story of our literature, and cannot at present be obtained elsewhere in a complete form.

Home University Library. Williams, Norgate. 1s. net. The literary section of this priceless library includes, at the time of writing, a number of books which may rank as criticisms with those of a far more ambitious exterior. "Dr. Johnson and his Circle" and "Milton," both by John Bailey, are brilliantly fresh and thoroughly sound. "Mediæval Literature," by Professor Ker, and "Modern English Literature," by G. H. Mair, are excellent summaries. Mr. Chesterton's "Victorian Age" is bold and bright. John Masefield's "Shakespeare" deals almost exclusively with the separate plays and not with generalisations. "Great Writers of America" is a straightforward, level-headed summary. J. M. Robertson's "Elizabethan Literature" is one of the strongest books in the list.

Everyman Library. 700 vols. Dent .. 1s. net This fine library contains, besides fiction and poetry, many books essential to the study of English literature. An invaluable collection of books, though some volumes are much below the standard of classical work.

Ancient Classics for English Readers. Edited by W. Lucas Collins. 28 vols. Blackwood. 1s. net A most admirable series, some of the volumes being brilliant examples of compendious writing. The volumes sketch Homer's Iliad, Homer's Odyssey, Herodotus, Cæsar, Virgil, Horace, Æschylus, Xenophon, Cicero, Sophocles, Pliny, Euripides, Juvenal, Aristophanes, Hesiod and Theognis, Plautus and Terence, Lucian, Plato, Livy, Ovid, Catullus, Tibullus and Propertius, Demosthenes, Aristotle, Thucydides, Lucretius, and Pindar; and there is a Greek Anthology.

Foreign Classics for English Readers. Edited by Mrs. Oliphant. 18 vols. Blackwood .. 1s. net This is one of the oldest and deservedly most popular of the literary series which sketch a writer's life and tell his message briefly. The classics included are Dante, Voltaire, Pascal, Petrarch, Goethe, Molière, Montaigne, Rabelais, Calderon, Saint Simon, Cervantes, Corneille, and Racine, Madame de Sévigné, La Fontaine, Schiller, Tasso, Rousseau, and Alfred de Musset.

Philosophical Classics for English Readers. Edited by Prof. Wm. Knight. 15 vols. Blackwood. 1s. net The philosophers represented in the series are Descartes, Butler, Berkeley, Fichte, Kant, Hamilton, Hegel, Leibniz, Vico, Hobbes, Hume, Spinoza, Bacon, and Locke, and each is introduced by a well-known writer, in nearly every case a professor of philosophy. This series gives the simplest of all the summaries of the modern philosophers.

Universal Library. Over 200 vols. Routledge. 1s. net. This Library, originally chosen by Professor Henry Morley, has been much extended. It includes a number of valuable books not found as cheaply elsewhere, as, for example, "Famous Pamphlets," including the one in which Whateley undertook to prove, according to certain popular principles of historical doubt, that there never was a Napoleon.

Popular Library. Routledge .. .. .. 3s. 6d. This collection remains very useful, though it is one of the oldest of its kind. The Library has earned lasting respect by its solid value.

World's Classics. 200 vols. Oxford University Press .. .. 1s. net This series covers a very wide range of literature. Its poetry is in the form of selections. There is a volume of plays by contemporaries of Shakespeare, and the foreign travels of Smollett and of Fielding are included. Æschylus, Aristophanes, Marcus Aurelius, Cervantes, Homer, Le Sage, Machiavelli, Sophocles, Virgil, and Tolstoy are to some extent translated.

Dictionary of National Biography. Smith, Elder. Cheaper edition. 25 vols. £18 15s. This great work takes the foremost place in literary as in general history, its biographical material being indispensable to the student of our literature.

Library of Romance. Seeley .. .. .. 5s. Thirty volumes telling the stories of invention, exploration, travel, science, seagoing, manufacture, aeronautics, missions, mining, plant and animal life, etc. Popular in treatment, and designed primarily for the young.

Story of Exploration Series. Edited by J. Scott-Keltie. Alston Rivers .. .. 4s. 6d. net The regions that provide material for this travel series are Arabia, the South Pole Further India, the St. Lawrence Basin, the Nile,, and Tibet. In each case discovery is traced by a writer with special knowledge.

Social Science Series. Allen & Unwin. 2s. 6d., 3s. 6d., and 1s. net. The series consists of 120 books discussing as many subjects of sociological interest.

New Library of Medicine. Edited by Dr. Saleeby. Methuen .. .. 7s. 6d. net and 10s. 6d. net Nine volumes by well-known doctors, discussing subjects of popular interest, but also of great social importance. Their appeal is to the intelligent public rather than to the specialist.

Progressive Science Series. Murray. 6s. and 9s. net. A valuable series of quite miscellaneous composition, ranging from the Stars to Whales. Among the writers are scientists like Soddy, Loeb, Simon Newcomb, and J. Arthur Thomson.

Medieval Towns. Dent .. .. 3s. 6d. net. In this series thirty-four towns of Europe and the East are sketched in words and illustrated by drawings, the writers all having special qualifications for their work. An excellent scheme, well carried out.

The Nineteenth Century Series. Chambers. 5s. net. Nineteenth-century progress is traced through 25 volumes. Religion, literature, politics, exploration, economics and industry, inventions, military science, naval development, education, temperance, science, are some of the subjects; and as regards place, special attention is paid to the British Isles, the British Empire, and the United States. The authors include such expert writers as Prof. W. P. Trent, T. H. S. Escott, Oscar Browning, Professor J. Arthur Thomson, and William Sharp.

Antiquary's Books. Methuen .. .. 7s. 6d. net. A highly interesting series of well-written books dealing with antiquarian rather than archæological subjects, exclusively within the British Islands.

People's Books. Jack .. .. .. 6d. net. A series, now reaching over a hundred volumes, 109 vols. which aims at bringing the results of modern knowledge within reach of all by summaries from the pens of experienced writers.

A Bibliography of English Literature

LIFE AND MIND

Biology

The Story of Evolution. By J. McCabe. 340 pages. Illustrated. Hutchinson .. .. 7s. 6d. net
A popular and fascinating account of the development of the universe, from the birth of worlds, through the evolution of life, to the dawn of civilisation and the evolution of history. Learned and readable. A comprehensive and reliable summary of our knowledge up to 1912.

Evolution. By Patrick Geddes and J. A. Thomson. 248 pages. Williams & Norgate .. 1s. net
These two authors have collaborated before, as in their famous "Evolution of Sex." Here they give an excellent summary of the principal facts and theories relating to organic evolution.

Evolution, the Master-Key. By C. W. Saleeby. 359 pages. Harper 7s. 6d
Writing in a clear and popular manner, Dr. Saleeby traces the principle of evolution in atoms and stars, living things, in the development of mind, and social affairs and morals. The work is largely based upon the ideas of Herbert Spencer, but is also up to date.

Darwinism and Human Life. By J. Arthur Thomson. 245 pages. Melrose .. .. 5s. net
Darwinism, and an estimate of the present position of the Darwinian theory in relation to the work of Mendel and De Vries. An endeavour is also made to suggest how Darwinism touches everyday life, in farm and garden, in city and empire. Written in a clear and attractive way, and delivered in the form of lectures in South Africa in 1909.

Evolution and the Function of Living Purposive Matter. By N. C. Macnamara. 298 pages. Illustrated. Kegan Paul .. .. 5s.
An endeavour to explain the evolution of and purposive functions performed by those elements of protoplasm essential for purposive, instinctive, and physical phenomena, with a view to realising the importance of heredity in determining the personal character of individuals, and the influence of environment in modifying innate qualities.

The Germ-Plasm: a Theory of Heredity. By A. Weismann. 477 pages. Walter Scott .. 6s.
A translation, by Dr. W. Newton Parker, of the University College of South Wales, of a book which has been built into the very structure of all philosophical thought with regard to heredity during the last twenty years, and which no faithful student of the subject can omit to read first-hand.

Darwinism. By Alfred Russel Wallace. 510 pages. Illustrated. Macmillan .. .. .. 7s. 6d.
This exposition of the theory of natural selection with some of its applications has a special value as being by Darwin's co-discoverer of the principle. The book treats of the struggle for existence; variability in a state of nature and in domesticated animals and plants; natural selection; cross-breeding and hybridisation; origin and uses of colour in animals; mimicry; sexual characteristics; colours of plants; distribution of organisms; geological evidences of evolution; problems of variation and heredity, etc. Of value historically, but needs to be read with more recent works.

The Origin of Species by Means of Natural Selection. By Charles Darwin. 458 pages. Murray .. 1s.
The work that changed the principles and aims of biology and revolutionised the thoughts of man. Setting out from the variation of animals under domestication, Darwin seeks for some natural means of controlling the building up of species from gradually formed varieties. He finds this control in the selective process of the struggle for existence, leading to the survival and multiplication of the fittest.

Man and Woman. By Havelock Ellis. 488 pages. Illustrated. Walter Scott .. .. .. 6s.
Written as a study of "human secondary sexual characters," Dr. Ellis intended this book to be also a more elaborate study of the primary phenomena of sex on the psychological side. Discusses how far sexual differences are artificial, the result of tradition and environment, and how far they are represented in the constitution of the individual.

The Effects of Cross and Self Fertilisation in the Vegetable Kingdom. By Charles Darwin. 487 pages. Murray .. .. 9s.
Most flowers are constructed so as to be fertilised by pollen from another flower. Self-fertilisation leads more easily to production of seeds; cross-fertilisation helps a species of plant to take advantage of slight changes in the conditions of life, making it more adaptable. Darwin found also in his experiments that cross-fertilisation increased the vigour, height, and fertility of plants.

Mendel's Principles of Heredity. By W. Bateson. 430 pages. Illustrated. Cambridge University Press .. .. 12s. net
A full and clear account of the new science of life, based on the recent rediscovery of the neglected work of the greatest of Darwin's contemporaries, the Roman Catholic abbot Mendel. Professor Bateson gives an interesting sketch of Mendel's life, and shows to what results his work is leading.

The Evolution of Sex. By Patrick Geddes and J. Arthur Thomson. Illustrated. Walter Scott. 6s.
A famous book, not to be overlooked by any student of this difficult problem. Its central thesis is "to present an outline of the main processes for the

continuance of organic life," and "to point the way towards the interpretation of these processes in those ultimate biological terms which physiologists are already reaching as regards the functions of individual life—those are the constructive and destructive changes of living matter of protoplasm."

Variation, Heredity, and Evolution. By Robert H. Lock. 334 pp. Illustrated. John Murray. 5s. net
Deals with recent advances in the study of these aspects of biology, and forms an admirable summary of the subject, clearly and interestingly written.

Heredity of Acquired Characters in Plants. By the Rev. G. Henslow. 107 pages. John Murray. 6s. net
The object of this book is to show that evolution, so far as plants are concerned, depends upon the inheritance of acquired characters. It is an attack upon the Neo-Darwinism of Weismann and his followers. A good many botanists are inclined to agree with Professor Henslow's views, but students of animal life still largely hold to Weismann's theory of evolution in the germ-plasm, the body of the parent having no influence.

The Cell in Development and Inheritance. By Edmund B. Wilson. Macmillan .. .. 15s. net
One of the standard works on the study of the living cell. It is for the most part written in highly technical terms, but when a reader has mastered the language he becomes acquainted at first-hand with one of the most famous pieces of research into the mysterious kingdom of life.

A Textbook of Cytology. By Charles E. Walker. 139 pages. Illustrated. Constable .. 7s. 6d. net
The new science of the cell, or the study of living matter in the form which carries with it inheritance and infinite power of development, is here introduced in a general way, unmixed with subsidiary subjects. A useful summary.

The Cell: Outlines of General Anatomy and Physiology. By Oscar Hertwig. Translated by M. Campbell. Illus. G. Allen & Unwin. 7s. 6d. net
A standard book on the subject by the foremost European authority. Much has been done in the twenty years since this translation of Professor Hertwig's work was published, but the book retains its value as an introductory study.

Problems of Life and Reproduction. By Dr. Marcus Hartog. 362 pages. Illustrated. Murray. 6s. net
A general treatise on reproduction, formed from the author's articles in various publications, supplemented and brought up to date. Among the subjects discussed are cellular pedigree, the relation of blood-formation to cell-division, the function of chromatin, the transmission of acquired characters, and mechanism and life. Dr. Hartog is a "reasonable vitalist," opposing mechanistic explanations of life.

Experimental Embryology. By J. W. Jenkinson. 341 pages. Illus. Clarendon Press. 12s. 6d. net
An attempt to discover the causes that determine the form of an organism, and especially the origin of the form in the individual. Has an appreciative chapter on the work of Driesch, but refuses to accept the existence of any self-governing life-force.

Mendelism. By R. C. Punnett. 196 pages. Illustrated. Macmillan .. .. 5s. net
Published in 1905, this little book has continually been extended in size, in order to deal with the progress of the new science of heredity and breeding, until it is now three times as large as it originally was. It deserves its popularity, for it is written in a lucid and broad manner by a first-rate authority.

Heredity. By L. Doncaster. 160 pages. Illustrated. Cambridge University Press .. 1s. net
A sketch of the most important lines of study in relation to heredity that have recently been followed. The reader is taken over the most modern developments by one who regards Mendelism as established, and who is a thoroughgoing disciple of Professor Bateson.

Hereditary Genius. By Sir Francis Galton. 406 pages. Macmillan .. .. 5s. net
This work, by the "father of eugenics," is a statistical consideration of the question whether genius be hereditary or no, and, incidentally, of many kindred questions. Some three hundred families are dealt with, containing between them nearly a thousand eminent men.

Heredity. By J. Arthur Thomson. 621 pages. Illustrated. John Murray .. .. 9s. net
An up-to-date and comprehensive introduction to the study of heredity, followed by a remarkable bibliography and a subject index for enabling the student to pursue inquiry further on particular points. Professor Thomson is admittedly a follower of Weismann. His book gives prominence to conclusions reached first by the microscopic study of the germ-cells; secondly, by the application of statistical methods, and third through experiment.

Variation of Animals and Plants under Domestication. By Charles Darwin. 2 vols. Murray. 5s. net
A collection of facts showing the amount and nature of the changes that plants and animals have undergone under man's dominion.

Darwin and After Darwin. By G. J. Romanes. Three vols. Illustrated. Longmans. 26s. the set
An exposition of the Darwinian theory of the origin of species and the descent of man, by a famous disciple of the master, followed by an instructive discussion of the chief post-Darwinian problems prior to the recovery of Mendel's discoveries and the revival of the theory of evolution by sudden jumps. The volumes are sold separately.

The Descent of Man. By Charles Darwin. 693 pages. Illustrated. John Murray .. 2s. 6d.
The classic work on the history of the human race. Gives evidence of the descent of man from some lower form; indicates the manner of his evolution, and traces his affinities among the higher apes. The formation of races attributed slightly to conditions of life or struggle for life, but mainly to sexual selection on the part of women. Traces the principle of sexual selection among animals.

The World of Life. By Alfred Russel Wallace. 408 pages. Illustrated. Chapman & Hall. 12s. 6d. net
A self-made summary of the life-work, in the realm of scientific thought, of one of the greatest of the pioneers of evolution, carrying on towards something like completion the work of Darwin. Wallace regards the age-long development of life as stages in the growth towards man, the crowning product of the process.

The Principles of Biology. By Herbert Spencer. 2 vols. Williams & Norgate .. .. 36s.
The aim of this work is to set forth the general truths of the study of life as illustrative of the laws of evolution; it also shows how a knowledge of these laws helps to illumine and interpret the facts of biology. In regard to the manner in which life evolved, Spencer holds to Darwin's theory of natural selection, but allows something to the inheritance of acquired character.

Outlines of Biology. By P. Chalmers Mitchell. 348 pages. Illustrated. Methuen .. .. 6s. net
This book is an invaluable manual for examination students. It has been specially revised by Dr. G. P. Mudge to meet the requirements of the conjoint examining board of the Royal Colleges of Physicians and Surgeons of England.

Development and Purpose. By Professor L. T. Hobhouse. Macmillan .. .. .. 10s. net
A memorable survey of the latest scientific researches, resulting in the conclusion that "a conditioned purpose constitutes the core of the world-process," and that there is a Mind of which the world-purpose is the object. The book builds up the scientific probability that the story of the universe is the orderly working out of a Divine thought.

Evolution and Man's Place in Nature. By Rev. H. Calderwood. 349 pages. Macmillan .. 10s. net
The main objects of this work are to trace the evidence of man's relation to the continuity of life on earth, and to describe the distinctive characteristics of human life.

The Biology of the Seasons. By J. Arthur Thomson. 384 pages. Illustrated. Melrose .. 10s. 6d. net
Intended for all who enjoy the pageant of the year and the drama of the seasons, and who see something of the evolutionary flow of things in the annual spectacle. The aim of the book is to get at the gist or inwardness of the yearly drama without going too minutely into the details of the successive scenes. Vivid, interesting, and thought-providing.

The Ascent of Man. By Henry Drummond. 444 pages. Hodder & Stoughton .. 3s. 6d. net
An application of the law of evolution to the growing refinement and elevation of mankind, first, through the unselfishness of maternity, and then through the love of others. A beautiful idea exquisitely worked out.

The Science of Life. By J. Arthur Thomson. 246 pages. Blackie .. .. 2s. 6d.
A short historical sketch of the evolution of the science of biology, especially in Darwinian and post-Darwinian days, showing how this science has, from insignificance, attained to a position which is central among the sciences, and of very great influence even upon the art of life itself.

Origin and Nature of Life. By Benjamin Moore. 256 pages. Williams & Norgate .. 1s. net
This book, by the Professor of Bio-Chemistry in the Liverpool University, traces, as thoroughly as modern knowledge allows, the relation of the phenomena of life with chemical and non-vital processes. "Life probably arose as a result of the operation of causes which may still be at work today, causing life to arise afresh."

Man's Place in Nature. By T. H. Huxley. Cheap editions.
With an introduction by Sir Oliver Lodge, this volume contains many other essays besides that which gives its title—*e.g.*, the relation of man to the lower animals; the present condition of organic nature; the educational value of the natural history sciences, etc.

Life and Matter. By Sir Oliver Lodge. 200 pages. Williams & Norgate .. 2s. 6d. net and 6d. net
"An exposition of part of the philosophy of science, with special references to the influence of Professor Haeckel." An able essay, antagonistic to materialism.

The Prolongation of Life. By E. Metchnikoff. 343 pages. Illustrated. Heinemann .. 6s. net
This work is a sequel to "The Nature of Man," by the same author, who believes that science may greatly prolong the lives of individuals, and thereby solve some difficult social questions. An extremely optimistic essay by a great experimentalist.

The Greatest Life. By Gerald Leighton. 275 pages. Duckworth .. .. 2s. 6d. net
A consideration of the theory of immunity, based on the accepted view that life involves adaptive change in response to environment. Dr. Leighton discusses immunity from the physical, mental, moral, and emotional standpoints. A man has, he suggests, certain natural and acquired tendencies, and according to these he is good or bad. On these lines, he holds, even spiritual phenomena are capable of explanation; and he maintains that if the future of man is to be in the direction of higher ethical progress, it must be by a scientific Christianity.

Psychology

The Human Mind. By James Sully. Two vols. Longmans .. .. 21s.
A textbook of psychology by a well-known authority, especially intended for those who desire a fairly full presentment of the latest results of research. Deals at some length with experimental psychology, and with illustrations of the principles on which the mind works in the abnormal conditions of insanity and hypnotism. A work of an advanced kind, but written in a clear, sound style.

Body and Mind. By William McDougall. 384 pages. Methuen .. .. 10s. 6d. net
The author describes his book as "a history and a defence of animism." A comprehensive survey of the problem of the relations between body and mind is given under the following form—(1) a history of the development of animism from the primitive idea of the ghost-soul to the present day; (2) a critical examination of alternative theories; (3) an attempt to state animism in a form compatible with sound epistemological principles, and with the established results of modern science.

The Principles of Psychology. By Herbert Spencer. Two vols. 1276 pages. Williams & Norgate. 36s.
One of the great classics of the study of the evolution of the feelings and intellect. In the first volume Spencer traces the parallel development of the nervous system, the emotions and intelligence. In the second volume he analyses the mental states of men, and deals with the metaphysical side of the problem of mind.

Physiological Psychology. By William McDougall. 172 pages. Dent .. .. 1s. net
A book of remarkable originality and insight, showing the interaction of physiology and psychology and the value of studying them in conjunction.

The Principles of Psychology. By William James. Two vols. Macmillan .. .. 25s. net
One of the great modern books that has profoundly influenced thinkers. The book contends that when psychology has ascertained the empirical correlation of the various sorts of thought or feeling with definite conditions of the brain it can go no further. If it goes further it becomes metaphysics. The author regards the laws of the co-existence of passing thoughts with brain-states as the ultimate laws of psychology. The book is "a mass of descriptive details running out into queries which only metaphysics can deal with."

The Expression of the Emotions in Man and Animals. By Charles Darwin. 392 pages. Illustrated. John Murray .. .. 2s. 6d. net
A study in the evolution of life from the psychological side. Emotion being more fundamental

than intellect, Darwin endeavours to find a connection between certain exhibitions of feelings in animals and certain instinctive expressions of emotions in man.

Psychology. By William McDougall. 251 pages. Williams & Norgate .. .. .. 1s. net
Mr. McDougall, Reader in Mental Philosophy at Oxford, has written also valuable essays on "Body and Mind" and on "Social Psychology." Regarding psychology as the "study of behaviour," he here attempts to answer the question: "What may we hope from psychology in the way of contributing to the welfare of mankind?" Suggestive and very modern.

Matter and Memory. By Henri Bergson. Allen & Unwin .. .. 10s. 6d. net
An essay, of great suggestiveness, on the relation between body and mind, wherein this limited question leads to all the greatest problems of metaphysics. Whatever may be thought of his peculiar conclusions, no one now doubts that Bergson stands quite apart from, and far above, all contemporary philosophers. His mind has the profundity of the Hebrew and the clarity of the Frenchman. And this book is so modern and sincere that many a beginner will find it easier to understand than the most elementary textbook of the subject.

Time and Free Will. By Henri Bergson. English translation. 252 pp. Allen & Unwin. 10s. 6d. net
This "essay on the immediate data of consciousness," by the eminent professor at the College of France, contains some of his most characteristic work. Especially it shows how lamentably in bondage we are, in all our thought, to analogies drawn from space and extension. Bergson asks here whether "the insurmountable difficulties presented by certain philosophical problems do not arise from our placing, side by side in space, phenomena which do not occupy space."

The New Psychology. By E. W. Scripture. 490 pages. Illustrated. Walter Scott .. .. 6s.
The new psychology is a purely mental science founded on experiment and exact measurement. Its apostles, as set forth in this book, are Fechner —of the Fechner-Weber law—Helmholtz, and Wundt. The writer admits that no physiological experiments or methods can ever reveal a mental act. Admitting that, we may go on to admit that the strength of voluntary action, the diminutions of fatigue, and so on, may be interestingly tested, as shown in this book; but the warrant for calling these valuable observations an introduction to a new science is not made out.

Formation of Vegetable Mould through the Action of Worms, with Observations on Their Habits. By Charles Darwin. John Murray .. 2s. 6d. net
The result of Darwin's keeping pots of earth with worms in them. He wished to learn how far a worm acted consciously, and how much mental power was displayed by animals so low in the scale.

Text-book of Psychology. By William James. 491 pages. Macmillan .. .. .. 7s. net
This is a condensation of the author's monumental "Principles of Psychology," so that it may be used for teaching purposes. Controversial questions discussed in the larger book are omitted, and some chapters for students are added.

Psychology: A Short Account of the Human Mind. By F. S. Granger. 235 pages. Methuen. 2s. 6d.
A successful attempt to simplify, in language and illustration, a subject that is inevitably abstruse. A useful introduction to the study of psychology.

Teachers' Handbook of Psychology. By James Sully. 625 pages. Longmans .. .. 6s. net
The writer of this book was at one time a teacher of psychology to teachers in one of the leading training colleges. Here he gives a general survey, revised up to date, and he includes a full bibliography.

An Introduction to Psychology, more especially for Teachers. By Thomas Loveday and J. A. Green. 272 pages. Clarendon Press .. .. 3s. 6d. net
A simple introduction to psychology, in which the Professor of Philosophy and the Professor of Education at Sheffield University have collaborated. The book is written for use by students in training colleges, and is wisely confined to the plainer elements of the subject, evading more advanced philosophical problems.

The Senses, Instincts, and Intelligence of Animals, with Special Reference to Insects. By Lord Avebury. 292 pages. Illustrated. Kegan Paul. 5s.
In this book Lord Avebury has collected his observations and experiments with regard to the senses and intelligence of animals, particularly insects, and has prefaced his work with such information about the organs of sense generally as is needed for an understanding of the observations. The experiments are of a miscellaneous character, but of great interest. Such topics as "How do insects find their way?" are discussed.

The Senses of Insects. By Auguste Forel. English translation by M. Yearsley. 324 pages. Illustrated. Methuen .. .. .. 10s. 6d. net
A remarkably study of the senses and psychology of insects, chiefly based upon ingenious experiments designed to explore insect senses which go beyond our own. A book from which large scientific generalisations have been made.

Memory and Its Cultivation. By F. W. Edridge-Green. 311 pages. Kegan Paul .. .. 5s.
A book in two parts, the first considering the faculties of the mind involved in memory, and the second discussing the improvement of memory so as to lighten labour. The author asserts that after discovering the facts which led him to write this book he could master a subject in about one-fifth of the time it previously took him.

The Interpretation of Dreams. By Professor Freud. George Allen & Unwin .. .. .. 15s. net
A study of the psychological technique by which dreams can be interpreted, and upon the application of which every dream may be introduced into an assignable place in the psychic activity of the waking state. The author endeavours to explain processes which give rise to the strangeness and obscurity of dreams, and to discover through them the nature of the psychic forces which operate to produce the dream.

The Man of Genius. By C. Lombroso. 370 pages. Illustrated. Maps. Walter Scott .. 3s. 6d.
A book that has had a European circulation and excited discussion in almost every language. The unrelieved pessimism of Lombroso reaches its deepest depths in this volume, which seeks to identify genius with degeneration. The author gathers his instances from a very wide field, but tinges them all with his peculiar hopelessness. The chief credit of Lombroso is that, in making men answer him, he makes them think.

Psychical Research. By Sir W. F. Barrett. 246 pages. Williams & Norgate .. .. 1s. net
This work, by a recent Professor of Physics in the Royal College of Science for Ireland, treats of unconscious muscular action, thought-reading, thought-

transference, hypnotism and suggestion, telepathy, phantasms of the living and dead, dreams and crystal-visions, spiritualism, survival after death, etc. A fascinating little book. Bibliography.

Human Personality, and its Survival of Bodily Death. By Frederic W. H. Myers. Abridged by his son. 470 pages. Longmans .. .. 10s. 6d. net
An admirable abridgement of one of the most remarkable books of recent times, which the author describes modestly as an "imperfect textbook to a branch of research whose novelty and strangeness call urgently for provisional systematisation." The evidences Myers accumulated were to him "signals glimmering out of night to tell man of his inmost nature and his endless fate."

Personality. By A. W. Momerie. 134 pages. Blackwood .. .. 3s.
This brief essay has had more influence in the history of thought than many great volumes. It is the brilliant reassertion of free will as against the materialists and determinists.

A Study of British Genius. By Havelock Ellis. 314 pages. Hurst & Blackett.. .. .. 7s. 6d.
The greater part of the book is devoted to the arrangement and collection of all available facts, the Dictionary of National Biography being the source of most of the materials. Concludes that the characteristics of men of genius are probably independent, to a large extent, of the particular field in which their ability is shown. Youngest and eldest children are generally the most gifted.

The Psychology of the Emotions. By T. Ribot. 455 pages. Walter Scott .. .. 6s.
Professor Ribot here continues the psychology studies which gained such a sensational prominence through the theories of William James and Lange. The book consists of two parts. The first studies the more general manifestions of feeling—pleasure and pain; the second deals with special emotions —fear, anger, sympathy, social and moral feeling, the æsthetic sentiment, and abnormal and morbid characters.

Apparitions and Thought-Transference. By F. Podmore. 401 pages. Illus. Walter Scott. 3s. 6d.
The author of this work is one of the enthusiasts who have founded the Society for Psychical Research, and here he aims at presenting, in a brief compass, a selection of the evidence upon which the hypothesis of thought-transference or telepathy is based. It does not lose but rather gains in weight by being an abridged edition of a larger book. It ranks with Mr. F. W. H. Myers's "Human Personality" as a book that must be read by all who would examine the evidence for a world of ghosts.

Animal Magnetism. By Alfred Binet and Charles Fère. 378 pages. Kegan Paul .. .. 5s.
An account of special researches into hypnotism and suggestion, undertaken chiefly at the famous French institution the Salpêtrière. Gives history of hypnotism from Mesmer, and describes ways of producing hypnosis and the symptoms of the hypnotic states. Has a chapter on hallucinations, and one on hypnotism and responsibility.

Alterations of Personality. By Alfred Binet. 365 pages. Chapman & Hall .. .. .. 6s.
Monsieur Binet brings together a storehouse of recorded facts on such fascinating themes as successive and co-existent personalities in the same life, and changes of personality by experiments in suggestion.

Hallucinations and Illusions. By E. Parish. 390 pages. Walter Scott .. .. .. 3s. 6d.
The International Congress of Sociology, meeting at Paris in 1899, originated an international census of waking hallucinations in the sane. The author of this book was engaged on that inquiry, with the result that he collected the information which is included in this volume, as a supplement to the results of the inquiry. An abstruse subject is treated with most industrious illustration.

Hypnotism and Suggestion. By Bernard Hollander. 300 pages. Pitman .. .. .. 6s. net
The result of thirty years' practical experience of hypnotism in daily life, education, and medical practice. Dr. Hollander considers two aspects of hypnotism—first, the value of the study of its psychic phenomena; and, second, its value as a therapeutic agent for the amelioration and cure of nervous and mental disorders. There are large numbers of recorded cases in recent experiments.

Illusions: A Psychological Study. By James Sully. 390 pages. Kegan Paul .. .. .. 5s.
A survey of the field of error, embracing not only the illusions of sense that may be included under a study of physiological optics, but also hallucinations, dreams, illusory introspection, and the deceits of memory and belief. A useful bibliography is included as an appendix.

Hypnotism. By Albert Moll. Walter Scott. 6s.
A thorough survey of "all that is most important in the whole province of hypnotism." Deals with the various theories of hypnotism, and describes original experiments. Medical and legal aspects of hypnotism are also considered, and there is a long chapter on occultism, a bibliography, and an excellent index of subjects and names.

Sanity and Insanity. By C. Mercier. 395 pages. Illustrated. Walter Scott .. .. .. 3s. 6d.
In this book the lecturer on insanity at the Westminster Hospital Medical School reviews almost the whole of his painful subject. It is an individual study, as many of the doctrines advanced admittedly are not accepted by the profession at large. The subject is made interesting both by completeness of knowledge and candour of expression.

Unsoundness of Mind. By Sir Thomas S. Clouston. 360 pages. Methuen .. .. .. 7s. 6d. net
Written rather for the general public than for experts. The book traces the mental history of a large number of families in the Orkneys, the writer contending that there should be more public knowledge of the conditions of mental aberration. An interesting and valuable work.

The Psychology of Insanity. By B. Hart. 176 pages. Cambridge University Press .. .. 1s. net
A work interesting not only to the medical man but also to the general reader, inasmuch as mental aberrations are in some degree present even in the sanest. The book is much influenced by the new and revolutionary ideas of Professor Freud of Vienna, who regards insanity not principally as a disease of the brain, but rather as arising from painful and disordered ideas. Bibliography.

How We Think. By John Dewey. Harrap 3s. 6d.
An elementary and practical study of psychology by the Professor of Philosophy in Columbia University. Has interesting side-tracks into logic, philology, and ethics.

Animal Behaviour. By C. Lloyd Morgan. 344 pages. Illustrated. Arnold .. .. .. 7s. 6d. net
The behaviour of animals implying intelligence, emotions, and unconscious instinct. Begins with the behaviour of cells, the behaviour of plants, and traces the development of consciousness in the individual intelligence and social actions.

The Evolution of Animal Intelligence. By S. J. Holmes. Bell .. .. 12s. net
This is an attempt, by a zoological expert of the University of Wisconsin, to trace animal intelligence back to its faintest beginnings in crustaceans and molluscs. Instinct arises earlier, according to the author. Intelligence is then traced onward, up to the mammals, which the author seems to think stop short of reasoning except in the case of men. An interesting and impartial book.

Researches on Irritability of Plants. By J. C. Bose. Longmans .. .. 7s. 6d. net
The author has found an automatic method of recording the response made by plants to excitation, without having recourse to the tedious method of photography. An account of a vast number of experiments is given, with a precision, detail, and wealth of illustration that prove the care and thoughtfulness of the experimenter and author.

Behaviour of the Lower Organisms. By H. S. Jennings. Macmillan .. .. 12s. 6d. net
The lower organisms experimented on as described in this book are chiefly one-celled organisms—amœba, bacteria, infusoria. The author tells of many attempts to stimulate them and induce reactions. He then passes on from behaviour that is perhaps mechanical to that which is psychic, springing, for example, from what seems an impulse of fear. The whole book is a fine example of modern experimental research.

Response in the Living and Non-Living. By J. C. Bose. Longmans .. .. .. 10s. 6d.
First the author explains "response" through the action of muscle; then studies electric and other forms of response, in plants, under varied conditions, such as temperature, prisms, and anæsthetics. Response is next studied in metals. Inorganic response is then carefully studied. A work of great experimental zeal and ability. The author is a professor in the Presidency College, Calcutta.

Philosophy

Aristotle. By Sir A. Grant. Blackwood.. 1s. net
An excellent sketch for the general reader of the life and work of the great Greek systematiser of knowledge, written by one who made his subject a life-study, and is admitted to be an authority on it, as well as an attractive popular expositor.

Aristotle and the Earlier Peripatetics. By E. Zeller. 1051 pages. Two vols. Longmans .. 24s.
A translation by B. F. C. Costelloe and J. H. Muirhead from Zeller's "Philosophy of the Greeks," and the most readily available general survey of Aristotle's works, with extended reproductions of the writings, and separate works on separate books.

Aristotle's Works. Translations by various writers.
Psychology. By W. A. Hammond. Allen. 10s. 6d
De Sensu and De Memoria. By G. R. T. Ross. Cambridge University Press .. .. 9s.
Nicomachean Ethics. By R. W. Browne. Bell. 5s.
The Organon. By O. F. Owen. Two vols. Bell. 5s.
Politics. By Benjamin Jowett. Clarendon Press. 3s. 6d.
Rhetoric. By J. E. C. Welldon. Macmillan. 7s. 6d.
Education. By John Burnet. Cambridge University Press .. .. 2s. 6d.

Plato and Platonism. By Walter Pater. 286 pages. Macmillan .. .. 7s. 6d. net
A scholarly presentation of Plato's doctrines, and sketch of his personality, for students of philosophy, by a writer who is as great a master of English as of Greek. A notable book, alike because of its subject and on its own account.

Plato. Translations by Benjamin Jowett. Clarendon Press
The best translations of Plato are by Jowett— the "Four Socratic Dialogues," 285 pages, costing 3s. 6d. net; and "The Republic," 610 pages, 12s. 6d., or in two volumes, 7s. net.

Critique of Pure Reason. By Immanuel Kant. English translation by J. M. D. Meiklejohn. 517 pages. Bell .. .. 3s. 6d.
This work contains in all essentials the philosophical teaching of Kant, usually known as "transcendentalism." The first part contains the analysis of knowledge, or the theory of experience, which Kant based upon the principle that space and time are qualities or conditions of our sensuous apprehensions, and that a statement in which conditions of time and space are introduced can never be held to be a truth about things in themselves.

The Philosophy of Kant. By Robert Adamson. 269 pages. Douglas .. .. 6s.
The writer is an enthusiastic disciple of Kant, who regards the Kantian philosophy as offering the only sound and fruitful basis for speculation, and, unlike his master, has the power of clear expression and popular exposition.

Kant's Critical Philosophy for English Readers. By J. P. Mahaffy and J. H. Bernard. Two vols. 658 pages. Macmillan .. .. .. 13s. 6d.
A translation of Kant—the "Kritik" and the "Prolegomena"—for advanced students who wish to really master the master. It contains an abundance of notes and much helpful information.

The Principles of Ethics. By Herbert Spencer. Two vols. Williams & Norgate .. .. 27s. 6d.
This work the author regarded as the crown of his system of thought. It aims at reducing morality to a science, and conduct is examined as it hinders or develops the welfare of the individual and the race. Spencer tries to show that self-sacrifice is a transitional and passing phase of morality, and that, as the evolution of society goes on, private welfare and public welfare tend largely to coincide.

Epitome of the Synthetic Philosophy of Herbert Spencer. By F. H. Collins. 692 pages. Williams & Norgate .. .. 5s. net
An excellent summary of Spencer's far-ranging theories and ideas, which was prepared under the authority of the great thinker. The work sets out from the idea of an unknowable First Cause behind everything, and deals with the field of actual knowable things—life, mind, sociology, and morality. It follows closely the arrangement of Spencer's works, and condenses his statements and arguments.

First Principles. By Herbert Spencer. 706 pages. Williams & Norgate. .. .. .. 2s. net
The chief work of the greatest of modern thinkers, and written in a somewhat easier style than the more specialised volumes of his philosophic system. It contains an explanation of all the fundamental ideas running through his other works, and is the best book for the student of Spencer to start on.

On Liberty. By John Stuart Mill. Longmans. 74 pages 1s. 4d
A philosophical examination of the rights of the individual in the State, and the degree of restriction that is just and necessary. The most carefully written and patiently thought out of all Mill's writings. The trend of events since Mill's day has been all in the direction of sinking individual claims in the wider claims of the State, a tendency which causes individualists to place a higher value on Mill's arguments, as being more and more needed.

The Ethics of John Stuart Mill. Edited by Charles Douglas. 359 pages. Blackwood .. 6s. net
The most usable edition of Mill's ethical writings, accompanied by such comments and introductions as will guide and stimulate the student. The editor holds that there is an inherent difficulty in reconciling individualism with an altruistic ethical theory, and that Mill's writings bring out the points.

Principles of Political Economy. By John Stuart Mill. 611 pages. Longmans .. .. 3s. 6d.
The book that is most generally accepted as the standard work on its subject. It builds on the foundations laid by Adam Smith, and in the main establishes what are now regarded as traditional beliefs, though its teachings are modified at various points by later students.

A System of Logic. By John Stuart Mill. 638 pages. Longmans .. .. 3s. 6d.
One of the most useful and permanent of the writings of Mill. For students rather than the general reader. Described by its author as "a connected view of the principles of evidence and of scientific investigation."

Essay on Human Understanding. By John Locke. Routledge .. .. 3s. 6d.
The masterpiece of John Locke, the English philosopher, who, before Herbert Spencer, had a greater influence on Continental thought than any other English writer. It denies the doctrine of innate ideas, and argues that knowledge must be a gradual growth based on experience. All ideas may be referred back to the senses, or to reflection by the mind on the materials gathered by the senses.

On Civil Government. By John Locke. 245 pages. Routledge .. .. 1s.
This edition includes Sir Robert Filmer's "Patriarchia," the book which led Locke to discuss the true bases of civil government, and define the political philosophy of the Whig Party.

Locke. By A. C. Fraser. Blackwood .. 1s. net
A good all-round study of a great English thinker, who has exercised an influence on European thought second to that of Aristotle. Locke wrote a plain, easy style, and his biographer is also very readable. He deals with the life, thought, and influence of Locke, marking his limitations as well as explaining his ideas and estimating his large, original contributions to the intellectual riches of mankind.

Francis Bacon: His Life and Philosophy. By John Nichol. Two vols. Blackwood .. 2s. net
A scholarly and popular exposition of Bacon's philosophy and work, with an extended sketch of his life, suitable both for the general reader and for the student who wishes to place Bacon properly in the sequence of thinkers.

Man and the Bible. By J. Allanson Picton. Williams & Norgate .. .. .. 6s. net
An exceedingly broad-minded review of the place of the Bible in human history. It attempts to separate between the natural power of the book over man's minds through its presentation of great self-evident truths, and the fetishism which accepts the Bible superstitiously.

Elements of Natural Philosophy. By Lord Kelvin and P. G. Tait. Cambridge University Press. 9s.
An investigation of laws in the material world, with the deduction of results. Gives a complete account of the subject in language adapted to the non-mathematical reader, and furnishes a connected outline of the intellectual processes by which the greater part of the knowledge has been extended into regions as yet unexplored by experiment.

A History of Intellectual Development in Europe. By John W. Draper. Two vols. Bell. .. 10s.
A bright survey by an American author, whose temperament led him towards sharp controversy.

History of European Morals. By W. E. H. Lecky. Popular editions. Longmans .. 2s. 6d. net
The period covered by Professor Lecky's survey is from Augustus to Charlemagne only. Everything Lecky wrote stimulates thought.

A History of Freedom of Thought. By J. B. Bury. 256 pages. Williams & Norgate. .. 1s. net
The story of the emancipation of reason, told, from the days of Greece till now, with remarkable lucidity and power, by the distinguished Regius Professor of Modern History, Cambridge.

History of the Rise and Influence of Rationalism. By W. E. H. Lecky. Longmans. .. 2s. 6d. net
A masterly sketch of the change of the world from a subservient acceptance of religious tradition towards freedom of thought and belief. "A remarkable contribution to the history of the human mind and human society."

History of War and Peace. By G. H. Perris. 256 pages. Williams & Norgate .. .. 1s. net
Traces, from the earliest to the latest times, "the path of man's progress from a state of war toward a state of peace."

Noncomformity, its Origin and Progress. By W. B. Selbie. 253 pages. Williams & Norgate. 1s. net
Starting with Wycliffe, Dr. Selbie traces Nonconformity down to modern Adult School Brotherhoods, and the warning voice of the Nonconformist conscience. Able and tolerant.

Political Thought in England from Bacon to Halifax. By C. P. Gooch.

Political Thought in England from Bentham to J. S. Mill. By Prof. W. L. Davidson.

Political Thought in England from Herbert Spencer to Today. By Ernest Barker.
Three volumes of the Home University Library (Williams & Norgate), 1s. net each volume, succinctly tracing the growth of government and the evolution of national and social consciousness.

The Map of Life. By William Edward Hartpole Lecky. 353 pages. Longmans .. 2s. 6d. net
A thoughtful book on conduct and character, discussing pleasantly questions of morals and happiness in life, and how both are affected by the rough-and-tumble of the world and by such things as money, marriage, and success.

The Childhood of Religions. By Edward Clodd. Kegan Paul.. .. .. 1s. 6d.
The early growth of religion traced, from Nature worship onward, and its development into a variety of faiths of different quality. A simple introduction to the study of comparative religion. Written in a fascinating style.

The Elements of Ethics. By J. H. Muirhead. 310 pages. John Murray .. .. 3s.
One of the clearest and most interesting of the books on ethics for the use of beginners, with the advantage of being quite up to date, and admirably co-ordinated with allied studies.

Ethics. By G. E. Moore. Williams & Norgate. 1s. net
As simple a discussion of the fundamental question of conduct as is possible in a brief and popular work. The main subjects under notice are utilitarianism, moral judgments, tests of right and wrong, free will, and intrinsic value. Mr. Moore has the power of giving an abstruse subject more tangibility than philosophers can usually suggest.

The Greek View of Life. By G. Lowes Dickinson. 248 pages. Methuen .. .. .. 2s. 6d. net
This work, by a Cambridge scholar, has gone through eight editions. It treats with great insight of the Greek views of religion, of the State, of the individual, and of art, with appropriate quotations from classic writers.

The Science and Philosophy of the Organism. By Hans Driesch. Two vols. Black .. 21s.
An abstruse and somewhat involved statement of a very interesting theory of life. The author regards the life-force as a self-governing thing that evolves according to its own laws and to the circumstances in which it is placed. Dr. Driesch goes back to Aristotle for his ideas of life, but interprets these ideas in the full light of modern research.

Man's Origin, Destiny, and Duty. By Hugh MacColl. Williams & Norgate .. 4s. 6d. net
An attempt to prove that the soul and the body are different entities; and the soul will survive the body by successive transformations, and will gradually develop upwards; that the psychic universe contains numberless ascending orders of intelligent beings above the human, though they are imperceptible to man's senses; and that the whole creation is maintained and directed by one infinitely powerful and intelligent being. The execution of the work is much less comprehensive than its aim.

The Psychology of Religion. By E. D. Starbuck. 423 pages. Diagrams. Walter Scott .. 6s
In a preface to this book, Professor William James the most eminent of American psychologists, describes it as bringing compromise and conciliation into the long-standing feud between science and religion, and he recommends it as affording matter for edification and improvement to Christians and scientists alike.

Conventional Lies of Our Civilisation. By Max Nordau. 346 pages. Heinemann .. .. 6s.
Tracing the causes of his dismal pessimism, the author finds them in having to live in the midst of institutions which he regards as false. Religion, monarchy, aristocracy, politics, economics, and marriage are alike treated as insincerities that afford evidence of race degeneracy. The reader is taken, groaning, through the very depths of despair.

The Duties of Man. By Joseph Mazzini. Cheap editions.
Mazzini in this book enforces the central idea of his political creed—that men go astray in making their rights the chief concern of their public lives. Having obtained liberty, they should initiate a constructive policy with duty as the watchword, and should not make gain their aim, but the building up of a worthier public and personal character.

The Social Contract. By Jean Jacques Rousseau. Allen & Unwin .. .. 1s. net and 2s. 6d.
The most accessible English edition of an epoch-making book, with a useful introduction and explanatory notes by the translator, H. J. Tozer. Rousseau argues in the book that government depends upon a social contract whereby the individual surrenders some of his individuality for assured protection by the State. Hobbes had advanced a similar argument, while Rousseau emphasises the State's obligations to the individual.

The Prince. By Machiavelli. Cheap editions.
A work of considerable political and historical interest, which has given to Machiavelli so sinister a reputation. The reader who remembers the period and country of the author will find that evil reputation undeserved.

Descartes: The Method, Meditations, and Selections from His Principles. By Professor J. Veitch. 473 pages. Blackwood .. .. .. 6s. 6d.
The best introduction to the thought of Descartes. Informative, explanatory, critical.

Henri Bergson. By H. Wildon Carr. 92 pages. Jack .. .. 6d.
This introductory sketch aims only at giving a general survey of the scope and method of the great French philosopher of today.

Berkeley. By A. C. Fraser. 242 pages. Portrait. Blackwood .. .. 1s. net
An admirable summary account, in Blackwood's Philosophical Classics, by Professor Fraser, of Berkeley, the man and his thought. The effects of the philosopher's writings are traced through later thinkers with enthusiastic appreciation.

The Great Illusion. By Norman Angell. 331 pages. Heinemann .. .. 2s. 6d. net
One of the most widely read books of the present day. A study of war between civilised nations from the economic aspect, showing that it must be uneconomic in its effects, and damage the victors more than it can advantage them.

Leviathan. By Thomas Hobbes. Routledge. 1s.
The book which underlies all modern discussions of the principles of public government. The State is depicted as Leviathan, and all-powerful. But Hobbes goes on to concentrate the powers of the State in the Sovereign who, as the representative of all, is endowed with supreme powers over public policy, civil and religious. The book led thinkers—notably Locke—to lay down the logical bases of civil liberty.

Fichte. By Robert Adamson. 222 pages. Blackwood .. .. 1s. net
A very able summary of the salient features of Fichte's philosophy, with an account of the philosopher. A difficult subject well handled.

Dictionary of Philosophy and Psychology. By J. M. Baldwin. 3 vols. Macmillan. 110s. net
The most complete general survey of the literature of man's study of the mind and of the subjects discussed in that literature. International in its scope and expression, and fully illustrated. A work of very high value, indispensable in any library of philosophy.

The Springs of Conduct. By C. Lloyd Morgan. 317 pages. Arnold .. .. 7s. 6d.
An essay in the evolution of ethics, by the well-known writer on animal intelligence. Extremely fresh and vigorous. All works on ethics are curiously remote from actuality, and this one is no exception to the rule, but it is far from being as bad as most.

The Nature of Man. By E. Metchnikoff. 309 pages. Illustrated. Heinemann .. .. 6s. net
This English translation of the "studies in optimistic philosophy," by the great Russian pathologist, is of great interest. The author describes first an extraordinary collection of "disharmonies in the nature of man"; then deals with religious and philosophical systems designed to diminish these; and, thirdly, with triumphant science.

Introduction to Science. By J. Arthur Thomson. 251 pages. Williams & Norgate .. 1s. net
Dr. Thomson, Professor of Natural History in Aberdeen, a profound and wide thinker, here deals with the scientific mood, the aim of science, scientific method, classification of the sciences, science and philosophy, science and art, science and religion, and the utility of science. A suggestive book.

The Grammar of Science. By Karl Pearson. Third edition. 394 pages. Black .. .. .. 6s. net
A revised and enlarged edition of a remarkable survey of modern knowledge. Intended as a criticism of the fundamental ideas of science, it has also a constructive aim. All the principal fields of thought and research are studied.

The Interpretation of Nature. By C. Lloyd Morgan. 164 pages. Arrowsmith .. .. .. 2s. net
Dr. Lloyd Morgan sets out to show that a belief in a divine purpose in the universe is not inconsistent with a whole-hearted acceptance of scientific ideas and methods.

Creative Evolution. By Henri Bergson. 425 pages. Macmillan .. .. 10s. net
The book that has been more discussed in the philosophical world than any other during the last few years. The translation is by Dr. Arthur Mitchell, of Harvard University, and Professor Bergson himself has revised the whole work carefully. His summary of his aim is that he first tries on evolutionary progress the two ready-made garments of mechanism and finality, and shows that neither fits. Next he reconstructs the main lines of evolution along which life has travelled by the side of that which has led to the human intellect. The intellect is thus brought back to its generating cause. Last, the writer tries to show how our understanding, by submitting to a certain discipline, can prepare a transcendental philosophy. This is the book on which the whole controversy respecting Bergson's philosophy is based.

Facts and Comments. By Herbert Spencer. 205 pages. Williams & Norgate .. .. .. 6s.
The last fruit from an old tree. Touches on many social subjects of present interest, and gives the great thinker's last thoughts on the ultimate questions of life.

Social Evolution

Origin of Civilisation. By Lord Avebury. 482 pages. Illustrated. Longmans .. 7s. 6d. net
Lord Avebury describes the social and mental conditions of savages, their art, marriage, family relations, religion, language, polity, and laws. Though the savages of today do not necessarily represent very accurately the condition of primitive man, the book is of great value to the student of social evolution.

The Dawn of Civilisation. By Sir G. Maspero. 800 pages. Illustrated. English translation by M. L. McClure. S.P.C.K. .. .. .. 21s. net
This great work, by a master of Egyptian science and of Oriental history and archæology, describes the ancient civilisations of Egypt and Chaldæa.

History of Civilisation. By Charles Seignobos. 3 vols. Fisher Unwin .. 2s. 6d. net per vol.
A wide survey of the history of ancient, mediæval, and contemporary civilisation — one volume devoted to each period. Popularly written, with valuable references for supplementary reading.

The Dawn of History. By J. L. Myres. 256 pages. Williams & Norgate .. .. .. 1s. net
The author of this work is Professor of Ancient History in Oxford University. He here traces in many parts of the world the story of those crises or generally abrupt changes through which nations emerge out of the unhistoric sameness of primitive life into the striving process of the "historic age," frequently through the efforts of some "great man."

History of Civilisation in England. By T. H. Buckle. Three vols. .. .. .. Cheap editions
A brilliant attempt to ascertain the laws and principles of human progress, and to trace their operation in English history. A stimulating work, but inaccurate in detail, and not generally accepted nowadays. The author contends that civilisation is largely affected by natural conditions.

Principles of Western Civilisation. By Benjamin Kidd. 518 pages. Macmillan .. .. 5s. net
Presents European civilisation as a developing system of life, with more organic unity than any of the nations or states included in it, and with a special meaning and purpose of its own. The purpose is to build up a better state of things in the immediate future; a projected efficiency that calls out the noblest energies of the race, and gives meaning to the self-sacrificing acts of the individual.

Extinct Civilisations of the West. By R. E. Anderson. 200 pages. Illustrated. Hodder & Stoughton 1s. net
A brief account of the traces of Norse colonies in Greenland and other parts of North America centuries before Columbus; of Welsh and Irish Celts who preceded even the Norsemen; of the Aztecs, their traditions, their hieroglyphics, their human sacrifices, religious services, their remarkable scientific knowledge, etc.; and of American archæology in general.

Extinct Civilisations of the East. By R. E. Anderson. 229 pp. Illus. Maps. Hodder & Stoughton 1s. net
A work on the origin and races of mankind: Chaldea and Babylonia; ancient Egypt; the Hittites, Phœnicians, and Hebrews; the Arab; and Iran, or ancient Persia. Interesting historical and ethnological chapters, valuable to the general reader, and to the student of Old Testament history.

The History of Mankind. By Friedrich Ratzel. Translated by A. J. Butler, with an introduction by E. B. Tylor. Three vols Illustrated. Macmillan .. .. 36s. net
A guidebook to the study of man and civilisation. To those beginning anthropological work it gives indispensable sketches of the races of mankind, especially of the barbaric peoples who display culture in its earlier stages. The illustrations number nearly twelve hundred. Popular in treatment and scientific in spirit.

The Childhood of Man. By Leo Frobenius. English translation by A. H. Keane. 504 pages. Illustrated. Seeley .. .. 16s. net
An admirable description of many aspects of primitive races, including personal adornment, tattooing, tests of manhood, origin of labour, dress language, sign and gesture language, etc.

The Child: A Study in the Evolution of Man. By Dr. Alexander Francis Chamberlain. 405 pages. Illustrated. Walter Scott .. .. .. 6s.
An extremely interesting book, tracing the most important phenomena of human beginnings in the individual and the race. The child is treated as a revealer of the past, and as indicating in its growth the progress of mankind. In making his investigations the author has covered a wide range of literature; indeed, the bibliography of books used fills thirty pages.

Ancient Types of Man. By Arthur Keith. 151 pages. Illustrated. Harpers .. .. 2s. 6d.
A clear and readable account of the types of mankind whose remains have been discovered at various depths in the earth. Professor Keith is an authority on the subject, and he has an original point of view on some problems of human origin.

Man Before Metals. By N. Joly. 365 pages. Illustrated. Kegan Paul .. .. 5s.
This brightly written book collects the proofs of the

great age of the human race, and in a second part treats of the customs, the industry, the moral and religious ideas of man as he existed before the use of metals was known.

Man and His Handiwork. By Rev. J. G. Wood. Illustrated. S.P.C.K. .. .. .. 5s. net
An interesting endeavour to trace out the history of the human race from the handiwork of man throughout the ages; the meaning of the weapons and utensils discovered by geologists, and their light on the life of the men who used them. There are about 500 pictures.

The Primitive Family in Its Origin and Development. By C. N. Starcke. 315 pages. Kegan Paul 5s.
Aims at ascertaining the nature of the primitive family, and points out the ideas on which it is based and the germ of moral growth it contains. Gives the theories of McLennan and Maine, and surveys the family arrangements of savages in all parts of the world.

Primitive Man. By E. Clodd. Illustrated. Hodder and Stoughton .. .. 1s. net
A concise popular introduction to the study of man in the Stone and Metal Ages, containing a bibliography. The primitive ideas of barbaric nations are quoted to illustrate the probable meanings of prehistoric remains, and the positions in which they are sometimes found.

Ancient Hunters and Their Modern Representatives. By W. J. Sollas. 416 pages. Illustrated. Macmillan .. .. 12s.
The clearest and fullest work on the study of the arts and conditions of the primitive inhabitants of Europe. Combines the most recent researches of French anthropologists and German geologists with the views of British students of the problems of prehistory. Shows that probably the ancestors of Tasmanian and African Bushmen dwelt in Europe in the warm intervals between the Great Ice Ages.

Anthropology. By Sir Edward Tylor. 463 pages. Illustrated. Macmillan .. .. .. 7s. 6d.
An admirable introduction to the study of primitive and savage man. A large and varied field of facts is surveyed in a clear, orderly manner by a leading authority, and the principal ideas are presented in an easy style, suitable for the general reader. A standard work.

Anthropology. By R. R. Marett. 256 pages. Williams & Norgate .. .. .. 1s. net
Mr. Marett is Reader in Social Anthropology in the University of Oxford, and an acknowledged authority on the customs and beliefs of primitive races. Anthropology, he says, studies man as he occurs at all times, and in all known parts of the world. It deals with such questions as race, language, environment, social organisation, law, religion, morality, especially in so far as individual traits reveal the universal.

Man and His Ancestor. By Charles Morris. Macmillan .. .. 5s. 6d. net
An effort to present the evolution of man in a popular manner by dwelling on facts discovered since the time of Darwin.

The Mind of Primitive Man. By Franz Boas. Macmillan .. .. 6s. 6d.
The chapters of this book are reprints of lectures delivered at the Lowell Institute, Boston. First the author tries to clear away racial prejudice, which he holds is insufficiently supported. He then discusses the influence of environment and of heredity, compares the mental traits of primitive and civilised man, and comes to the conclusion that culture is a phenomenon that depends on historical causes regardless of race. A thoughtful book, provocative of keen controversy.

Ethnology. By A. H. Keane. 425 pages. Illustrated. Cambridge University Press .. 10s. 6d.
Deals with the fundamental problems of the division of mankind into races, and then describes the primary racial groups. Written in a clear and interesting style by a master of anthropology.

Man: Past and Present. By A. H. Keane. Cambridge University Press .. .. .. 12s.
An exceedingly able survey of the chief racial divisions of mankind, and an examination of the changes since prehistoric times that have led to fresh ethnical groupings. The book is a complement of the author's work "Ethnology."

The Measurement of Social Phenomena. By Dr. A. L. Bowley. P. S. King .. .. 3s. 6d. net
This book deals with "the general problem of sociological statistics which defines or deliminates and enumerates classes, specifies attributes or characteristics of the members of those classes, measures these attributes and describes their variation, and discovers relations and casual connections." That is the publisher's own summary, but the book is not so dull as that summary suggests. It is a study of the measurement of progress by statistics.

Primitive Folk. By Elie Reclus. 336 pages. Illustrated. Walter Scott .. .. .. 3s. 6d.
Monsieur Reclus attempts to draw the ethnic individualities of a number of the more primitive races—races that are as children, with the intelligence of a child. He chooses his subjects from all climates between the extremest Polar regions and the equator. The book as a record of life is interesting, and still more as giving many forms of development of the mind of primitive man.

The Races of Man. By J. Deniker. 611 pages. Illustrated. Walter Scott .. .. .. 6s.
Gives the essential facts of the twin sciences of anthropology and ethnography. Designed for all those who desire to obtain a general notion of these sciences rapidly. The book brings into one volume a mass of valuable information gleaned from a great number of notes and memoirs in all languages.

The Human Species. By A. de Quatrefages. 498 pages. Kegan Paul .. .. 5s.
Discusses the unity of the races of man, the origin of mankind, the birthplace of primitive man, and the peopling of the earth. One part is given up to a description of fossil human races, which is now incomplete, owing to later discoveries. The last parts depict the physical and mental characteristics of existing races.

The World's Peoples. By A. H. Keane. 434 pages. Illustrated. Hutchinson .. .. 6s. net
A popular account of the bodily and mental characters, beliefs, traditions, and political and social institutions of the races of the world. Well illustrated by many photographs.

Prehistoric Peoples. By the Marquis de Nahaillac. 412 pages. Illustrated. Putnam .. 12s. 6d.
Claims to be an epitome of the manners and monuments of prehistoric peoples. Discusses the time and duration of the Stone Age; the life and habits of the people; their weapons and industries; the origin of fire, clothing, and ornaments; the beginnings of art and social organisations; the setting up of camps and fortifications; and the dawn of surgery.

Prehistoric Man. By W. L. H. Duckworth. 161 pages. Illus. Cambridge University Press. 1s. net
This book deals with the earliest phases in the history of mankind. It begins with the precursors of Palæolithic man, intermediate between mankind and the more highly developed apes, and follows on through the association of primitive man with animal remains, to the evolution of the higher human types.

Prehistoric Times. By Lord Avebury. 616 pages. Illustrated. Williams & Norgate .. 10s. 6d. net
This history of ancient man is derived from prehistoric remains found in various parts of the world, and from a study of the manners and customs of modern savages. The book is well illustrated with pictures of implements, works of art, and so on, from the prehistoric ages.

Prehistoric Europe. By James Geikie. 592 pages. Illustrated. Stanford .. .. .. 25s.
An outline of the chief physical changes on the Continent of Europe since the beginning of the Pleistocene period. The successive changes of climatical and geographical conditions are examined systematically.

The Stone Ages. By the Rev. Frederick Smith. 377 pages. Illustrated. Blackie .. .. 16s. net
An account of the flint implements found in North Britain and Ireland, with deductions of great interest and importance which the author has been able to draw concerning the nature of ancient man. There is considerable evidence of his having possessed heroic qualities and great ingenuity, and possibly also domestic qualities. An extremely interesting book.

Rough Stone Monuments and Their Builders. By T. Eric Peet. Illustrated. Harper. 2s. 6d. net
Written to enable those interested in Stonehenge and other great primitive monuments of Britain to learn something of similar buildings existing in different parts of the world. A summary of the latest researches on the subject, by one of the leading authorities of the younger generation.

The Ancient Stone Implements, Weapons, and Ornaments of Great Britain. By Sir John Evans. 747 pages. Illustrated. Longmans .. 10s. 6d. net
The standard work on the prehistoric instruments of the early inhabitants of Great Britain. A cautious and painstaking man of science, Sir John Evans has tried to reduce to order the various small objects of human manufacture found in the river gravels, caves, and haunts of the primitive Briton.

The Childhood of the World. By Edward Clodd. Macmillan .. .. 4s. 6d. net
An account of the thoughts and surroundings of the earliest men, when the greatest of all inventions—such as the uses of fire, the development of language, and the beginnings of writing—were coming into use. Written with great charm.

Remains of the Prehistoric Age in England. By Sir B. C. A. Windle. 312 pages. Illustrated. Methuen.. .. .. 7s 6d. net
An interesting and well-illustrated book by the President of Cork University College. It deals fully with stone, metal, and bone implements, burial-places, earthworks, pit-dwellings, and with the physical remains of prehistoric man.

Life in Early Britain. By Sir B. C. A. Windle. 244 pages. Nutt .. .. 3s. 6d.
An account of the early inhabitants of this island and the memorials which they have left behind them. Deals with Palæolithic and Neolithic man; the Bronze period; the Roman occupation of Britain; the Saxon occupation; tribal and village communities, etc.

The Making of Religion. By Andrew Lang. 316 pages. Longmans .. .. 5s. net
Deals with the supposed evolution of religious ideas which finds the origin of belief in a Supreme Being in the belief in ghosts. After considering the subject from many points of view, and examining primitive beliefs and various evolutionary theories, the author refuses to concur in this opinion as to the origin of religion, and summarises the primitive beliefs in support of his contention.

The Golden Bough. By Sir J. G. Frazer. Illustrated. Macmillan. Twelve vols.

Part 1.	Two vols.	20s. net.
Part 2.	One vol.	10s. net.
Part 3.	One vol.	10s. net.
Part 4.	Two vols.	20s. net.
Part 5.	Two vols.	20s. net.
Part 6.	One vol.	10s. net.
Part 7.	Two vols.	20s. net.

Vol. XII. General Index and Bibliography. 20s. net.

The most famous of all works on comparative religion, in any language, but, in the opinion of most students, somewhat too hypothetical. The book is, however, so charming that the reader does not very much care how far it is true; and no one will ever sift truth from error in this difficult subject. Facts from all times and places, the ancient and modern world, savages and civilised peoples, are here brought together to illustrate that inscrutable mystery of religion—the sacrifice. And they are delightful facts, too: the popular festivals of peasants in spring, midsummer, and harvest; the religion of woodmen and husbandmen and their cult of trees, and especially the "golden bough," and all kinds of sad, sweet, old pagan stories. The book has now developed into seven parts, published separately. (1) "The Magic Art and Evolution of Kings." (2) "Taboo, and the Perils of the Soul." (3) "The Dying God." (4) "Adonis, Attis, Osiris." (5) "The Spirits of the Corn and of the Wild." (6) "The Scapegoat." (7) "Balder the Beautiful."

Totemism and Exogamy. By Sir J. G. Frazer. Four vols. Macmillan .. .. 50s. net
This pioneer book on the obscure subject of totemism was prepared by Sir James Frazer for the "Encyclopædia Britannica," but only a part of it was included in that work. The materials accumulated upon the author so that he had to publish them in a separate treatise. The work deals with the religious, sexual, and social aspects of totemism.

The Mediterranean Race. By G. Sergi. 320 pages. Illustrated. Walter Scott .. .. .. 6s.
Only in recent years has the origin of the nations of Southern Europe been rescued from the idea that all white peoples are of Aryan blood. The view now is being generally accepted that the Mediterranean peoples had a separate origin, and this contention, put forward here by Signor Sergi, Professor of Anthropology in the University of Rome, has not only gained acceptance, but is being attested by the excavations in Crete and elsewhere. The case for the Mediterranean stock is here presented in a convincing manner.

The Origin of the Aryans. By Isaac Taylor. 339 pages. Illustrated. Walter Scott .. 3s. 6d.
Intended to be a summary of the labours of many scholars, and a digest of the literature that has grown up concerning the prehistoric ethnology and civilisation of Europe.

The Jews. By Maurice Fishberg. 578 pages. Illustrated. Walter Scott .. .. .. 6s.
An attempt to present the results of anthropological, pathological, psychological, and demographic investigation of the Jews. Based on careful scientific research in America and Europe. The book discusses the distribution of the Jews, their physical characters, types, customs, and occupations. There is a most useful bibliography.

Society and Politics

The Principles of Sociology. By Herbert Spencer. Three vols. Williams & Norgate.. .. £2 15s.
A work that founded a new science. In it Herbert Spencer brings all the affairs of society under the law of evolution, and shows that nations and states cannot be ready-made, but are gradually formed by a process of development. In spite of the length of the work, it is uncommonly readable, as it deals with matters of vivid interest and wide appeal.

The Study of Sociology. By Herbert Spencer. 423 pages. Williams & Norgate .. .. 10s. 6d.
A summary and at points a development of the larger work, "The Principles of Sociology." But it has a special value for all students of society, in that Spencer makes it a survey of all the main problems and difficulties connected with the new social science; and many of his remarks have not lost their force.

Social Evolution. By Benjamin Kidd. 385 pages. Macmillan .. .. 7s. 6d. net
The forces working in the evolution of society, on the whole, effecting the greatest good of the greatest number in a progressive community. But the greatest number is comprised of the members of generations yet unborn or unthought of, and to whose interests the existing individuals are usually quite indifferent. So the social forces work for future more than for existing generations.

Descriptive Sociology. By Herbert Spencer, David Duncan, Richard Scheppig, and James Collier. Eight vols. Williams & Norgate .. .. £7 15s.
An enormous collection of facts relating to the various races and nations of mankind, collected by a band of scholars under Herbert Spencer's direction, and arranged and classified by the famous thinker. The work aims to supply the student of social science with facts upon which to work.

Social Statics, and the Man versus the State. By Herbert Spencer. Williams & Norgate .. 10s.
In this volume Spencer unites some of his earliest and latest ideas. Published first in 1850, "Social Statics" is more brilliantly written than Spencer's other sociological works, but, although it contains the germs of many of the ideas of the synthetic philosophy, it also contains much that Spencer outgrew. The later work, "Man and the State," asserts the rights of the individual against the increasing regulative powers of Governments.

Social Psychology. By William McDougall. 389 pages. Methuen .. .. .. 5s. net
The author here traces the working of instinct in the social life of man. Instinct, he affirms, is a mental process, and involves knowing and feeling as well as doing. The principal instincts are examined, and their social results indicated. Self-consciousness, moral judgments, volition, imitation, play, and habit are defined, and their effects traced.

Heredity and Selection in Sociology. By G. C. Hill. 600 pages. Black .. .. .. 12s. 6d.
The author gives in the first place a concise exposition of the main facts of heredity and selection, based upon recent biological researches; and this part of the work has been revised by Professor J. A. Thomson, the eminent Scottish biologist. Mr. Hill regards the principle of selection as having the greatest importance in social life, and believes that conflict is necessary in order to secure selection.

Historical Sociology. By Frank Granger. 241 pages. Methuen .. .. 3s. 6d. net
This book deals with the bases of social problems; the primary relations upon which laws and politics have actually been built up; with the individual; the will of the people; genius and destiny; marriage; religion, and regeneration. It is an elementary treatise, and contains a bibliography.

The Spirit of Laws. By M. de Secondat, Baron de Montesquieu. Two vols. 816 pages. Bell. 7s.
This translation, by T. Nugent, is the only really adequate form in which one of the most influential books of the eighteenth century is accessible to English readers. Montesquieu was an ardent admirer of the constitutionalism developed in England, and helped to spread English ideals on the Continent.

The English Constitution. By Walter Bagehot. 292 pages. Kegan Paul .. .. .. 3s. 6d.
Describes the English Constitution as it stood in the years 1865 and 1866, since which date, as the author points out, there have been many changes in spirit and in detail. This fact hardly affects the value of the book, however; it merely carries on the process beyond its limits. The author discusses the Cabinet; the Monarchy; the House of Lords; the House of Commons; changes of Ministry, and their supposed checks and balances; the pre-requisites of Cabinet government, and the peculiar form which they have assumed in England.

English Political Institutions. By J. A. R. Marriott. 347 pages. Clarendon Press .. .. 4s. 6d.
The author, a lecturer and tutor in modern history and political science at Worcester College, Oxford, holds that history should be taught from the present time backwards, and so has written an introduction to English institutions, explaining the contemporary working of the constitutional machine; the executive, legislative, local government, judiciary, and the relations between the Mother Country and Empire. An excellent book, non-political, clear and comprehensive.

Parliament. By Sir Courtenay Ilbert. 256 pages. Williams & Norgate .. .. .. 1s. net
This excellent little book, by the Clerk to the House of Commons, gives a complete condensed account of the history, constitution, and practice of the English Parliament, and includes a comparison with the constitution and procedure of government in other countries. Contains a classified and critical bibliography of considerable value.

Housing. By Percy Alden and Edward E. Hayward. 168 pages. Headley .. .. .. 1s. net
This little book, by two well-known social reformers, gives a concise account of the history of housing legislation, and an excellent brief study of the chief issues of the problem. The authors warmly support the garden-city movement. The problems of London traffic are also discussed as bearing on the housing problem; and an excellent bibliography is included.

Public Health and Housing. By John F. J. Sykes. 216 pages. P. S. King .. .. .. 5s.
This book divides itself into three parts: the ascertained effects upon health of certain conditions of habitation; construction and misconstruction of

human dwellings; and usage and misusage. A thoughtful book, the outcome of wide experience on a serious problem.

History of Trade Unionism. By Sidney and Beatrice Webb. 558 pages. Longmans .. 7s. 6d. net
In describing the growth and development of the trade union movement, the authors give the political history of the English working class for nearly two hundred years. The trade union organisation of today is described in detail. The last chapter contains a realistic sketch of actual trade union life, by a trade union secretary. Bibliography.

Co-operation at Home and Abroad: A Description and Analysis. By C. R. Fay. King. 10s. 6d. net
A comprehensive examination of the co-operative movement as it has developed in the countries of Europe that are most advanced socially. The author shows how some phases of the movement are more suitable than others to national idiosyncracies.

The Co-operative Movement in Great Britain. By Mrs. Sidney Webb. 260 pp. Allen & Unwin. 2s. 6d.
A book written in the days when the author was Miss Beatrice Potter, but many times reprinted. It describes the origin and growth of the British co-operative movement towards industrial democracy, and introductory chapters give a general view of the condition of the working classes early in the nineteenth century.

Land Nationalisation. By Alfred Russel Wallace. 252 pages. Allen & Unwin .. 1s. and 2s. 6d.
A survey of the English land system, and a comparison of the system of landlord and tenant with that of occupying ownership. The effect of the influence of both systems on the welfare of the people is discussed, and land nationalisation is advocated.

Land Nationalisation. By Harold Cox. 238 pages. Methuen .. .. 3s. 6d. net
This little treatise, by an eminent individualist, is an argument against land nationalisation and land taxation, on the grounds—(1) of the ineffectiveness of such methods for the purposes desired; (2) of their injustice; (3) of difficulties in application.

The Adjustment of Wages. By W. J. Ashley. 362 pages. Longmans .. .. .. 12s. 6d. net
A study in the coal and iron industries of Great Britain and America. Gives a survey of existing conditions that help to a solution of the problem. Shows that Americans have something to learn from English conciliation boards, and Britishers something to learn from American "scales," as in machine-minding rates. Deals with the position of organised labour and capitalistic syndicates.

The Factory System. By R. W. Cooke-Taylor. 189 pages. Methuen .. .. 2s. 6d.
A handbook containing a popular statement of how the factory system came to be, and of the controversies which have been waged with regard to it, together with a summary of legislation concerning factories. Contains a list of official forms for use under the Factory and Workshop Acts.

The Effects of Machinery on Wages. By J. Shield Nicholson. 143 pp. Allen & Unwin. 1s. net.
The author wrote as Professor of Political Economy in Edinburgh University, and here discusses machinery in its various aspects in relation to labour—the substitution of machinery for labour; machinery as auxiliary to labour; its effect on the division of labour; its influence in bringing about the concentration of labour and capital, and its effect on the mobility of capital and labour. A book of arguments rather than facts.

Six Centuries of Work and Wages. By J. E. Thorold Rogers. 591 pages. Fisher Unwin. 10s. 6d. net
A master-work on English labour and social conditions, rural and urban, giving a comprehensive view of the whole situation as the author knew it.

Eight Chapters on the History of Work and Wages. By J. E. Thorold Rogers. Fisher Unwin. 2s. 6d. net
A valuable condensation, in a popular form, of the late Professor Rogers's "Six Centuries of Work and Wages," using the facts that have a bearing on present day life. The "Six Centuries" was itself an abridgement of Rogers's most enlightening and painstaking work, in eight volumes, entitled "A History of Agriculture and Prices in England." A mine of information for those who regard history from economic and social standpoints.

Evolution of Modern Capitalism. By J. A. Hobson. 450 pages. Walter Scott .. .. .. 6s.
In this work Mr. Hobson traces the origin of modern capitalism; the instrument by which it works machinery; the structure of industry before machinery; the development of machine industry; the structure of modern business, trades, and markets; combinations of capital; industrial depression; the demand for labour, and the quality of labour; the economy of high wages; and the effects of modern industry on workers as consumers. A clear and well-balanced statement.

Capital. By Karl Marx. English translation by S. Moore and E. Aveling. Glaisher. 10s. 6d.
One of the most famous of all works on economic science, and the basis of many socialist arguments. It consists of a comprehensive critical analysis of capitalist protection and its effects, with a dramatic picture of the irresistible march of capitalism.

Sweating. By Edward Cadbury and George Shann. 145 pages. Headley Brothers .. .. 1s. net
The writers give, in brief yet systematic form, the facts and theories of sweated industries. As they intend the book primarily for working men, they have avoided the use of technical terms. Sweating as practised in the past and as understood at present is defined. The economic cost of it is set forth, causes are traced, and remedies are drafted.

Sweated Industry. By Clementina Black. 281 pages. Duckworth .. .. 2s. net
"Sweating" is applied in this book to any method of work under which the workers are extremely ill paid or extremely overworked. Miss Clementina Black has a remarkable knowledge of the subject, and brings together startling facts respecting "the poorest of all," workers in factories, shop-assistants, clerks, waitresses, traffic workers, and wage-earning children. She also discusses at length the question of a minimum wage.

Money and Its Relation to Prices. By L. L. Price. 200 pages. Allen & Unwin .. .. 1s. net
An inquiry into the causes, measurement, and effects of changes in general prices, with a consideration of the economic effects of these changes, the rise of prices consequent on the discovery of America and other "realms of gold."

Things that Matter. By Sir Leo Chiozza Money, M.P. 299 pages. Methuen .. .. .. 5s. net
A collection of essays on social and economic questions, by a writer of authority with a clear style and an original mind. The aim of the book is to direct attention to the problems and dangers which demand the grave attention of the nation. Deals with wages and industry, prices and the cost of living, education and insurance, emigration and foreign investments.

Riches and Poverty. By Sir Leo Chiozza Money, M.P. 349 pages. Methuen .. .. 5s. net
A scathing indictment of the unequal and unjust distribution of wealth in the British Isles, full of dreadful facts, and offering proposals which, after all, appear inadequate to the evil situation.

Lombard Street. By Walter Bagehot. 359 pages. Smith, Elder .. .. 3s. 6d. net
An account of the money-market and its relations to constitutional and commercial affairs. The money-market, Bagehot affirms, is no impalpable abstraction, but a concrete reality, and must be discussed as such. Banking in commerce, and its basal position in all enterprise, distinguishes modern methods from all previous methods.

Cash and Credit. By D. A. Barker. 143 pages. Illustrated. Cambridge University Press. 1s. net
The writer describes his book as an attempt to give a sketch of the theory of money in its most practical aspect, so as to provide a stepping-stone to more detailed study. He describes cash and credit from the point of view of the counter of a country bank.

Money and the Mechanism of Exchange. By W. Stanley Jevons. 349 pages. Kegan Paul .. 5s.
A descriptive essay on the ancient and modern monetary systems of the world, and the method in which the use of money is immensely economised by the cheque and clearing system now being developed and perfected. Explains the functions of money, the mechanism of exchange, promissory notes, and the means of regulating a paper currency.

For and Against Experiments on Animals. By Stephen Paget. With an Introduction by Lord Cromer. Nisbet .. .. .. 4s. 6d.
Gives a clear account of the chief results obtained during the past thirty years, by the help of experiments on animals, stated, as far as possible, in the very words of the men who did the work. Considers the anti-vivisection evidence, describes the anæsthetics used on animals, and cites the report of inspectors and the report of the Royal Commission.

The Socialist Movement. By J. Ramsay MacDonald. 256 pages. Williams & Norgate .. 1s. net
In this book Mr. Ramsay MacDonald, the recent leader of the Labour Party in the House of Commons, sets out to state clearly and authoritatively what Socialism means, and what its purpose is, and to distinguish it from the many irrelevant theories with which it is often credited. The book contains a valuable classified bibliography.

The Crown of Wild Olive. By John Ruskin. Allen & Unwin .. .. 1s. net
A reprint of lectures pointing out the weaknesses and insincerities of modern society, and developing Ruskin's peculiar tenets of socialistic co-operation and conscience. One of the most simple and eloquent of his books, but with a remarkably ornate introduction, designed, apparently, to influence the conduct of men by sheer oratorical power.

Time and Tide. By John Ruskin. Allen & Unwin .. .. 1s. net.
Elaborating Ruskin's ideas of the place of labour in the world and the responsibilities of riches. Ranking in simplicity and directness of treatment with "The Crown of Wild Olive."

PRICES OF BOOKS

In all cases the prices in this list are the maximum prices, and in many cases, whether indicated or not, there may be a discount of threepence in the shilling. Almost invariably shilling books, and nearly all technical works, are net.

Unto This Last. By John Ruskin. Allen & Unwin .. .. 1s. net
Four essays on political economy and social organisation contributed to the "Cornhill Magazine," but brought to an end because they were "reprobated in the most violent manner" by the readers.

Progress and Poverty. By Henry George. Kegan Paul .. .. 1s.
An exposition of the single-tax theory on land, for the relief of industry. The author would tax land up to its full economic value, apart from improvement. The book is not an exposition of Socialism, as is generally supposed, but a proposal for a new form of taxation, consistent with individualism.

The Commerce of Nations. By C. F. Bastable. 226 pages. Methuen .. .. 2s. 6d.
Men of the present generation have in many cases forgotten, or never knew, the history of the freeing of trade from hampering restrictions. The writer shows how modern Protectionism has grown and flourished on ideas inimical to true progress.

Land and Labour: Lessons from Belgium. By B. Seebohm Rowntree. .. .. Macmillan. 5s. net
The author has set himself the task of investigating the connection between social conditions and the methods of holding land in various countries, but for the present concentrates on Belgium. There he has studied the main aspects of social and economic life for four years, with the result that the land system is described in detail—industrial questions, with the wages paid, are considered; agriculture is treated at considerable length, with transport facilities, taxation and education; and, further, such subjects as the standard of living, housing, destitution, and unemployment are discussed. An admirable book, full of information.

A History of Factory Legislation. By B. L. Hutchins and A. Harrison. 298 pages. P. S. King .. 6s.
This very useful general sketch of the story of factory legislation, from the days of the Poor Law of Elizabeth to 1910, has deserved and achieved considerable popularity. To the latest edition Mr. Sidney Webb contributes a preface, and briefly retells the story. The coming of the factory system is a phenomenon which every citizen should understand. This book provides the materials.

An Introduction to English Economic History and Theory. By W. J. Ashley. 2 vols. Longmans .. .. 15s. 6d.
Deals with the village community, the merchant and craft guilds, the supremacy of the towns, the agrarian revolution, and the Tudor enclosures. Covers the period from the Norman Conquest to the sixteenth century. An admirable work, introducing the general reader to the study of great natural forces, often neglected in ordinary historical books.

Principles of Political Economy and Taxation. By David Ricardo. Dent .. .. 1s. net
Ricardo, whose work was suggested by "The Wealth of Nations" of Adam Smith, was one of the greatest exponents of the old, orthodox political economy.

The Subjection of Women. By John Stuart Mill. 128 pages. Longmans .. .. .. 6d. net
The first formal examination of the relations between men and women in public life, leading up to the theory that absolute equality should exist in all civic and national respects. While the abstract argument remains the same, the illustrative circumstances of disparity between the sexes—particularly in legal respects—has been considerably varied in favour of women since the book was written.

Political Economy. By S. J. Chapman. 253 pages. Williams & Norgate .. .. .. 1s. net
The beginner could not consult a better introduction to the science of economics. Though thoroughly scientific, it is free from technicalities. There is a small bibliography.

The Wealth of Nations. By Adam Smith. Cheap editions .. ..
The book on which the modern science of political economy is based, though some of Smith's views have been effectually controverted. The book overthrew entirely the mercantile system which supposed that nations could enrich themselves by shutting off foreign trade and hoarding gold. It proved that wealth came by the interchange of the products each country could most suitably bring into the world's general market.

The Science of Wealth. By J. A. Hobson. 256 pages. Williams & Norgate .. .. 1s. net
Mr. Hobson, a prolific writer on concrete social and economic questions, here studies "the structure and working of the modern business world in which wealth is made and distributed as income." The work is in close touch with actual conditions.

Industrial Democracy. By Sidney and Beatrice Webb. 929 pages. Longmans .. .. 12s. net
Contains a mass of facts on the labour question in all its aspects, gathered by the authors from personal investigations. The organisation and importance of the labour movement are admirably described.

Life and Labour of the People of London. By the Rt. Hon. Charles Booth. 17 vols. Macmillan. .. ..5s. net per vol.
An important investigation of the conditions of life and labour in London, issued during the years 1892 to 1903. Mr. Booth was assisted by many devoted workers, and the whole area was examined with astonishing minuteness. In this work appeared first an economic classification of the population which has since been used by Mr. Rowntree and others—viz., class A, lowest class; B, irregular work; C, intermittent earnings; D, small regular earnings; E, standard earnings, the latter including artisans of all kinds; F, best paid artisans and foremen; G, lower middle, including small shopkeepers and clerks; and H, including those who keep servants. It was found that about 30 per cent. of the population were in poverty (classes A-D), and about 70 per cent. in comfort (classes E-H).

The Psychic Factors of Civilisation. By Lester F. Ward. 369 pages. Ginn .. .. 8s. 6d. net
An evolutionary tracing of the age-long advance in psychic processes to a culmination in social action, in which society will attain a collective consciousness, find its soul, and establish sociocracy as a form of government.

Garden Cities of Tomorrow. By Ebenezer Howard. 167 pages. Illustrated. Allen & Unwin. 1s. net
An interesting and inspiring little book, by the founder of the garden city movement. Shows how the attraction of the town and the attractions of the country may be combined to avoid the defects of urban and rural life.

Utopia. By Sir Thomas More. Cheap editions.
A picture of an ideal Commonwealth, in which every citizen contributes to the general store of the community according to his ability, and receives from the State according to his wants. Money is abolished, and wealth consists entirely of things. The intellectual, moral, and religious features of the State, as well as material conditions, are described.

Rural England. By H. Rider Haggard. Two vols. Longmans .. .. 12s. net
An account of agricultural and social researches carried out in 1901 and 1902. A most valuable document on the condition of the country-side, full of facts bearing on the chief problem of modern English life. Here is an arsenal of facts for all interested in the resurrection of British peasantry.

Life in an English Village. By Maud F. Davies. 319 pages. Fisher Unwin .. .. 10s. 6d. net
An account of the conditions of life in a typical small parish in Wiltshire. The social, economic, and moral aspects are dealt with, and the causes of poverty examined. The book also contains a sketch of the history of the village. A most interesting work for social students.

The English Village Community. By Frederic Seebohm. 453 pages. Illus. Longmans. 4s. 6d. net
A historical survey of the old land systems of England, showing the prevalence of the open-field system throughout Great Britain in the Middle Ages, and describing the manorial system, the tribal system, and various local systems; also tracing the development of serfdom out of the manorial system. A valuable book for the student of social life.

Rural Rides. By William Cobbett. Dent. 1s. net
Mr. Chesterton's estimate of Cobbett is that he was the last representative of that real democracy which was a return to Nature, and which only poets and mobs can understand. Few have loved the English country and the poor with the real, sturdy downrightness with which Cobbett loved them, and few, if any, have described English country scenes with the vigour and freshness and the profound simplicity with which he described them.

Fields, Factories, and Workshops. By Prince Kropotkin. 477 pages. Nelson .. 1s. net
Discusses the advantages which civilised societies could derive from a combination of industrial pursuits with intensive agriculture, and of brain work with manual work. The decentralisation of industries, together with the development of agriculture, is put forward as the most hopeful path to social progress. Perhaps an over-optimistic point of view.

Evolution of Industry. By D. H. Macgregor. 252 pages. Williams & Norgate .. .. 1s. net
This book, by the Professor of Political Economy at Leeds, deals with the recent changes which have given us the present condition of the working classes. It deals admirably with "labour unrest," and with the relation of the people to the land.

New Atlantis. By Francis Bacon. Cheap editions.
This sketch of an Utopian commonwealth, imitated from More's "Utopia," was written in Latin, and was published after Bacon's death. The New Atlantis is, in position, a forecast of Australia; and the book is a glorification of science in improving the condition of mankind.

The State. By Woodrow Wilson. With introduction by Oscar Browning, M.A. Harrap. 7s. 6d.
A study of the elements of historical and practical politics, by the man who presides over the American people. The work is worthy of a great scholar and statesman, and is interesting to all nationalities.

The City of the Sun. By Thomas Campanella. 46 pages. Routledge .. .. 1s.
In this Italian outline of a fanciful State, the place is pictured as being "immediately under the equator," but where is not indicated. The writing is largely symbolical or allegorical, and has not the air of reality of More's "Utopia."

The Condition of England. By C. F. G. Masterman. 225 pages. Methuen .. .. .. 1s. net
An extremely interesting study of the people of England at the present day. Gives a most convincing picture of the real inner life of the various classes: the wealthy; the middle classes; the artisans; the very poor. A book to be read by all social students. Points out the real direction in which hope lies for the future.

Looking Backward. By Edward Bellamy. Cheap editions.
A story of an ideal future social State, in America, into which a hypnotised sleeper wakes when Capital and Labour have settled their accounts, and have come to an agreement that gives everybody the work and reward suitable for him. This communistic city looks back on our age of competition and warring interests as on days of savagery.

The Nemesis of Nations. By W. Romaine Paterson. 348 pages. Dent .. .. .. 10s. 6d. net
The author holds that slavery was the foundation of ancient states, and his book deals with the law of slavery as the first law of nations, namely, "that masters have the power of life and death over slaves, and whatever the slave earns he earns for his master."

The Greek Commonwealth. By Alfred E. Zimmern. 452 pages. Clarendon Press .. .. 8s. 6d. net
An attempt to show clearly what Athens was really like in the fifth century before Christ. With full knowledge and keen insight the author discusses the elements of citizenship as understood in ancient Greece, the economics of town and country, and the problems introduced by extending enterprise and power. A scholarly, thoughtful, sympathetic book.

Betting and Gambling: A National Evil. By B. S. Rowntree. 262 pages. Macmillan .. .. 6d.
This valuable, informational book is written by a number of well-known publicists, such as Mr. J. A. Hobson, Mr. Ramsay MacDonald, and Canon Horsley, as well as by Mr. Seebohm Rowntree, the editor. It shows the extent of gambling, and exposes its moral weakness.

The Criminal. By Havelock Ellis. 357 pages. Illustrated. Walter Scott .. .. .. 6s.
A critical summary of the results of the science now known as criminal anthropology, or the study of the criminal as he is in himself, and as he becomes in contact with society. The author has brought together a large amount of evidence which has been collected in regard to the physical and psychical characteristics of criminals. The author deals with the treatment of criminals, and shows that intellectual education is of no value; physical and moral education, and such training as will enable a person to play a part in social life, are needed.

Crime and Insanity. By C. A. Mercier. 254 pages. Williams & Norgate .. .. .. 1s. net
The well-known physician in mental diseases attempts here to discover, from the biological standpoint, what crime actually is, and to study it in relation to insanity. Dr. Mercier's view of insanity is of great interest, as he distinguishes it altogether from *mental* disorder. He regards it as disorder of *conduct*.

PRICES OF BOOKS

In all cases the prices in this list are the maximum prices, and in many cases, whether indicated or not, there may be a discount of threepence in the shilling. Almost invariably shilling books, and nearly all technical works, are net.

Crime: Its Causes and Remedies. By Cesare Lombroso. 471 pages. Heinemann. .. 16s. net
A translation, under an American committee, of the French version of an Italian classic. The author describes his work as "the outlines of a system of criminal therapeutics." It discusses the chief social causes of crime. The born criminal is held to be a distinct anthropological type, and is treated as a moral imbecile. Various existing methods of the public control of criminals are reviewed. The book is based too exclusively on Italian types, but has had a great effect on penalogy.

Science and the Criminal. By C. Ainsworth Mitchell. 250 pages. Illustrated. Pitman. .. 6s. net
This description of the various methods used by experts in the detection of crime is better reading than any detective story. Among other subjects, the book deals with methods of capture, personal identification, anthropometry, handwriting, the clues which may be found in inks and papers, and gives the history of several sensational trials.

Physics and Politics. By Walter Bagehot. 224 pages. Kegan Paul .. .. 5s.
A brilliant attempt to apply some principles of modern biology to the study of political society. Suggests that imitation, unconscious as well as conscious, is a great social force. Discusses the use of conflict in the making of nations and the development of culture. Shows that slight causes may change a people from the stationary to the progressive state of civilisation, or the converse.

The Village Labourer. By J. L. Hammond and B. Hammond. Longmans .. .. .. 9s. net
This book is a study of the English labourer during the worst period of his long story—that is, between 1760 and 1832—when he was losing almost entirely his hold on the land, and was becoming a threatened man on a slippery slope.

International Problems and Hague Conferences. By J. T. Lawrence. Dent .. .. 3s. 6d. net
A useful general sketch of the need for international laws, and the part played in suggesting such laws by The Hague Conference. The writer foresaw many of the dangers which have become manifest since the greater part of the world went to war. The book is useful in setting up a standard of conduct respecting which the reader can judge who has observed and who has disregarded it.

Social Worker's Guide. By J. O. Haldane. Pitman .. .. 3s. 6d. net
An invaluable dictionary of all kinds of agencies for ameliorative social work. The contributors, more than fifty in number, are all deeply engaged in such work. The aim is to give information rather than to offer opinions.

Poverty and Waste. By Hartley Withers. Smith, Elder .. .. 3s. 6d. net
A very sensible examination of waste as one of the causes of poverty. The writer shows clearly the enormity of the waste arising from our want of organisation. One case he instances with telling effect is expenditure on advertising. A thoughtful book for the average citizen.

Temperance Progress of the Nineteenth Century. By J. G. Woolley and W. E. Johnson. Chambers. 5s.
It is significant that a large part of this book deals with temperance work in the United States and the British colonies, where temperance reform has had far greater influence than in Great Britain. There is a terrible chapter on "Civilisation as the Apostle of Vice"—through drink. An impressive book.

Child Labour in the United Kingdom. By Frederic Keeling. P. S. King .. .. .. 7s. 6d.
This study of the development and administration of the law relating to the employment of children was prepared on behalf of the British section of the International Association for Labour Legislation. It outlines the history of child labour legislation, summarises regulations adopted in administration, recommends reforms, and gives invaluable tables of statistics which should be within the reach of all who are interested in the subject.

Education

Education : Intellectual, Moral, and Physical. By Herbert Spencer. Williams & Norgate.. 1s. net
Perhaps the mostly widely read book on education ever written, and one of the most suggestive. It overturns once for all the inherited idea of a purely bookish and literary education, and shows how wide is the true educational ideal. Readers of Spencer's Autobiography will see how largely his comments on education spring from his own experience.

The Montessori Method. By Maria Montessori. Translated from Italian. Heinemann. 7s. 6d. net.
An exposition of a system for teaching very young children, or children of defective intellect, through the senses, developed after long study by an Italian lady who is a doctor and psychologist. The system has proved very successful in schools for backward children, and has attracted attention throughout the whole educational world.

Emile ; or, Education. By J. J. Rousseau. Cheap editions.
A work which had an enormous effect on European thought and social life, as well as on education.

Froebel's Chief Writings. Arnold .. 4s. 6d. net
An excellent condensation and translation of the writings of Froebel, by Dr. Fletcher of Cambridge and Professor Welton of Leeds. The translators have kept their heads, and see the faults as well as the good points of their idealistic subject.

Froebel and Education by Self-Activity. By H. C. Bowen. Heinemann .. .. .. 5s.
A careful presentation of the essential principles of Froebel's system of teaching young children.

The Early Education of Children. By Laura L. Plaisted. 398 pages. Illustrated. Clarendon Press .. .. 4s. 6d. net
A very practical manual of teaching for infant schools, with an excellent admixture of theory and method. Dr. Ormerod, the School Medical Officer for Oxford, contributes a very useful chapter as an appendix on the medical responsibilities of the school-teacher in early detection of common diseases, attention to small injuries, and to habits that promote health.

The Educational Ideal. By J. P. Munroe. 270 pages. Heath .. .. 3s. 6d.
A historical study of the development of the educational ideal in modern times, dealing with Rabelais, Bacon, Montaigne, Locke, Rousseau, Pestalozzi, Froebel, etc. A sound book.

The Making of Citizens. By R. E. Hughes. 405 pages. Walter Scott .. .. 6s.
A well-considered and interesting informational survey of the primary and secondary school systems of England, Germany, France, and the United States, with chapters on the education of girls and of defective children. Mr. Hughes wisely shows that each system can only be understood in its own setting, as an expression of national idiosyncrasies.

Education as a Science. By Alexander Bain. 453 pages. Kegan Paul .. .. .. 5s.
A survey of the teaching art from a scientific point of view. The fruits of ordinary experience are tested and amended and brought under the ascertained laws of the mind. One part is devoted to the bearing of the intellect and emotions on education, and the place of the various sciences in the training of the mental faculties is considered. A brilliant attempt to reform the methods of education in the light of modern psychology.

Education ; Areopagitica ; The Commonwealth. By John Milton. 292 pages. Harrap. 2s. 6d.
A reprint of three statesmanlike works by the great Puritan poet, containing also biography, introduction, and notes. The "Areopagitica," especially, which is the charter of the freedom of the Press, should be in the hands of every young man and woman.

The Great Didactic. By John A. Comenius. Black .. .. 7s. 6d.
The fullest translation of the first great book of educational methods published after classical times.

Ambidexterity. By John Jackson. With an introduction by Major-Gen. Sir R. S. S. Baden-Powell. 258 pages. Illustrated. Kegan Paul. 6s. net
An argument for the natural development and rational training of both hands, and its effect upon the development of both parts of the brain. Deals both with the scientific and practical views of the matter, and gives a list of trades and sports in which ambidexterity is a gain.

The Romance of the Oxford Colleges. By Francis Gribble. Mills & Boon.. .. .. 2s. 6d. net
The author holds rightly that the average person is most interested in the stories of human interest that gather round the grey quadrangles of Oxford, and he tells such stories in connection with all the colleges very brightly.

The Romance of the Cambridge Colleges. By Francis Gribble. Mills & Boon .. .. 6s.
The author—who, by the way, is an Oxford man—seeks "to recall interesting careers of all kinds, and to revive the memories of those events which have brought one college after another into intimate relation with the life and thought of England as a whole." Executed with vivacity and grace.

Educational Writings by Locke. Arnold. 4s. 6d. net
An attractive reprint of the works of lasting value of John Locke, relating to education, edited by Professor J. W. Adamson of London University. Essential work well done.

Progress of Education in the 19th Century. By J. L. Hughes and L. R. Klemm. Chambers. 5s. net.
A very able and broad survey, both as regards subjects and countries. The salient features of educational advance are noted almost wherever they may be observed. The only omission is Japan, which might have furnished matter of great interest.

The Schools of Medieval England. By A. F. Leach. Methuen .. .. 7s. 6d. net
A most careful and scholarly history of the schools of England before the accession of Edward VI. No other history covers anything like the same historical ground. Over forty illustrations.

Pestalozzi : His Life and Work. By Roger de Guimps. 448 pp. George Allen & Unwin .. 6s.
The standard book on Pestalozzi. It has an introduction by R. H. Quick.

Eugenics

Essays in Eugenics. By Sir Francis Galton. Eugenics Education Society .. .. 1s. 6d. net
A collection of essays to neutralise misrepresentations of eugenics by writers who misapprehend its purpose. It contains several lectures and papers by its author that are unobtainable in any other form. The author explains clearly what Eugenists do and what they do not seek to attain.

Parenthood and Race Culture : an Outline of Eugenics. By C. W. Saleeby. Cassell. 7s. 6d. net
An attempt to survey and define the whole field of the new science of improving the race of human beings. Shows that eugenics is at once a science and a religion, based upon the laws of life, and recognising in them the foundation of society. Dr. Saleeby has done more than any other living man to popularise eugenics in this country, and he wears the mantle of Sir Francis Galton.

The Feeble-Minded. By E. B. Sherlock. 347 pages. Illustrated. Macmillan .. .. 8s. 6d. net
A guide to study and practice. Deals with the large class of human beings who do not appear to have attained the average mental level. Earlier chapters are concerned with psychological and physical traits that are believed to be connected with mental happenings. Traces the causation of feeble-mindedness, discusses the facts of heredity in relation to it, and gives advice in the handling of the feeble-minded.

Inquiries into Human Faculty and its Development. By Sir Francis Galton. 256 pages. Dent. 1s. net
An important work by the pioneer of eugenics, who says in his introduction that his object has been " to take note of the varied hereditary faculties of different men, and of the great differences in different families and races, to learn how far history may have shown the practicability of supplanting inefficient human stock by better strains, and to consider whether it might not be our duty to do so by such efforts as may be reasonable."

Heredity and Eugenics. By J. M. Coulter and others. 312 pages. Illus. Cambridge Univ. Press 10s.
This book, the work of leading investigators in the new science of eugenics, is written for the general public, and presents the latest conclusions in an interesting way. Several notable pedigrees of families are given.

Heredity in Relation to Eugenics. By Charles Benedict Davenport. 298 pages. Illustrated. Williams & Norgate .. .. 8s. 6d. net
In this important pioneer work, the Director of the Department of Experimental Evolution in the Carnegie Institution of Washington lays down a method, on Mendelian lines, for the study of heredity. He holds that for a long time investigation must be the watchword, and he seeks to show how the investigation may be most profitably carried on. A book of extreme interest and high value.

The Health of the State. By Sir George Newman. 200 pages. Headley .. .. .. 1s. net
An account in popular language, by an official administrator, of the rise and practice of preventive medical ideas in the sphere of social reform. The author thus describes his intention in writing : " May be looked upon in some sort as a missionary handbook, sent forth as a reminder that the physical health and fitness of the people is the primary asset of the British Empire, and the necessary basis of that social and moral reform which has for its end ' the creation of a higher type of man.' "

The Methods and Scope of Genetics. By William Bateson. Cambridge University Press. 1s. 6d. net
Genetics is Professor Bateson's name for the philosophy of heredity and variation, and this study of genetics is the author's inaugural lecture on his appointment to the Darwin Chair of Biology at Cambridge. It forms an excellent introduction to Mendelism. It embraces a vigorous and convincing advocacy of eugenics.

The Dependent, Defective, and Delinquent Classes. By C. R. Henderson. 397 pages. Harrap. 7s. 6d.
A valuable study of the social treatment of the unfit, by the Professor of Sociology in the University of Chicago. A fresh and interesting work on all forms of social endeavour.

Woman and Womanhood : a Search for Principles. By C. W. Saleeby. 398 pp. Heinemann. 10s. net
A clear and interesting study of the position of the civilised woman. The author has set out to furnish for the individual woman, and for those in charge of girls, a guide of life based upon the facts of physiology of sex. But he takes a wide and illuminating view of the subject, from the standpoint of a Eugenist.

Report of the Inter-Departmental Committee on Physical Deterioration. 177 pages. Government publication .. .. 1s. 3d.
A weighty State document which no student of national welfare can afford to ignore.

Diseases of Occupation. By Sir Thomas Oliver. 427 pages. Illustrated. Methuen .. 10s. 6d. net
A valuable survey of a rarely explored field, considered from the legislative, social, and medical points of view. The author discusses factors contributing to industrial diseases, diseases due to gases, vapours, high temperatures, atmospheric conditions, chemical and metallic poisons, dust fumes, and so on. A most important book, by one of the highest authorities on the subject.

The Bitter Cry of the Children. By John Spargo. 337 pages. Illustrated. Macmillan. 6s. 6d. net
A weighty book in the campaign against the destruction of child life, based on investigations in America, but largely international. The writer deals with the school child, the working child, the provision of pure milk, classes for girls, supervision of patent foods, abolition of child labour, etc.

The Elements of Child Protection. By Sigmund Engel. 276 pages. Allen & Unwin .. 15s. net
The author studies the whole system of child protection from the joint outlook of Socialism and Darwinism. He presents all the chief problems of his subject, and attempts to supply a solution.

Studies of Childhood. By James Sully. 535 pages. Longmans .. .. 12s. 6d. net
The author began the detailed study of the child's mind before the fashion set in in America, and his writings have done much to foster an appreciation of childish forms of intelligence. A book for parents as well as teachers.

The Psychology of Childhood. By Frederick Tracy. 186 pages. Harrap .. .. .. 2s. 6d.
What are the most important characteristics of the unfolding of a child's mental life ? How far is it conditioned by heredity, and how far by education ? What are the outstanding features of the process by which the mind comes into conscious possession of itself ? These are questions answered in this book, under the headings of the senses, intellect, feelings, will, language, æsthetic, moral, and religious ideas.

The Children of the Nation. By Sir John E. Gorst. 297 pages. Methuen .. .. .. 7s. 6d. net
The various problems concerning the welfare of children, such as their physical fitness, education, training, are here weighed and fully discussed from the point of view of their importance to the well-being of the State. The extremely bad policy of neglecting the children in any way is pointed out under every aspect.

Wastage of Child Life. By J. Johnston. 95 pages. A. C. Fifield .. .. 6d. net
A splendid little book on the awful wastage of life involved in neglected childhood. Dr. Johnston illustrates his case by conditions in Lancashire, which are, of course, exceptional. Much of the book is generally applicable to other parts, and it is a terrible book to read.

Child Life and Labour. By Margaret Alden. 148 pages. Headley Brothers .. .. .. 1s.
A very useful little book, pervaded by a fine sense of humanity. It brings together much information respecting the exploitation of child-life and its necessary defence. There are summaries, excellent for reference, of societies dealing with the subject of legislation, and books.

Problems of Boy Life. Edited by J. H. Whitehouse, M.P. 342 pages. P. S. King .. 10s. 6d. net
This volume comprises eighteen thoughtful chapters by different observers, each discussing some phase of difficulty in the case of the boy who is trying to fit himself into the great industrial world. That it is high time for the working life of the child and young person to be taken over by the public for supervision and training is made abundantly clear. The volume gains freshness from its varied authorship, each writer being an enthusiast.

Infant Mortality. By Sir George Newman. 366 pages. Methuen .. .. .. 7s. 6d. net
Brings the essential facts of this national question down to 1906, when Sir George Newman set the annual loss to Great Britain by the deaths of infants at 120,000 lives. The book shows how a high infant mortality rate almost necessarily denotes a prevalence of conditions which, in the long run, determine racial degeneration. The effects of occupation of women are traced as bearing on the death-rate, the influences of domestic and social conditions are considered, and the feeding and management of babies discussed. Preventive methods are suggested working through (1) the mother, (2) the child, (3) the environment.

The Town Child. By Reginald A. Bray. 255 pages. Fisher Unwin .. .. 3s. 6d. net
An interesting and profound study of the influences which are at work moulding the character and outlook of the town child; of the reciprocal action of environment on man and of man on environment; and of the social importance of the family life and other real small associations in which the child grows up.

Infant Mortality. By H. T. Ashby. Cambridge University Press .. .. .. 10s. 6d. net
An exceedingly able survey of the facts of infant mortality, the causes of the waste of life that occurs, and the methods by which the mortality may be lowered. The book is impressive and convincing.

The Right of the Child to be Well Born. By George E. Dawson. Funk & Wagnalls .. .. 3s.
A little book of America, the great laboratory for experiments in Eugenics, giving sane teaching for the plain man about biological and moral fitness for parenthood.

Labour and Childhood. By Margaret McMillan. 205 pages. George Allen & Unwin .. 3s. 6d.
Attempts a threefold task: first, to make clear the immediate work of the school doctor; second, to show that hitherto the only continuous education of the race has been through work and experience; and, last, to explain what is being attempted by the doctor to alter the conditions of child life.

The Task of Social Hygiene. By Havelock Ellis. 419 pages. Constable .. .. 8s. 6d. net
Discusses the problems of modern civilisation, the changing status of women, and the significance of the falling birth-rate. Eugenics and love, religion and the child, the problem of giving sexual instruction to boys and girls, are discussed.

BUSINESS

Embracing Principles, Organisation, and Methods

BUSINESS ENCYCLOPÆDIAS

The Harmsworth Business Library. By leading experts in the business world. 10 vols. 3000 pages, with many illustrations and facsimile documents Educational Book Company .. 82s. 6d. net
A thoroughly up-to-date and comprehensive work, the authors including such business organisers as Sir Joseph Lyons, Sir Thomas Lipton, Sir Thomas Dewar, and Mr. H. Gordon Selfridge.

The Business Encyclopædia and Legal Adviser. By leading experts. 9 vols. 3150 pages. The Caxton Publishing Company .. .. 66s. 6d. net
Among the contributors to this work are Sir Joseph Lyons, Mr. A. W. Gamage, Mr. Richard Burbidge, and Mr. H. F. Le Bas. Practical illustrations.

Modern Business Practice. By thirty-nine prominent authorities. 8 vols. 2000 pages. Gresham Publishing Company .. .. .. 60s. net
A comprehensive practical guide and work of reference for office, warehouse, exchange, and market.

Commercial Encyclopædia and Dictionary of Business. Edited by J. A. Slater. 4 vols. 1800 pages. Illustrations and maps. Pitman .. 30s. net
A sound business guide under an editorship that has been devoted to business literature.

Auditing, Accounting, and Banking. By Frank Dowler and E. M. Harris. (Pitman.) 5s. net.
Dictionary of Book-keeping. By R. J. Porters. (Pitman.) 780 pages. 5s. net.

LIMITED COMPANY WORK

Public Companies' Formation and Flotation. By B. O. Bircham and F. G. C. Morris. (Effingham Wilson.) 152 pages. 2s. 6d. net.
Joint Stock Companies. By J. W. Smith, LL.D. (Effingham Wilson.) 2s. 6d.
Company Accounts. A complete practical manual for the use of officials in limited liability companies. By Arthur Coles, F.C.I.S. (Pitman.) 5s. net.

Company Management. A Manual for the Daily Use of Directors, Secretaries, etc. By H. C. Emery. (Effingham Wilson.) 5s. net.
Guide to Company Secretarial Work. By O. Oldham, A.C.I.S. (Pitman.) 2s. 6d. net.
Guide for the Company Secretary. By Arthur Coles. (Pitman.) 5s. net.
The Company Secretaries' Vade Mecum. A pocket volume. (Pitman.) 2s. net.
The Chairman's Manual. By Gurdon Palin and Ernest Martin. (Pitman.) 2s. 6d. net.
The Transfer of Stocks, Shares, etc. By F. D. Head, B.A. (Pitman.) 220 pages. 5s. net.
Companies and Company Law. With the Acts of 1908 and 1913. By A. C. Connell, LL.B (Pitman.) 5s. net.
The Student's Guide to Company Law. By R. W. Holland. (Pitman.) 203 pages. 2s. 6d. net.
Student's Guide to Bankruptcy Law and Winding Up of Companies. By F. Porter Fausset, B.A., LL.B. (Pitman.) 2s. 6d. net.
Dictionary of Secretarial Law and Practice. (Pitman.) 774 pages. 25s. net.

COMMERCIAL AND MERCANTILE LAW

A Handbook of Commercial Law. By F. G. Neave, LL.D. (Effingham Wilson.) 3s. 6d. net.
The Elements of Commercial Law. By H. W. Disney, B.A. (Macdonald & Evans.) 2s. 6d.
The Elements of Commercial Law. By A. H. Douglas, LL.B. (Pitman.) 128 pages. 1s. net.
The Commercial Law of England. By J. A. Slater, B.A., LL.B. (Pitman.) 227 pages. 2s. 6d.
Pitman's Mercantile Law. By J. A. Slater. (Pitman.) 448 pages. 5s. net.
The Law Relating to Trade Customs, Marks, Secrets, etc. By Lawrence Duckworth. (Pitman.) 116 pages. 1s. net.
The Law of Carriage. By J. E. R. Stephens, B.A. (Pitman.) 5s. net.
The Law of Contract. By R. W. Holland, M.A. (Pitman.) 120 pages. 1s. 6d. net.
Law and Practice of Bankruptcy. By G. L. Hardy. (Effingham Wilson.) 2s. 6d. net.
The Student's Guide to Bankruptcy Law and Winding Up of Companies. By F. Porter Fausset, B.A., LL.B. (Pitman.) 2s. 6d. net.
Bankruptcy Deeds of Arrangement and Bills of Sale. By W. V. Ball, M.A. (Pitman.) 5s. net.
Legal Terms, Phrases, and Abbreviations. (Pitman.) 2s. 6d.

STOCK EXCHANGE AND MONEY MARKET

Stockbroker's Office Organisation, Management, and Accounts. By J. E. Day. (Pitman.) 242 pages. 7s. 6d. net.
A Money-Market Primer. By George Clare. (Effingham Wilson.) 177 pages. 5s. net.
A Plain Guide to Investment and Finance. By T. E. Young, B.A. (Macdonald & Evans.) 5s.
The Money and the Stock and Share Markets. By Emil Davies. (Pitman.) 120 pages. 1s. net.
The History, Law, and Practice of the Stock Exchange. By A. P. Poley, B.A., and F. C. Gould. (Pitman.) 5s. net.
Guide to the Stock Exchange. By W. G. Cordingley. (Effingham Wilson.) 2s. net.
Dictionary of Stock Exchange Terms. By W. G. Cordingley. (Effingham Wilson.) 2s. 6d. net.

PRICES OF BOOKS

In all cases the prices in this list are the maximum prices, and in many cases, whether indicated or not, there may be a discount of threepence in the shilling. Almost invariably shilling books, and nearly all technical works, are *net*.

PHYSICS AND POWER

Embracing the Science of Physics, Forms of Power, and Prime Movers.

See also Chemistry and Electricity

The New Physics and its Evolution. By Lucien Poincaré. 344 pages. Kegan Paul .. .. 5s.
A very valuable review of the results at which physicists have been arriving during the last ten years or so. The author tries to show how the ideas prevailing today have been formed by tracing their evolution and transformations. Questions that remain in a confused state are put on one side.

Textbook of the Principles of Physics. By A. Daniell. 782 pages. Illus. Macmillan .. 17s.
This very comprehensive work, by a barrister who is one of the most widely learned students of our generation, deals systematically with the entire science. It is highly condensed, and is designed for the advanced learner rather than for the beginner. There is a good bibliography. Among its subjects are: The properties of matter, the problems of time and space, the nature of work and energy, and the sciences of heat, light, electricity, and magnetism.

The Evolution of Forces. By Gustave le Bon. 388 pages. Illustrated. Kegan Paul .. .. 5s.
Dr. le Bon illustrates in this book his theory that the atom is a great reservoir of energy, and the source of most of the forces of the universe. The further study of radiations, phosphorescence, and the Hertzian waves is tending rapidly to the acceptance of this theory.

Scientific Ideas of Today. By C. R. Gibson. 344 pages. Illustrated. Seeley .. .. 5s. net
A very popular yet truly scientific exposition of subjects such as atoms, electricity, ether, magnetism, light, colour, radium, gravitation, etc. As readable as a really good story.

The New Knowledge. By Robert Kennedy Duncan. Illustrated. Hodder & Stoughton. ... 6s. net
A popular account of the new physics and the new chemistry in their relation to the new theory of matter. Deals with the discoveries of Monsieur Curie, J. J. Thomson, Ernest Rutherford, and Frederick Soddy in a readable and instructive way.

The Recent Development of Physical Science. By W. C. D. Whetham. Illus. John Murray ... 5s.
This book brings together in concise form much of the new knowledge of our time, dealing with the philosophical basis of physical science, the liquefaction of gases, and the absolute zero of temperature, fusion and solidification, the problems of solution, the conduction of electricity through gases, and radio-activity.

Advanced Exercises in Practical Physics. By Arthur Schuster and Charles H. Lees. 376 pages. Illustrated. Cambridge University Press .. 8s.
Intended for students who have obtained an elementary knowledge of experimental work in physics and desire to become acquainted with the principles and methods of accurate measurement. Selected and typical exercises are given, with a view to encouraging accurate work.

The Ether of Space. By Sir Oliver Lodge. 156 pages. Illustrated. Harper .. .. 2s. 6d. net
A short book, describing the nature and properties of the ether. Necessarily somewhat technical, but enabling the ordinary reader to realise the wonder of the subject, as, for example: "Every cubic millimetre of the universal ether must possess the equivalent of 1000 tons, and every part of it must be squirming internally with the velocity of light."

A History of the Cavendish Laboratory, Cambridge. 342 pages. Illustrated. Longmans 7s. 6d. net
A book in celebration of the twenty-fifth year of Sir J. J. Thomson's tenure of the Cavendish professorship. Gives the story of the building of the laboratory by the Duke of Devonshire, and the work done in it under Clerk-Maxwell, Lord Rayleigh, and Sir J. J. Thomson. There is no post in the world which has been held successively by three men of such supreme genius. Their experiments, ideas, and teaching have changed the foundations of some important branches of science.

The Corpuscular Theory of Matter. By Sir J. J. Thomson. 172 pages. Constable .. 7s. 6d.
Describes the author's famous experiments that resulted in the breaking up of the atom into electrons or corpuscles, consisting of charges of negative electricity. One of the master-works of modern science, originally delivered in the form of lectures at the Royal Institution. Difficult in places for the general reader.

Matter and Energy. By Frederick Soddy. 253 pages. Williams & Norgate .. .. 1s.
This little book, by the lecturer in physical chemistry and radio-activity of the Glasgow University, deals in a clear and simple way with the recent discoveries which have united the sciences of physics, chemistry, and electricity.

Physical Properties of Gases. By A. L. Kimball. 238 pages. Illustrated. Heinemann .. 5s.
A popular introduction to the subject, from Johns Hopkins University, in the U.S.A. Not a schoolbook. Deals with pressure, buoyancy, elasticity, expansion, high vacua, diffusion, thermo-dynamics, radiant matter, etc.

Liquid Air, Oxygen, and Nitrogen. By Georges Claude. Translated by H. E. P. Cottrell. 418 pages. Illustrated. Churchill .. .. 18s. net
Gives a sketch of the attempts to reduce gases to a liquid state, and the various commercial processes for the liquefaction of air. Discusses the properties of liquid air, and the part played by Dewar in inventing the means of storing it. A practical work.

The Becquerel Rays and the Properties of Radium. By Hon. R. J. Strutt. Illustrated. Arnold. 8s. 6d.
Written with the object of giving a clear and simple account of the phenomena of radio-activity without sacrificing accuracy of statement. Intended for the general reader with little or no previous scientific knowledge. Ends with a chapter on the electrical theory of the nature of matter.

Studies in Radio-Activity. By W. H. Bragg. 196 pages. Illustrated. Macmillan .. .. 5s. net
An account at first-hand of some very interesting experiments with X-rays and similar rays emitted by radium. Professor Bragg contends that these rays are not waves or pulses of electro-magnetic energy, but minute particles of matter. This theory, however, has been overthrown by the discovery that X-rays are very small electric waves.

Radio-Active Substances and their Radiations. By E. Rutherford. 699 pages. Illustrated. Cambridge University Press .. .. .. 15s. net
The most complete and up-to-date work on the subject. Gives the new methods of counting the particles, and deals with the absorption of radiations by matter. Describes the numerous radio-active substances now known, and ends with a chapter on the radio-activity of the earth and atmosphere. A classic work, by a master of the subject who has made this study especially his own, and is a supreme authority.

The Atomic Theory. By A. Wurtz. 344 pages. Kegan Paul .. .. 5s.
A review and discussion of the growth of the atomic theory, noting the work done by successive investigators, but written rather for the student than for the general reader.

Radio-Activity and Geology. By J. Joly. 287 pages. Illustrated. Constable .. 7s. 6d. net
An account of the influence of radium and other forms of radio-active energy on the history of the earth. Shows how Lord Kelvin's estimate of twenty million years for the age of the earth has been upset by modern discoveries. An interesting and clearly written account of the problem.

The Radio-Active Substances, their Properties and Behaviour. By Walter Makower. Kegan Paul. 5s.
One of the most recent additions to the International Scientific Series, dealing with some of the latest phases of scientific investigation. It attempts to prevent the chief phenomena and theories relative to radio-activity, and to serve as an introduction to the subject for students of both physics and chemistry. The subject is treated simply, and, as far as possible, without mathematical analysis.

Light. By E. J. Houston. 349 pages. Illustrated. Chambers .. .. 2s. 6d. net
A book for beginners, dealing with such popular subjects as reflection and refraction; looking-glasses and burning-glasses; the kaleidoscope, the microscope and the camera; eye-glasses and the human eye; lamps and incandescent lights; the X-rays; the spectrum in rainbows; lighthouses and searchlights.

Light, Visible and Invisible. By Silvanus P. Thompson. 294 pages. Illustrated. Macmillan. 6s. net
A brilliant, simply worded, and scientific account of ordinary light, the invisible part of sunlight, and cathode rays and Röntgen rays. The standard book on the subject of a popular sort, written by a first-rate man of science who has the art of explaining difficult things in a graceful and easy way.

Elementary Physical Optics. By W. E. Cross. 312 pages. Clarendon Press .. .. .. 3s. 6d.
An attempt by a teacher to present the difficult study of light in the most practical way. The aim of the author has been to make the subject really educative instead of introducing problems that may be solved mechanically.

Light and Photography. By H. Vogel and A. E. Garrett. Illustrated. Kegan Paul .. 12s. 6d.
An historical sketch of the discovery of photography, followed by a study of the chemical action of light, a description of lenses, plates and films, and camera appliances. Then a discussion of the art of photography and the three-colour process leads to the latest developments of Röntgen rays and micro-photography, photo-telegraphy, and the cinematograph.

The Pressure of Light. By J. H. Poynting. Illustrated. S.P.C.K. .. .. 2s.
An interesting monograph, by the Professor of Physics at Birmingham, on the recently discovered pressure which is exercised by light. Probably this pressure, which was hitherto entirely unsuspected, will greatly alter scientific views with regard to the propagation of light.

Spinning Tops. By John Perry. S.P.C.K. 2s. 6d.
A vivid introduction to the study of the principles of rotation, which govern equally the movements of the solar system, the gyrostat which steadies the torpedo, and the child's spinning-top.

Light for Students. By Edwin Edser. 579 pages. Illustrated. Macmillan .. .. .. 6s.
A classic work, by a master of the subject who has made this study his own, and is a supreme authority.

Colour in Nature. By Marion I. Newbigin. 344 pages. John Murray .. .. .. 7s. 6d.
An attempt to set forth the main known facts in regard to the pigments and colours of plants and animals. It treats of the deeper problems of the subject, but the style in which this is done is lucid and attractive. A collection of wonderful facts and incomplete theories.

Heat, a Mode of Motion. By John Tyndall. 591 pages. Illustrated. Longmans .. .. 12s.
No book written by Tyndall explains his great popularity as a lecturer and writer so clearly as this. It is graphic, experimental, instructive; but, more than that, it has the glow of enthusiasm which kindles feeling. The avowed object of it was to arouse interest as well as to impart knowledge, and this it does by tingeing all its pages with the personality of the teacher.

Lectures on Sound. By John Tyndall. 335 pages. Illustrated. Longmans .. .. .. 10s. 6d.
An attempt to render the science of sound interesting to persons who do not possess any special scientific culture. The subject is treated throughout by experiment, and Tyndall writes so vividly that the reader realises each description as an actual operation. One of the standard books on the subject, by a man who was a master of literary effect as well as of scientific knowledge.

Evolution of the Thermometer. By Henry Carrington Bolton. 96 pages. Williams & Norgate 4s. 6d.
Traces the successive steps in the history of the evolution of the thermometer from its first beginnings in Italy at the end of the sixteenth century, through its crude early forms, down to the three standards now commonly used in all civilised lands. With a chronological epitome and a good list of authorities. A little volume packed with facts.

The Theory of Sound. By Baron Rayleigh. Two vols. Illustrated. Macmillan .. .. 24s. net
A highly technical and mathematical study of acoustics, suitable only for advanced students.

Textbook on Sound. By Edwin H. Barton. 687 pages. Illustrated. Macmillan .. 10s. net
